*Bifidobacterium breve* is a common inhabitant of the infant gut and its presence has been correlated with particular health-promoting effects, such as enforcement of the intestinal barrier, activation/modulation of the host's immune response and protection against particular infections.

**Objectives**

Genome sequencing of *B. breve* JCM 7017 revealed the presence of the first verified bifidobacterial megaplasmid pMP7017 (190 kb of size). The objective of this study was to provide evidence of its horizontal transmission between strains of the same and/or different (bifido)bacterial species by means of a predicted conjugative machinery.

**Methods**

DNA sequencing was performed using Next Generation Sequencing platforms. The *in silico* predictions were performed using BLAST and PFAM databases as well as additional bioinformatics tools (e.g prodigal, tRNAscan, CRISPR and GCUA). Proof of conjugal transfer was obtained by demonstrating the presence of the megaplasmid using Pulsed Field Gel Electrophoresis in combination with S1 nuclease treatment.

**Conclusions**

*In silico* characterization of the megaplasmid revealed several genomic features supporting a stable establishment in its host, illustrated by predicted CRISPR-Cas functions that are known to protect the host against intrusion of foreign DNA. Interestingly, pMP7017 is also predicted to encode a conjugative DNA transfer apparatus and consistent with this notion we demonstrate conjugal transfer of pMP7017 to representative strains of *B. breve* and *B. longum* subsp. *longum*. We furthermore demonstrate the presence of a megaplasmid with homology to pMP7017 in three *B. longum* subsp. *longum* strains, indicating that similar elements are also naturally present in other bifidobacterial species, thereby supporting our proof of cross-species transfer.

**EXPLORING THE INFLUENCE OF CHEMOTACTIC PREFERENCES ON  
SUBSTRATE COMPETITION AND COMMUNITY FATE BY IN SILICO MODELING**

F. Centler<sup>1</sup>, M. Thullner<sup>1</sup>

<sup>1</sup>*Department of Environmental Microbiology,  
UFZ - Helmholtz Centre for Environmental Research, Leipzig, Germany*

**Background**

Competition for substrate is a common mode of microbial interaction in natural environments. Both, growth and motility phenotype influence competition, with the former having been studied well, while the latter has received less attention.

**Objectives**

To elucidate the impact of microbial motility on competition, we focus on microbial communities in which two strains populating a homogeneous environment compete for a substrate. Strains share identical growth phenotypes but differ in their chemotactic preference, either responding more sensitively to substrate or to a chemoattractant that is excreted by the cells themselves. By systematically varying chemotactic preferences of the competing strains, we assess the impact of each chemotactic preference on competition and on overall community fate.

**Methods**

Microbial communities are simulated using an individual-based modelling approach. Competing strains are initially homogeneously populating a two-dimensional environment. Microbial growth and motility including random movement and chemotaxis towards substrate and microbial cells, and substrate diffusion are simulated, and the resulting spatio-temporal microbial distribution patterns are observed and analyzed.

**Conclusions**

Results show that, depending on the combination of chemotactic preferences, microbial distributions remained homogeneous or transient or permanent spatial patterns emerged. The presence of a competing strain is able either to suppress or to induce aggregate formation, indicating more complex interactions beyond simple substrate competition. Strains being more attracted to self-excreted compounds tend to form aggregates of high densities where starvation conditions prevail, leading communities to become dominated by the competing strain. The model indicates a mechanism by which aggregate formation can evolve, even if it is initially disadvantageous.

## **INDIVIDUAL-BASED MODELLING OF THE IMPACT OF INITIAL EVENNESS ON THE PRESERVATION OF BIODIVERSITY FOR IN SILICO BACTERIAL COMMUNITIES**

A. Daly<sup>1</sup>, J.M. Baetens<sup>1</sup>, B. De Baets<sup>1</sup>

<sup>1</sup>*Mathematical Modelling Statistics and Bioinformatics, Ghent University, Ghent, Belgium*

### **Background**

One of the most important aims in ecology is to identify and comprehend the mechanisms that sustain biodiversity - often critically important for ecosystem viability. Many theoretical models have shown that species in competition can coexist – thus maintaining the ecosystem's biodiversity - if ecological processes such as competition and mobility occur on a local scale [1]. This is also true in the case of communities with non-transitive competition between species, the classical example being the rock-paper-scissors game.

### **Objectives**

Initial community evenness has been shown to be a key factor in preserving ecosystem functional stability [2], but has not been accounted for in previous modelling studies. We formulate a model that allows initial community evenness to be varied in order to investigate the consequent impact on ecosystem biodiversity.

### **Methods**

We consider an ecosystem of four interacting bacterial species, and present a stochastic, spatial individual-based model simulating the ecosystem dynamics. Interactions take place on a two-dimensional lattice. Three processes are incorporated: reproduction, competition and mobility. In addition to variable initial evenness, multiple competition schemes are implemented, modelling various possible communities, resulting in diverse coexistence and extinction scenarios.

### **Conclusions**

Simulations show that long-term ecosystem behaviour is strongly dependent on initial evenness and competition structure. The ecosystem is generally unstable; higher initial evenness has a small stabilizing effect on ecosystem dynamics by extending the time until the first extinction.

**MECHANISM BASED PHARMACODYNAMIC MODELING OF GROWTH  
INHIBITION IN BACTERIA**

C. Hethey<sup>1</sup>, C. Klotz<sup>2</sup>, W. Huisinga<sup>3</sup>

<sup>1</sup>*Computational Physiology Group,*

*Institut für Biochemie und Biologie Universität Potsdam, Potsdam, Germany*

<sup>2</sup>*Dept. Clinical Pharmacy & Biochemistry, Institute of Pharmacy, Berlin, Germany*

<sup>3</sup>*Computational Physiology Group, Institut für Mathematik Universität Potsdam,  
Berlin, Germany*

**Background**

Antibiotic activity is assessed in vitro by quantifying the reduction of growth of a bacterial culture. Growth can be described as change in cell number on population level. On the single-cell level, physiological properties like cell size before division or translational capacity vary with growth rates: Cells adapt to their environment. Typical drug-effect models link population growth directly to the exposure of antibiotics. They rarely account for known mechanisms of action of the drug - which are particularly relevant for the analysis of synergistic or antagonistic effects of drug combinations.

**Objectives**

Development of a pharmacodynamic model which allows for mechanistic integration of antimicrobial effects on the cellular level to predict bacterial growth.

**Methods**

Control experiments without drug resulted in baseline values for population growth. An established single cell model predicted cell level parameters from this growth rate. Induction of cell killing and growth inhibition were linked to known drug characteristics (minimal bactericidal / inhibitory concentration). A transit compartment cell-cycle model integrated time dependent cellular adaptation processes. Two bacterial subpopulations were considered (resting and growing). We validated our model for predicting time-kill curves with *E. coli* exposed to tetracycline. Furthermore we predicted septation dynamics of *B. subtilis* during a shiftdown from exponential to stationary phase.

**Conclusions**

Since both scenarios show good agreement between predicted and experimental data, these promising results are a first step to mechanistically model bacterial growth during exposure to multiple antibiotics.

## **INFLUENCE OF ACTIVE SITE GROOVE VOLUME ON DD-CARBOXYPEPTIDASE ACTIVITY OF *E. COLI* DACD**

D. Kar<sup>1</sup>, A. Bansal<sup>1</sup>, S. Chakraborty<sup>2</sup>, A. Ghosh<sup>1</sup>

<sup>1</sup>Biotechnology, Indian Institute of Technology Kharagpur, Kharagpur, India

<sup>2</sup>Biological Science, Tata Institute of Fundamental Research, Mumbai, India

### **Background**

*E. coli* DacD is a DD-carboxypeptidase, having much weaker DD-CPase activity than PBP5. The reason for such a weak DD-CPase activity of DacD and its importance within an *E. coli* cell is unknown.

### **Objectives**

Deciphering the role of active-site groove volume (AGV) on DD-CPase activity of *E. coli* DacD.

### **Methods**

Here, we generated the 3D model of DacD using homology modeling and analysed the binding of specific substrates within AGV. Interestingly, the AGV of DacD is about one-third of PBP5 and such a low AGV might reduce the catalytic efficiency of DacD. To validate the result *in silico*, we mutated the secondary amino-acid residues around the DacD active-site by incorporating several transitional and transversional mutations and observed for the changes developed in the AGV. Such mutations brought a 70% increase in the mutant DacD AGV. PBP5 has higher AGV that can be correlated with DD-CPase activity. In addition, we superimposed PBP5 active-site onto mutated DacD and observed a similar geometric arrangement. Furthermore, the pentapeptide-binding affinity of the mutant DacD was increased as revealed by molecular docking analyses. Higher binding affinity of the mutant DacD towards peptidoglycan mimetic pentapeptide substrate possibly signifies a greater DD-CPase activity.

### **Conclusions**

Active-site groove volume may act as a determinant for DD-CPase activity and the reduced DD-CPase activity of DacD is possibly due to its inadequate active-site groove volume.

**FEMS-3082**  
**(Human) microbiome**

**TRANSCRIPTIONAL AND POST-TRANSCRIPTIONAL REGULATION OF PST2  
OPERON EXPRESSION IN VIBRIO CHOLERAЕ 01**

D. Leite<sup>1</sup>, N. Mantuano<sup>1</sup>, C.L. Goulart<sup>1</sup>, L.C. Barbosa<sup>1</sup>, G.C.V. Costa<sup>1</sup>, P.M. Bisch<sup>1</sup>,  
W.M.A. von Kruger<sup>1</sup>

<sup>1</sup>*Institute of Biophysics Carlos Chagas Filho, Federal University of Rio de Janeiro,  
Rio de Janeiro, Brazil*

**Background**

The most abundant periplasmic protein of *Vibrio cholerae* grown under inorganic phosphate (Pi) limitation is the high affinity Pi transporter, PstS, of the Pst2 system. It is encoded by *pstS* of the *pst2* operon, *pstSABC*, member of *V. cholerae*'s Pho regulon. Little is known about the regulation of *pst2* expression and the non-stoichiometric production of its genes products.

**Objectives**

To elucidate the regulatory mechanisms behind *pst2* expression in *V. cholerae*.

**Methods**

Bioinformatics analysis: Clustal Omega for protein sequences alignment, Mfold for the determination of RNA secondary structures and the corresponding free energy values and MEME/MAST to search for putative Pho boxes. Experimental procedures: SDS-PAGE and MS *ESI-Q-ToF Micro* for protein analysis and identification and promoter-*lacZ* fusion, RNA extraction, cDNA synthesis, endpoint-PCR and quantitative Real-Time PCR for the expression analysis.

**Conclusions**

Based on the bioinformatics analysis we proposed new start codons for *pstS* and *pstC*, a regulatory region upstream *pstS* containing potential Pho boxes and a *pstS-pstC* intergenic region, distinct from those predicted. Moreover, sequences able to form stem-loop structures followed by potential RNase E-cleavage sites were detected in the intergenic regions *pstA-pstB* and *pstS-pstC*. The experimental analyses demonstrated that *pst2* is transcribed under Pi limitation in a PhoB-dependent manner as a full-length mRNA that is processed into minor transcripts of distinct stabilities. The most stable is the *pstS*-encoding mRNA, followed by *pstB*, *pstA* and *pstC* specific transcripts. The abundance of PstS relative to the other components of Pst2 system in *V. cholerae* seems to correlate to the higher stability of its transcript.

**MICROBE ATLAS: A GLOBAL INTEGRATED MAP OF MICROBIAL DIVERSITY**

J.F. Matias Rodrigues<sup>1</sup>, T.S.B. Schmidt<sup>1</sup>, J. Tackmann<sup>1</sup>, C. von Mering<sup>1</sup>

<sup>1</sup>*Institute of Molecular Life Sciences, University of Zurich, Zurich, Switzerland*

**Background**

The world's microbial diversity is vast and the majority of microbes do not readily grow in culture, complicating the analysis and interpretation of this diversity. In addition, the lack of a unified and consistent annotation of the world's microbial diversity has so far impeded a comprehensive comparative analysis.

**Objectives**

The "Microbe Atlas", a global metaresource of all publicly available environmental marker gene sequence data, which will be available as a web resource. A dataset consisting of 212'000 samples with more than 3 billion identified small subunit ribosomal RNA sequences. This resource will enable a better understanding of what are the typical and atypical microbial taxa in samples, by establishing compositional baselines in terms of microbes that are often found in similar environments.

**Methods**

An analysis of all publicly available environmental marker gene sequence data.

**Conclusions**

This resource should become an essential tool for microbial biologists wishing to compare their samples to previously sequenced microbial communities, and identify both the typical as well as atypical microbial taxa in their samples.

**FEMS-1143**  
**(Human) microbiome**

**LACCASE FROM PATHOGENIC GUT BACTERIA FACILITATE BIOTRANSFORMATION OF NON-STEROIDAL ANTI-INFLAMMATORY DRUGS (NSAIDS)**

D. Singh<sup>1</sup>, S. Rawat<sup>1</sup>, K.K. Sharma<sup>1</sup>

<sup>1</sup>Microbiology, Maharshi Dayanand University, Rohtak, India

**Background**

Non-steroidal anti-inflammatory drugs (NSAIDs) are used in the treatment of pain, inflammation, cardiovascular diseases, arthritis and cancer by inhibiting cell proliferation. Laccases (EC 1.10.3.2) are multicopper oxidases (MCO), recently reported from *Escherichia coli*, *Salmonella enterica*, *Camylobacter jejuni*, *Pseudomonas aeruginosa* with role in copper homeostasis, iron acquisition, manganese oxidation and in pathogenesis.

**Objectives**

To find out novel laccase from different serotypes of *Yersinia enterocolitica* and clone it into a suitable expression vector for the biotransformation of NSAIDs.

**Methods**

Amplified laccase gene (*yack*) from different serotypes of *Y. enterocolitica* was cloned in pTZ57R/T vector using TA cloning method. The positive clones were sequenced to confirm *yack* and construct a phylogenetic tree using Mega 5.0. Further, *yack* was subcloned into the desired restriction sites of pET28a expression vector and transformed into *E. coli* BL21 (DE3) expression host. The recombinant protein was refolded and purified using His-spin protein miniprep kit, for the biotransformation of aspirin and diclofenac (NSAIDs), which validates our *in silico* studies.

**Conclusions**

Laccase from different strains of *Y. enterocolitica* can be used as a taxonomic tool as it showed serotype specific clades. The HPLC analysis of laccase treated diclofenac and aspirin showed complete biotransformation after 24h of incubation. The FTIR results suggested a change in C-C and C-N bonds. Laccase transform NSAIDs and may have a significant role in the colonization of laccase positive gut microflora.

## **RELATIONSHIPS BETWEEN MICROBIAL GENE CONTENT, PHYLOGENETIC DIVERGENCE AND ENVIRONMENTAL PREFERENCES**

J. Tamames<sup>1</sup>, P.I. Nikel<sup>1</sup>, C. Pedrós-Alió<sup>1</sup>

<sup>1</sup>*Systems Biology Department, Centro Nacional de Biotecnología, Madrid, Spain*

### **Background**

Environmental characteristics impose some particular constraints to the species living in any given habitat. In many instances, prokaryotic taxa show environmental preferences that shape the diversity found in diverse different environments. It is reasonable to expect that these habitat preferences have a reflection on the metabolism of the prokaryotic organisms. All these metabolic choices require particular sets of genes, and, therefore, gene content is determined to some extent by environmental preferences. But it is unclear to what extent is this relationship determinant, or how extensive is the metabolic rearrangement leading to different environmental adaptations.

On the other hand, it seems obvious that genomic content is determined highly by phylogenetic proximity. The extent to which each of the two processes modulates the genomes has not been quantified.

### **Objectives**

We present a comprehensive analysis of the relationships between phylogeny, metabolism and environmental similarity in the prokaryotic world. We aim to quantify the influences of phylogenetic descent and environmental preferences in genomic content, to answer the question of how much it is shaped by each of the contributions.

### **Methods**

We have calculated measures of phylogenetic, genomic and environmental distances between pairs of prokaryotic taxa using their 16S distances, common gene content and environmental preferences.

### **Conclusions**

The results indicate a strong influence of the phylogeny in the genomic content, although the influence of the environment is notable for some particular metabolic

classes. This allowed to discover sets of genes that can act as environmental markers and predictors of the possible habitats for new species.

**DISCOVERY OF PUMILARIN, A NOVEL HEAD-TO-TAIL CYCLIZED PEPTIDE, BY BAGEL3**

A. van Heel<sup>1</sup>, M. Montalbán-López<sup>1</sup>, O.P. Kuipers<sup>1</sup>

<sup>1</sup>Molecular Genetics, University of Groningen, Groningen, Netherlands

**Background**

In the post-genomic era the amount of (public) genomic data is ever increasing. Bacteriocin mining tools can be used to extract valuable information from this data regarding the presence of post-translationally modified peptides.

**Objectives**

As a proof of principle we mined all publicly available bacterial genomes using Bagel3. For simplicity we limited the results to head-to-tail cyclized peptides only. We found a large variety of these (predicted) circular peptides in the *Bacillus* genus. Based on the mining results we screened several *Bacillus pumilus* strains for the production of novel (head-to-tail) bacteriocins.

**Methods**

This yielded the production of a novel bacteriocin that we call pumilarin. The overall homology with AS-48 is about 50%. We purified pumilarin using protocols that are based on AS-48 purification methods.

**Conclusions**

Next we analysed its structure using mass-spectrometry and found that its mass was in accordance with its circular structure. After fragmentation masses could be observed that could be explained only by N- to C-terminal linkage of the peptide. The activity spectrum of pumilarin was benchmarked against the prototype head-to-tail cyclized bacteriocin AS-48 and found to show some interesting differences in spectrum.

**MATHEMATICAL MODELLING OF BACTERIAL CROSS-FEEDING:  
APPLICATION IN THE HUMAN INTESTINAL TRACT**

A.S. Van Wey<sup>1,2</sup>, N.C. Roy<sup>1,2</sup>, P.R. Shorten<sup>1,2</sup>

<sup>1</sup>*AgResearch Ltd, New Zealand*

<sup>2</sup>*Massey University, Riddet Institute, New Zealand*

**Background**

In nature bacteria are rarely found in isolation, rather they reside in close association and are commonly found within biofilms. Bacteria that develop alternative feeding mechanisms, such as cross-feeding, have a much greater chance of survival in a competitive environment. In the human intestinal tract, the many types of cross-feeding include the use of oligosaccharides and/or monosaccharides resulting from extracellular degradation of polysaccharides by a competing bacterium, the use of such molecules along with metabolites produced by other bacteria and solely using metabolites produced closely associated bacteria.

**Objectives**

We aimed to develop models to describe the three aforementioned types of microbial cross-feeding and use those models to understand the cross-feeding phenomenon.

**Methods**

We developed a system of mechanistic differential equations to describe the different types of bacterial cross-feeding. These models were fit to multi-response data found in the literature using nonlinear regression. The multi-response data included bacterial growth (*Bacteroides*, *Bifidobacterium*, *Eubacterium*, *Roseburia*), substrate degradation (inulin, oligofructose, fructose, and metabolites), and metabolite concentrations (succinate, acetate, lactate and butyrate). To ensure that the estimated model parameters were independent of scale, we minimized the diagonal of the matrix  $ZTZ$ , where  $Z$  is the residual matrix formed from the data and model fit.

**Conclusions**

Our results suggest that microbial cross-feeding follows second-order chemical kinetics even when the ratios of two substrates are not one-to-one.

## **COMPARATIVE GENOMIC ANALYSIS REVEALS SUBTELOMERIC GENE DUPLICATIONS AND METABOLIC POTENTIAL OF THE KLUYVEROMYCES GENUS**

J. Varela<sup>1</sup>, K. Wolfe<sup>2</sup>, J. Morrissey<sup>1</sup>

<sup>1</sup>Microbiology, University College Cork, Cork, Ireland

<sup>2</sup>School of Medicine & Medical Science, University College Dublin, Dublin, Ireland

### **Background**

The yeasts *Kluyveromyces lactis* and *Kluyveromyces marxianus* are the best-studied species of the *Kluyveromyces* genus. *K. lactis* has been adopted as a model for non-*Saccharomyces* yeasts whereas *K. marxianus* is more widely used for a range of different industrial applications because of relevant phenotypic traits. A *K. lactis* genome sequence has been available for some time but only recently genome sequences for a number of different *K. marxianus* strains have been generated.

### **Objectives**

Our aim to understand the genetic basis of the metabolic and physiological differences between *Kluyveromyces* and *Saccharomyces* and within the *Kluyveromyces* genus.

### **Methods**

We compared the proteomes of *K. marxianus*, *K. lactis* and *S. cerevisiae* by protein clustering using OrthoMCL. We found 4,119 common clusters (in all 3 yeasts) and 596 exclusively shared by the two *Kluyveromyces* species. More detailed bioinformatics as well as phenotypic assays were carried out to verify the findings.

### **Conclusions**

Some key differences arise in sub-telomeric regions, where the same genes can be found duplicated at each end of the chromosome or at the ends of a separate chromosomes. For example, the genes responsible for lactose assimilation are duplicated in the subtelomeric regions of *K. marxianus* but not in *K. lactis*. Indeed, detailed comparison this duplicated region in different *K. marxianus* strains identifies variation that may account for some of the phenotypic differences in lactose assimilation between strains. Other differences that give rise to phenotypic variation

between species have also been verified and new metabolic pathways identified in *K. marxianus*.

**COMPARATIVE GENOMIC ANALYSIS OF NINE SPHINGOBIUM STRAINS:  
INSIGHTS INTO THEIR EVOLUTION AND HEXACHLOROCYCLOHEXANE (HCH)  
DEGRADATION PATHWAYS**

H. Verma<sup>1</sup>, R. Kumar<sup>1</sup>, P. Oldach<sup>1</sup>, N. Sangwan<sup>1</sup>, J.P. Khurana<sup>2</sup>, J.A. Gilbert<sup>3</sup>, R. Lal<sup>1</sup>

<sup>1</sup>Zoology, University of Delhi, Delhi, India

<sup>2</sup>Plant Molecular Biology, University of Delhi, Delhi, India

<sup>3</sup>Ecology and Evolution, University of Chicago, Chicago, USA

**Background**

Species belonging to the genus *Sphingobium* are well known for their ability to degrade hexachlorocyclohexane (HCH) isomers due to the presence of *lin* pathway genes. However, the establishment of the *lin* pathway in sphingomonads under HCH pressure is still unknown.

**Objectives**

Here, the nine *Sphingobium* spp. (strains LL03, DS20, IP26, HDIPO4, P25 and RL3, B90A, UT26S and *Sphingobium* sp. SYK6) were compared in order to reveal the mode of acquisition of *lin* genes.

**Methods**

Genomes of *Sphingobium* spp. were assembled using ABySS1.3.3 followed by their validation with bwa0.5.9. Phylogeny was constructed with 16S rRNA, single copy genes, ANI and tetranucleotide frequency. Further, draft genomes were annotated using Glimmer-3 at RAST4.0 server. Orthologs were identified using CD-HIT and all versus all BLAST. Functional annotation was performed using KAAS and gene families were predicted using Minpath. dN/dS and dS for each gene pair was calculated using Hyphy2.1.2.

**Conclusions**

The phylogenetic analysis using genomic data clustered efficient HCH degraders in a closely related group comprising of UT26S, B90A, HDIPO4 and IP26, where HDIPO4 and IP26 were classified as subspecies with ANI value >98%. Total gene content shared among all nine strains was ~10% which increased to ~25% in eight HCH-associated strains. Additionally, an inter-genus plasmid pool between genus *Sphingobium* and *Sphingomonas* was observed. Further, the differences in *lin* gene sequences, copy number and arrangement with respect to IS6100 revealed possible

evolutionary acquisition mechanisms for this pathway. This study also reflected that HDIPO4, IP26 and B90A are better suited organisms for HCH bioremediation.

**DIVERSITY OF SURFACE-ASSOCIATED BACTERIA AND ANTIBACTERIAL ACTIVITY OF THE MARINE SPONGES COLLECTED FROM MARINE AREAS OF TURKEY**

*G. Altug<sup>1</sup>, P. CIFTCI TURETKEN<sup>1</sup>, S. GURUN<sup>1</sup>, S. KALKAN<sup>1</sup>, B. TOPALOGLU<sup>1</sup>*

*<sup>1</sup>Marine Biology, Istanbul University Faculty of Fisheries, ISTANBUL, Turkey*

**Background**

Increasing resistance problem of human pathogenic bacteria against commercial antibiotic derivatives has become important problem of all over the world.

**Objectives**

Anti-bacterial activity of the methanolic extracts of the marine sponges against pathogenic bacteria and diversities of sponge-associated and free-living bacteria were investigated.

**Methods**

Taxonomic designations of the sponges were carried out using histological sample preparation technique. The samples were extracted using cold methanol extraction technique. The agar disc diffusion method was used to determine the anti-bacterial activity of the sponge extracts. The pure bacterial strains isolated from the sponges were identified using the automated micro identification system VITEK2 Compact30.

**Conclusions**

The methanolic extracts of all tested sponges displayed positive antibacterial activity at varying levels against pathogenic bacteria. Antibacterial effectiveness rate was found higher in the samples which were collected from the Aegean Sea than the Sea of Marmara. The community profiles of the sponge associated bacteria were found different from free-living bacteria. Though similar bacteria species were found in all sponge samples, the predominant bacterial community profiles were different. Of the 325 unit bacterial strains, isolated from the Aegean Sea sponges, 86% belonged to phylum Proteobacteria. 82% of 102 bacterial strains, isolated from the sponges of the Sea of Marmara, were Proteobacteria. The study resulted in increasing data to understand antibacterial activity of the marine sponges regarding diversities of the sponge/sponge-associated bacteria according to their exposure local environmental conditions in the in the different marine areas.

## EFFECT OF TEMPERATURE ON BACTERIOPHAGE-MEDIATED BACTERIAL LYSIS EFFICIENCY

E.M. Ameh<sup>1</sup>, S. Tyrrel<sup>1</sup>, J.A. Harris<sup>1</sup>, A. Nocker<sup>1</sup>

<sup>1</sup>*Environmental Science and Technology, Cranfield University, Cranfield, United Kingdom*

### Background

Bacteriophages (phages) are viruses that specifically target bacteria. This property makes them useful agents for the control of pathogenic bacteria. Despite their great potential there is great uncertainty about the environmental parameters affecting phage-mediated lysis efficiency.

### Objectives

In this study, temperature was investigated as a key environmental factor.

### Methods

Three distinct phages specific for *E.coli* were isolated from a single brook water sample. Lysis efficiency was monitored using the double agar overlay method and optical absorbance measurements. Plaque sizes and numbers varied dramatically depending on whether phage-host mixtures were incubated at 20°C, 30°C or 37°C with bigger and more plaques being visible at lower temperatures. Interestingly plaque formation was invisible at the optimum temperature of the host (37°C). Plaque numbers and sizes were found to additionally depend on the temperature history of the bacterial host prior to mixing with the phage. This applied both to the growth temperature of the *E. coli* (with higher plaque numbers and sizes when cells were grown at lower temperature) and short term temperature exposure of fully grown cells. Exposure of *E. coli* to sublethal heat stress resulted in a phage resistant phenotype.

### Conclusions

These outcomes suggest that many phage-host interactions might be highly temperature-sensitive and phages seem to prefer host cells that were subjected to temperature conditions similar to the ones in the environment where the phages were isolated from. Phages-host interactions should be well characterized for their temperature preference and probably other environmental parameters prior to biocontrol and biosanitization applications to obtain optimal performance.

**CHANGES IN MEMBRANE SUBPROTEOME IN VIBRIO HARVEYI DURING THE ADOPTION OF VIABLE BUT NONCULTURABLE STATE BY EFFECT OF STARVATION AND VISIBLE LIGHT**

C. Parada<sup>1</sup>, Z. Bravo<sup>1</sup>, V.R. Kaberdin<sup>2</sup>, I. Barcina<sup>1</sup>, M. Orruño<sup>3</sup>, I. Arana<sup>1</sup>

<sup>1</sup>Inmunología Microbiología y Parasitología, Universidad del País Vasco UPV/EHU, Leioa, Spain

<sup>2</sup>Inmunología Microbiología y Parasitología, Ikerbasque Foundation / Universidad del País Vasco UPV/EHU, Leioa, Spain

<sup>3</sup>Inmunología Microbiología y Parasitología, Universidad del País Vasco UPV/EHU, Vitoria/Gasteiz, Spain

**Background**

*Vibrio harveyi* is a pathogen bacterium for a wide range of marine animals that can be isolated as a planktonic form. The behaviour of *Vibrio* spp. in natural environments is conditioned, among others, by temperature, light, salinity or nutrient scarcity.

**Objectives**

The aim of this study was to evaluate the physiological and proteomic changes that take place during *V. harveyi* survival in seawater under exposure to visible light.

**Methods**

For this purpose, populations of *V. harveyi* were maintained in sterile natural seawater at 20°C and under illumination for at least 21 days. Along experiments, total, active and culturable populations were enumerated and the outer membrane subproteome was analyzed.

**Conclusions**

Experimental conditions had a negative effect upon culturability of *V. harveyi*, inducing its entry into the viable but nonculturable (VBNC) state after 6-7 days of exposure, and provoked changes in the membrane subproteome composition.

Along the period of study, some outer membrane proteins remained unchanged (e.g. OmpW), while a set of proteins increased (i.e. lipoproteins and agglutination proteins) or became detectable under tested conditions (in this last group the transport-related proteins are especially relevant). So, all these proteins could be likely essential for sustaining the *V. harveyi* viability under stress conditions. In contrast, several proteins and especially those related to chemotaxis processes decreased or were undetected along survival.

Therefore, in response to starvation and exposition to visible light *V. harveyi* experiments an adaptation process which includes the entry into the VBNC state and the membrane subproteome reorganization.

## **BIOTECHNOLOGICAL POTENTIAL OF BACTERIA ISOLATED FROM MARINE SPONGES**

F. Araujo<sup>1</sup>, M. Machado Netto<sup>2</sup>

<sup>1</sup>Science, University of Rio de Janeiro State, Rio de Janeiro, Brazil

<sup>2</sup>General Microbiology, Federal University of Rio de Janeiro, Rio de Janeiro, Brazil

### **Background**

Marine sponge contains a great number of microorganisms present in their tissues. These ones perform symbiotic associations with their hosts, and are capable of producing secondary metabolites with various biotechnological properties.

### **Objectives**

Aiming to know more about microbial diversity present in aquatic environments and get bacterial species with potential application in biotechnology

### **Methods**

three species of marine sponges (*Hymeniacidon heliophila*, *Amphimedon viridis* and *Aplysina fulva*) were collected in two beaches of Rio de Janeiro, Brazil;. 38 bacterial isolates from these sponges were tested for the production of amylase, cellulase and caseinase using standard methodology.

### **Conclusions**

Of these, 19 showed enzymatic activity, 5 for amylase, 4 to cellulase and 16 for production of caseinase. Of all isolates tested only one colony was able to degrade the three substrates. The tests of biosurfactants' production, showed that 17 colonies were able to emulsify diesel. Our results show that the species of marine sponges studied are a great substrate for prospecting microorganisms with potential biotechnological applications

## **TOXICITY OF TERRESTRIAL CYANOBACTERIAL STRAINS ORIGINATED FROM FORESTS OF THE SERBIAN MOUNTAINS**

O. Babic<sup>1</sup>, D. Kovac<sup>1</sup>, J. Simeunovic<sup>1</sup>

<sup>1</sup>*Department of Biology and Ecology, Faculty of Sciences-University of Novi Sad, Novi Sad, Serbia*

### **Background**

As one of the oldest and highly diverse group of photosynthetic prokaryotic microorganisms, cyanobacteria are known as potent producers of various bioactive compounds with toxic effects.

### **Objectives**

Toxicity of five forest terrestrial, filamentous cyanobacterial strains belonging to *Oscillatoria* and *Nostoc* genera was investigated.

### **Methods**

The toxicity of intracellular extracts of cyanobacterial strains was tested in *Artemia salina* bioassay. The LC<sub>50</sub> values were recorded in all tested strains after 24 h (*Nostoc* genera) and 48 h (*Oscillatoria* genera). In the case of three *Oscillatoria* strains, a dose-dependent response in mortality that increased over time was observed after 24 h (1%-8%) and 48 h (72%-98%) of exposure. However, for the intracellular extracts of two strains, *Nostoc* T7 and *Nostoc* M2, toxicity was higher after exposure time of 24 h (70% and 97%) and 48 h (93% and 98%). According to the LC<sub>50</sub> values, cyanobacterial strain *Nostoc* M2 showed to be the most toxic strain with LC<sub>50</sub> value 0,59 mg/ml, followed by strain *Nostoc* T7 (LC<sub>50</sub>=1,25 mg/ml). Concerning *Oscillatoria* genera, the recorded LC<sub>50</sub> values were 3,49 mg/ml (*Oscillatoria* M1), 4,55 mg/ml (*Oscillatoria* M2) and 5,62 mg/ml (*Oscillatoria* T18).

### **Conclusions**

The results presented in this paper indicate that toxin production is strain-specific property, whereby intracellular content of three strains belonging to *Oscillatoria* genera was found to be less toxic to *A.salina* compared to the strains belonging to *Nostoc* genera. An additional objective which should be done is analysis and identification of toxic compounds present in the extracts responsible for observed toxicity.

**STUDIES ON PRODUCTION AND PURIFICATION OF BIOFLOCCULANT BY A BACTERIUM SPECIES ISOLATED FROM ADETI STREAM IN ILESA, OSUN STATE**

M. Bakare<sup>1</sup>, O. Bamigbade<sup>1</sup>, O. Omoboye<sup>1</sup>, I. Adewale<sup>1</sup>

<sup>1</sup>Microbiology, Obafemi Awolowo University, Ile-Ife, Nigeria

**Background**

Water clarification methods like flocculation, coagulation and sedimentation are often inappropriate because of the high cost and scarcity of chemical coagulants. This study was designed to provide a safe, cheaper and biodegradable flocculating agent.

**Objectives**

The objectives include isolation of bacterial isolate with flocculating properties from wastewaters and soil samples ; selection of a bacterium with the highest bioflocculant-producing potential; determination of the time course of bioflocculant production; and purification of the bioflocculant.

**Methods**

Wastewater and soil samples were collected from Ilesa and plated on yeast extract, peptone and glucose (YPG) agar. Plates were incubated at 25°C for 24 h. Colonies with mucoid appearance were selected. Pure isolates were stored on sterile YPG agar slants. Bioflocculant production was carried out by growing the organism in YPG medium at 25°C and centrifuged at 5000 rpm for 30 min. Flocculant activity was measured by using a suspension of kaolin clay. Time-course of bioflocculant production was determined by monitoring pH, cell growth and flocculating activity. Bioflocculant was purified by precipitation and gel-filtration chromatography.

**Conclusions**

The highest bioflocculant –producing isolate was identified as *Pseudomonas extremaustralis* ABL19. Maximum bioflocculant production was observed at the 66<sup>th</sup> h. The optimal bioflocculant activity of 94.4% was achieved with glucose and peptone in the medium. The molecular weight was estimated to be 60.8kDa. The bioflocculant was effective at 80°C and alkaline pH.

## **CHARACTERIZATION OF BIOACTIVE COMPOUNDS PRODUCED BY SOIL STREPTOMYCES SPP.**

Z. Bamzadeh<sup>1</sup>, M. Baserisaleh<sup>2</sup>, N. Bahador<sup>3</sup>, H. Hejazi<sup>4</sup>

<sup>1</sup>*Microbiology Department Basic Sciences Faculty Shahrekord Branch, Islamic Azad University, Shahrekord, Iran*

<sup>2</sup>*Microbiology Department Kazeroun Branch, Islamic Azad University, Kazeroun, Iran*

<sup>3</sup>*Microbiology Department Fars Science Research Branch, Islamic Azad University, Fars, Iran*

<sup>4</sup>*Skin Diseases and Leishmaniasis Research Center Department of Parasitology & Mycology School of Medicine, Isfahan University of Medical Sciences, Isfahan, Iran*

### **Background**

In general special properties of different geographical area could be considered as best sources of bioactive compounds, therefore investigation on these fields might be increased treatment of patients and reduce the rate of occurrence of antibiotic-resistant bacteria.

### **Objectives**

Major purpose of this study was isolation of antimicrobial metabolite producing *Streptomyces* spp. from soil samples and identification the structure of their antimicrobial metabolites.

### **Methods**

To perform the present study, 70 strains of *Streptomyces* spp. were isolated from soil samples and evaluated for producing of their antimicrobial products against some pathogenic microorganisms. Then, the antimicrobial producing strains were identified using phenotypic and genotypic methods. The best growth phase of production was determined and finally structures of antimicrobial compounds were assessed by <sup>13</sup>CNM, <sup>1</sup>HNMR and FT-IR methods. Regarding to determination of possible structures, all data obtained from <sup>13</sup>C NMR, <sup>1</sup>H NMR and FT-IR were analysis by NCBI PubChem Structure Search program.

### **Conclusions**

Out of 70 strains of indigenous *Streptomyces* spp., three strains had potent activity for production of antimicrobial metabolites. The isolates recognized as *Streptomyces griseus*, *Streptomyces phaeochromogenes* and *Streptomyces olivoviridis*. Metabolites

showed antimicrobial activity against *Escherichia coli*, *Salmonella typhi*, *klebsiella pneumonia*, *shigella dysenteriae*, *Bacillus cereus* and *Staphylococcus aureus*. The best growth phase for antimicrobial metabolite production was stationary phase, therefore based on these data all the metabolites recognized as secondary metabolites. Regarding to determination of possible structures, all data obtained from <sup>13</sup>C NMR, <sup>1</sup>H NMR and FT-IR were analysis by NCBI PubChem Structure Search program and resulted suggestion three possible structures of bioactive compounds.

## **ISOLATION AND CONSERVATION OF FLUORESCENT PSEUDOMONADS STRAINS FROM RHIZOSPHERE OF WHEAT**

A. Bapiri<sup>1</sup>, N. Khakipour<sup>1</sup>, A. Alipour Dehak<sup>2</sup>

<sup>1</sup>*Department of Soil Science, Savadkooh Branch Islamic Azad University, Savadkooh, Iran*

<sup>2</sup>*Technician of Soil Science, Savadkooh Branch Islamic Azad University, Savadkooh, Iran*

### **Background**

Plant Growth Promoting Rhizobacteria (PGPR) meets those of inhomogeneous rhizobacteria groups which are patented to increase and promote plant growth. Pseudomonas bacteria is one of the most important PGPR bacteria which can increase yield, growth and health of the plant through direct and indirect mechanisms.

### **Objectives**

In the present study, fluorescent pseudomonads isolated from Savadkooh's soils have been investigated with respect to their biochemical tests and physiological characteristics.

### **Methods**

In the first experiment, 30 soil samples were collected from the rooting zone of wheat at farmer's field in Savadkooh, Mazandaran province, Iran. The soil samples were serially diluted up to 6–7, plated on King's B (KB) agar medium and incubated at  $28 \pm 2^\circ\text{C}$  for 48 h. Distinct colonies showing fluorescence under UV light were picked and streaked on KB agar medium to check the purity. In the second experiment, for the identification of fluorescent pseudomonads, certain biochemical tests and physiological characteristics were conducted according to Bergey's Manual for determinative bacteriology.

### **Conclusions**

The results showed that 17 pseudomonas strains were detected based on yellow, green and blue pigments by viewing under UV light. Population of bacteria were  $2.71 \times 10^5 - 6.43 \times 10^7$  cell per gram of rhizosphere soil. Based on results of biochemical tests and physiological characteristics we were detected three species, *P. putida* > *P.*

*fluorescens* >> *P. aeruginosa*. Dominate species of fluorescent pseudomonads in rhizosphere of wheat was putida.

**SEASONAL DYNAMICS OF SOIL MICROBIAL COMMUNITIES UNDER  
DOMINANT UNDERSTORY VEGETATION IN SPRUCE SWAMP FOREST**

J. Barta<sup>1</sup>, A. Chronakova<sup>2</sup>, Z. Urbanova<sup>1</sup>, E. Kastovska<sup>1</sup>, K. Edwards<sup>1</sup>,  
H. Santruckova<sup>1</sup>, T. Picek<sup>1</sup>

<sup>1</sup>Department of Ecosystem Biology, University of South Bohemia, Ceske Budejovice,  
Czech Republic

<sup>2</sup>Institute of Soil Biology, Biology Centre AS CR v.v.i., Ceske Budejovice,  
Czech Republic

**Background**

Spruce swamp forests (SSF) are exceptional ecosystems which are considered to be important sources of greenhouse gases (GHG). Understorey vegetation dominates *Eriophorum vaginatum* and *Vaccinium myrtillus* which create patchy environment in SSF may mitigate GHG emissions. Presence of *Eriophorum* or *Vaccinium* can affect GHG emissions through the quality and quantity of its litter and root exudates. Their input directly affects microbial community and its decomposition capabilities.

**Objectives**

Our two main objectives were (i) to describe the seasonal dynamics of bacterial and archaeal communities in spruce swamp forests under the two dominant understorey vegetations (*Eriophorum* and *Vaccinium*) and (ii) to evaluate the effect of dominant vegetation on activity of soil enzymes.

**Methods**

To characterize microbial community we sequenced variable region V4 of 16SrDNA using Illumina MiSeq platform. OTU-picking and taxonomic assignment was performed using the QIIME 1.8.0 bioinformatics pipeline. Hydrolytic enzymes were analyzed by fluorometric method using 4-methylumbelliferone (MUB) labeled substrates.

**Conclusions**

Methanogenes (Methanomicrobia, Methanobacteria) dominated archaeal community followed by Thermoplasmata, MBGA and MCG (Fig. 1). Relative abundance of methanogens was significantly higher in *Spagnum* and *Eriophorum* than in *Vaccinium* sites. *Eriophorum* and *Vaccinium* sites were enriched by Proteobacteria in comparison to *Shagnum* sites (Fig. 2). On the other hand *Sphagnum* control site had higher relative amount of anaerobic bacteria (Firmicutes-Clostridia and Chloroflexi). Hydrolytic enzymes were dominated by phosphatase activity showing probably P

limitation which was highest on Sphagnum control site.

**ANAEROBIC OXIDATION OF METHANE IN SURFACE SEDIMENTS OF MARINE LAKE GREVELINGEN, NORTH SEA**

S. Bhattarai<sup>1</sup>, C. Cassarini<sup>1</sup>, M. Egger<sup>2</sup>, G. Gonzalez-Gil<sup>1</sup>, C.P. Slomp<sup>2</sup>, Y. Zhang<sup>3</sup>, P.N. Lens<sup>1</sup>

<sup>1</sup>*Department of Environmental Engineering and Water Technology, UNESCO-IHE, Delft, Netherlands*

<sup>2</sup>*Department of Earth Sciences - Geochemistry Faculty of Geosciences, Utrecht University, Utrecht, Netherlands*

<sup>3</sup>*State Key Laboratory of Microbial Metabolism, Shanghai JiaoTong University, Shanghai, China*

**Background**

Sulphate reducing anaerobic oxidation of methane (AOM) is a well-established phenomenon occurring in deep marine environments (~ below 100 m). However, relatively shallow anaerobic sediments containing methane and sulphate may harbour anaerobic methanotrophic microorganisms (ANME). Marine Lake Grevelingen is a former estuary with a water depth of ~ 40 m and salinity of 31 g/kg, which is separated from the North Sea by a dam. High rates of degradation and deposition of organic matter have resulted in methane rich anoxic sediments which combined with sulphate from sea water renders the site a potential niche for AOM.

**Objectives**

The main aim of this research was to explore whether AOM occurs in the surface sediment of Marine Lake Grevelingen.

**Methods**

Pore water chemical analysis, serum bottle incubation for activity tests, and microbial analysis by fluorescence *in situ* hybridisation (FISH) were conducted.

**Conclusions**

AOM was evident at depths of 5 to 15 cm in the sediment with a steep decline in CH<sub>4</sub> concentrations from ~5 mM at 20 cm depth to negligible at the sediment surface; concurrently, sulphide concentrations increased to 5 mM. *In vitro* incubations with CH<sub>4</sub> and SO<sub>4</sub><sup>2-</sup> showed sulphide production coupled to the consumption of sulphate at approximately equimolar ratios at 150 days. In contrast, sulphate and sulphide concentrations remained constant in biotic and abiotic control incubations. ANME and

archaeal cells were observed by FISH, which could be linked to AOM activity. Using three independent approaches, this study, for the first time provides evidence for the occurrence of AOM in sediments of Marine Lake Grevelingen.

**Environmental microbiology - 2**

**EXOPOLYSACCHARIDE PRODUCTION BY RHIZOBIUM ETLI STRAIN ZD13, A HEAVY METAL-RESISTANT SOIL ISOLATE**

N. Białas<sup>1</sup>, M. Żarska<sup>2</sup>, A. Czabańska<sup>3</sup>, K.A. Duda<sup>3</sup>, J. Radziejewska-Lebrecht<sup>1</sup>, O. Holst<sup>3</sup>

<sup>1</sup>Department of Microbiology, University of Silesia, Katowice, Poland

<sup>2</sup>Institute of Chemistry, University of Silesia, Katowice, Poland

<sup>3</sup>Division of Structural Biochemistry, Research Center Borstel, Borstel, Germany

**Background**

Exopolysaccharide (EPS) production functions as a protective strategy which favors the survival of microbes under unfavorable environmental conditions, e.g., heavy metal stress. Rhizobia are Gram-negative, rod-shaped bacteria known for EPS production. Some EPS, due to the presence of negatively charged functional groups, may act as heavy metal-binding agents.

**Objectives**

Studies on the EPS produced by *Rhizobium etli* strain ZD13 (RheZD13), an isolate from a postindustrial soil of the Upper Silesia (southern Poland).

**Methods**

RheZD13 was grown in 4 liters of a culture medium under aerobic conditions (120 h, 30°C, 120 rpm). Bacteria were pelleted by centrifugation (60 min, 4°C, 11806 x g) and the supernatant was sterile-filtered (Ø 0.22 µm) and treated with cold (-20°C) ethanol to precipitate the crude EPS. The latter was dialyzed and analyzed by GC and GC-MS.

**Conclusions**

4.627 g of RheZD13 EPS were obtained. The EPS contained glucose and galactose (in a molar ratio 3:1) and pyruvic acid that was 4,6-linked to galactose. The acidic nature and the resulting multiplicity of potential binding sites for positively charged particles suggested that RheZD13 EPS may act as a biosorbent for heavy metals.

**MICROBIOLOGICAL AND PHYSICAL-CHEMICAL CHARACTERIZATION OF  
SLUDGE GENERATED FROM WATER PURIFICATION PROCESS OF HUMAN  
WATER CONSUMPTION IN BRAZIL**

C. Bruschi<sup>1</sup>, T. Burgos<sup>2</sup>, J. Pelayo<sup>2</sup>

<sup>1</sup>CBQF, Universidade Catolica Portuguesa, Porto, Portugal

<sup>2</sup>Bacteriology, Universidade Estadual de Londrina, Londrina, Brazil

Water Treatment Plants (WTP) generate waste as residual decanters sludge due the production of potable water. The objective of this study was characterize microbiologically the sludge from three samples from the WTP of Londrina, Brazil, through microbiological indicators – as *Enterococcus* spp, sulphite-reducing *Clostridium* and pathogen *Salmonella* spp. The ‘multiple tubes’ technique was used to isolated bacteria. For physical-chemical analyzis parameters it was used Biochemical Oxygen Demand (BOD), Chemical Oxygen Demand (COD), turbidity, pH and apparent color (according to APHA, AWWA and WEF-2005). The results showed that in the sample 1, the most probable number (MPN) of microorganism per 100mL was 2,1x10<sup>4</sup> *Enterococcus* and 1,1x10<sup>5</sup> *Clostridium*; the sample 2 presented absence of *Enterococcus* and >2,4x10<sup>5</sup> *Clostridium*; and the sample 3, 1,0x10<sup>5</sup> *Enterococcus* and 2,4x10<sup>5</sup> *Clostridium*. *Salmonella* spp. was not detected in any sample analyzed. For sample 1, the BOD was 113,9 mg of oxygen/L, the COD of 6184,09 mg of oxygen/L, with turbidity of 24000 NTU, the pH 6,0 and apparent color of 100000 uH. For the sample 2, the BOD was 4334,59 mg of oxygen/L, the COD was not determined, with turbidity of 16800 NTU, the pH 6,38 and apparent color of 6000 uH. In sample 3, the BOD was 73,3 mg of oxygen/L, the COD was 2172,20 mg of oxygen/L, with turbidity of 4370 NTU, the pH 6,90 and apparent color of 16700 uH. The microbiological contamination was relevant, indicating high destructive potential for the environmental and healthy human population.

**MICROBIOLOGICAL AND PHYSICAL-CHEMICAL CHARACTERIZATION OF  
FLUSHING WATER FILTER FROM WATER TREATMENT PLANTS IN BRAZIL**

C. Bruschi<sup>1</sup>, T. Burgos<sup>2</sup>, J. Pelayo<sup>2</sup>

<sup>1</sup>CBQF, Universidade Catolica Portuguesa, Porto, Portugal

<sup>2</sup>Bacteriology, Universidade Estadual de Londrina, Londrina, Brazil

Water treatment plants (WTP) yields waste as decanters sludge and flushing water filter (FWF). The objective of this study was characterizing FWF for presence of *Enterococcus* spp., *Clostridium* sulphite-reducing and *Salmonella* spp.. For physical-chemical parameters Biochemical Oxygen Demand (BOD), Chemical Oxygen Demand (COD), turbidity, pH, apparent color, AWWA and WEF 2005 were used. The results showed in WTP-A (collection one), most probable number (MPN) of microorganism per 100mL was  $1,2 \times 10^2$  *Enterococcus* and  $>2,4 \times 10^3$  *Clostridium*; *Enterococcus* and  $1,1 \times 10^4$  *Clostridium*. BOD was 4,8 oxygen/L, COD 218,30mg oxygen/L, turbidity 754 NTU, pH 6,07 and apparent color 300 uH; In WTP-B, for collection 1, absence *Enterococcus*,  $7,0 \times 10^1$  *Clostridium*; BOD was 3,2 mg oxygen/L, COD 294,5 mg oxygen/L, turbidity 3990 NTU, pH 6,07 and apparent color 3000 uH. For collection 2, absence *Enterococcus* and  $4,3 \times 10^2$  *Clostridium*; BOD 2,43 mg oxygen/L, COD 1,3 mg oxygen/L, turbidity 881 NTU, pH 6,57 and apparent color 5500 uH; In WTP-B, for collection 2, absence *Enterococcus* and *Clostridium*; BOD 5,1 mg oxygen/L, COD 106,8 mg oxygen/L, turbidity 889 NTU, pH 6,78 and apparent color 4500 uH. For collection 3,  $3,9 \times 10^2$ ; BOD 11 mg oxygen/L, COD 628,83 mg oxygen/L, turbidity 1600 NTU, pH 6,98 and apparent color 54 uH;  $4,0 \times 10^1$  *Enterococcus* and  $4,0 \times 10^1$  *Clostridium*; BOD 3,7 mg oxygen/L, COD 170,9 mg oxygen/L, turbidity 190 NTU, pH 7,11 and apparent color 1100 uH. *Salmonella* spp. was not isolated. The microbiological contamination was relevant and high levels of physical-chemical parameters were detected in the flushing water filter, indicating destructive potential for the environment and population.

### **ENTERIC VIRUSES INACTIVATION BY GAMMA IRRADIATION**

A.I. Pimenta<sup>1</sup>, D. Guerreiro<sup>1</sup>, P.M.P. Santos<sup>1</sup>, A. Falcão<sup>1</sup>, F.M.A. Margaça<sup>1</sup>,  
S. Cabo Verde<sup>1</sup>

<sup>1</sup>C2TN, Centro de Ciencias e Tecnologias Nucleares, Bobadela, Portugal

#### **Background**

Enteric viruses, like norovirus and adenovirus are frequently detected in environmental systems and have been implicated in many outbreaks. Normally, the viruses exist in the environment and acquire certain capability to endure conventional treatment processes. Alternative disinfection methods must be developed.

#### **Objectives**

The main goal of this study was to investigate the inactivation of murine norovirus type 1 (MNV-1), as a Norovirus surrogate, and human adenovirus type 5 (AdV-5) by gamma irradiation.

#### **Methods**

Six different substrates: Phosphate buffer saline (PBS), demineralized water, tap water, fetal bovine serum (FBS) and aqueous solutions of 10% and 50% FBS, were inoculated with MNV-1 and AdV-5 and irradiated in a Co-60 source at several doses (1 up to 10 kGy). The inactivation of viral particles was tested by plaque assay using Raw 264.7 and A549 cells. The D<sub>10</sub> values were estimated for each virus and substrate.

#### **Conclusions**

A reduction on MNV and AdV titers of 4 log<sub>10</sub> PFU/ml was achieved after irradiation at 3 kGy on PBS and water suspensions. However, MNV and AdV were approximately 3 times more resistant to gamma irradiation when irradiated in FBS, and at a dose of 10 kGy it was detected the presence of infective viral particles. The observed D<sub>10</sub> values ranged between 0.76 kGy (water) and 3.22 kGy (10% FBS) for MNV; and between 0.87 kGy (PBS) and 2.94 kGy (FBS) for AdV. These results show that inactivation of MNV-1 and AdV-5 by gamma radiation strongly depends on the substrate where the viruses are inoculated.

**RECOVERY OF AN ACETATE-CONSUMING SULFATE REDUCING  
CONSORTIUM AT ACIDIC CONDITIONS**

N. Campos<sup>1</sup>, N.E. Lopez-Lozano<sup>1</sup>, A. Lopez-Cortes<sup>2</sup>, L.B. Celis<sup>1</sup>

<sup>1</sup>*Environmental Sciences Division,*

*Instituto Potosino de Investigacion Cientifica y Tecnologica, San Luis Potosi, Mexico*

<sup>2</sup>*Microbiology Division, Centro de Investigaciones Biológicas del Noreste,  
Baja California Sur, Mexico*

**Background**

Sulfidogenic reactors have been used to eliminate dissolved metals from industrial wastewaters, due to their possibility to obtain metal sulfides. Sulfate reducing bacteria (SRB) are responsible for the production of sulfide which reacts with dissolved metals, forming precipitates (metal sulfides). However, the major drawback of sulfidogenic reactors is that acetate cannot be degraded completely, reducing the reactor's efficiency, another problem is that metal containing wastewaters are usually acidic (pH 2-4).

**Objectives**

The objective of this work was to obtain a consortium from a natural acidic environment (an abandoned sulfur mine) able to work at low pH (<4) and produce sulfide from the complete oxidation of the substrate.

**Methods**

The enrichments were preformed from sediments cultured in anaerobic bottles (120 mL) and fed with acetate, glycerol, or lactate, and sulfate. The pH was initially 3 or 4, and we evaluated their capability to completely consume the substrate and produce sulfide. When the enrichment consumed the substrate and produced sulfide, we took 10 or 20 % (v/v) as an inoculum to develop a new enrichment of sulfate-reducing consortium.

**Conclusions**

Supernatant (only the liquid part) used as inoculum (10-20%) was not favorable for the growth of SRB. The slurry (combination of sediment and liquid) used as inoculum (20%) promoted the sulfate-reducing activity at acidic pH. Acetate, used as the sole electron donor, was not suitable for the SRB consortium. Complex electron donor, such as glycerol or lactate, was more suitable to obtain a sulfate-reducing consortium at low pH able to consume acetate and produce sulfide.

**FEMS-1954**

**Environmental microbiology - 2**

**BACTERIAL DIVERSITY AND DYNAMICS FROM START-UP TO STEADY CONDITIONS IN A FULL-SCALE MUNICIPAL SOLID WASTE (MSW) ANAEROBIC REACTOR BY 454 PYROSEQUENCING TECHNOLOGY.**

J. Cardinali-Rezende<sup>1</sup>, P. Rojas<sup>1</sup>, A. M. Amaral Nascimento<sup>2</sup>, E. Chartone-Souza<sup>2</sup>, J.L. Sanz<sup>1</sup>

<sup>1</sup>Molecular Biology, Institute of Biology - Universidad Autónoma de Madrid, Madrid, Spain

<sup>2</sup>General Biology, Biological Sciences, Belo Horizonte, Brazil

**Background**

Anaerobic digestion is an environmentally acceptable means of reducing and stabilizing organic fraction from MSW. Functioning and stability of an anaerobic reactor is directly related to the microbial community within it.

**Objectives**

The bacterial diversity of a full scale anaerobic reactor treating MSW from Madrid (Spain) was investigated using high-throughput 454 pyrosequencing technology.

**Methods**

The digested MSW samples were taken in two moments of the treatment: start-up phase and steady- state conditions. The bacterial 16S rRNA genes were amplified and sequenced using 454 pyrosequencing FLX machine.

**Conclusions**

118,392 bacterial 16S rDNA reads were yielded and after trimmed 35,981 (start-up phase) and 18,290 reads (steady conditions) were clustered into OTUs. Fifteen phyla were identified: *Bacteroidetes*, *Firmicutes*, *Actinobacteria*, *Proteobacteria*, *Chloroflexi*, SR1, *Synergistetes*, *Planctomycetes*, *Tenericutes*, *Deinococcus-Thermus*, *Acidobacteria*, *Chlorobi*, *Cyanobacteria* and *Gemmatimonadetes*. Shifts in the bacterial communities were observed and proteolytic bacteria dominated during all the process, being the major diversity identified in the steady-state condition of the reactor. Fermentative bacteria belonged to *Bacteroidetes* and *Firmicutes* phyla predominated, and a great number of reads were identified to genus level. *Proteiniphylum*, *Gallicola* and *Fastidiosipila* genera carried out most biodegradation processes during the MSW treatment. A great number of genera are involved in the

sugars and carbohydrates metabolisms, although its coverage is low. The high concentration of ammonium appears to be the reason for the prevalence of the proteolytic bacteria. The use of the next generation sequencer technology revealed a great diversity of rare organisms and increased our knowledge about the dynamics of bacterial communities in anaerobic MSW reactors.

**Environmental microbiology - 2**

**BACTERIAL DIVERSITY IN RHIZOSPHERE AND SOIL ON MINING WASTE IN THE ARID ENVIRONMENT OF THE SAHARA**

K. CHAFI<sup>1</sup>, B. CORNU<sup>2</sup>, S. FLAHAUT<sup>3</sup>, A. MOUSSAOUI<sup>1</sup>, C. VANDER WAUVEN<sup>2</sup>

<sup>1</sup>Biology, Tahiri Mohammed university, Béchar, Algeria

<sup>2</sup>Biology, Research institute Microbiological, Brussels, Belgium

<sup>3</sup>Biology, ULB, Brussels, Belgium

**Background**

Relatively few studies have been devoted to the microbial diversity of the Sahara. In this study, we have investigated an arid area located in south-west Algeria. In this area, spoil heaps of coal mine waste are colonized by a Saharo-Mediterranean vegetation dominated by *Caroxylon* sp.

**Objectives**

As part of an on-going study aiming to understand the role of micro-organisms in the adaptation of this plant to the site, we have studied its associated microflora.

**Methods**

The bacterial community was investigated by fingerprinting (RISA). The diversity was much higher in the *Caroxylon* rhizosphere than the surrounding soil, both on the waste heaps and in the desert soil. Libraries of 16S rRNA gene were obtained from rhizospheric and non rhizospheric soil-extracted DNA. Sequences from *Firmicutes* and *Actinobacteria* were abundant in all libraries. As expected from the fingerprints, the diversity was higher in the rhizosphere libraries, with 1.6 more phyla detected than in non rhizospheric soil.

**Conclusions**

Depending on the library, 25 to 65 % of the sequences had percentages of identity with known species below the 97% threshold. Potential new species are located in very diverse phyla. The most distant ones (less than 90% identity) belong to *Acidobacteria*, *Chloroflexi*, *Deltaproteobacteria*, *Cyanobacteria* and *Nitrospirae*. The results show that we have only begun to explore the diversity of soil bacteria in the arid environment of the Sahara.

**FEMS-0711**

**Environmental microbiology - 2**

**POTENTIAL OF CADMIUM RESISTANT AND BIPHENYL UTILIZING MARINE BACTERIA IN BIOREMEDIATION**

J. Chakraborty<sup>1</sup>, S. Das<sup>1</sup>

<sup>1</sup>Life Science, National Institute of Technology, Rourkela, India

**Background**

Utilization of aromatic compounds by marine microbial communities in nutrition and pollution stress has evolved several catabolic pathways for bioremediation. Of which, biphenyl and cadmium are highly toxic compounds having harmful effects on flora, fauna, and mankind.

**Objectives**

The main objective of this study was to find out the catabolic potential and pathway of marine bacteria in aerobic utilisation of biphenyl as sole carbon and energy source under toxic metal (cadmium) stress.

**Methods**

Two bacterial strains *Pseudomonas aeruginosa* (JP-11) and *Achromobacter xylosoxidans* (JP-22) were isolated from the coastal regions of Odisha, India, which could resist up to 1000 ppm and 630 ppm of cadmium respectively. They utilized 97.88 % and 89.6 % of biphenyl respectively. Combination of chromatographic and spectrophotometric techniques identified 2-Hydroxy-6-oxo-6-phenylhexa-2, 4-dienoate and benzopropanol as the intermediate product of biphenyl metabolism in JP-11 and JP-22 respectively. Biosurfactant production was observed which increased the bioavailability of this hydrophobic compound into the cells resulting in their effective removal from the environment. Of both the isolates, the partial structure of the biosurfactant produced by JP-11 was similar to that of rhamnolipid which showed an upregulation of rhamnolipid synthesis gene (*rhlAB*) with increased biphenyl concentration (upto 200 ppm).

**Conclusions**

Thus, these bacterial isolates can be efficiently utilized for bioremediation of the contaminated sites with toxic metal and organic pollutants.

Environmental microbiology - 2

## DIVERSITY OF OIL DEGRADING BACTERIA FROM GEOGRAPHICALLY DISTANT REGIONS

M.I. Charniauskaya<sup>1</sup>, M.A. Titok<sup>1</sup>

<sup>1</sup>Department of Microbiology, Belarusian State University, Minsk, Belarus

### Background

An investigation of oil degrading bacteria is significant for practical and fundamental reasons. The diversity of metabolic systems allows these microorganisms to utilize a wide spectrum of substrates and produce different biological active substances.

### Objectives

The main aim of this research was to characterize oil degrading bacterial strains isolated from different geographical regions (Belarus, Libya, Iraq, and Antarctic).

### Methods

Physiological, biochemical and molecular genetic methods were used.

### Conclusions

Taxonomy of 22 oil degrading bacterial strains was established. They were determined as *Rhodococcus pyridinivorans*, *R. opacus*, *R. erythropolis*, *Bacillus licheniformis*, *B. beijingsensis*, *B. flexus*, *Arthrobacter* sp., *Micrococcus* sp., *Enterobacter* sp., *Planococcus maitriensis*, *Acinetobacter radioresistens*, *Pseudomonas* sp., *P. stutzeri*, *Dietzia* sp., *Deinococcus* sp..

*R. pyridinivorans* 5Ap was shown to have the widest spectrum of utilizing substrates (it utilized 19 investigated organic substrates). Different strains were able to grow under extreme conditions. For example, *B. licheniformis* FD9 grew at 54 °C; *P. stutzeri*, *R. erythropolis*, *Arthrobacter* sp. - at 4 °C; *Enterobacter* sp. FD1 - pH=4, *B. beijingsensis* FD4 - pH=11, *P. maitriensis* FD3 – with sodium chloride concentration up to 7 %; *A. radioresistens* and *Deinococcus* sp. were UV-resistant.

It was shown the presence of naphthalene catabolic plasmids in the strains of *R. pyridinivorans* and *R. opacus*.

The ability of oil degrading bacteria to produce the surfactants was shown. The most effective production of surfactants was determined for *R. erythropolis* A29-k1 when it was cultivated on mineral medium with hexadecane. Lichenisyn biosynthesis genes were found in *B. licheniformis* FD9.

## **MICROBIOLOGICAL INVESTIGATION OF MUD VOLCANOES FROM EASTERN ROMANIA FLUIDS**

M. Mitache<sup>1</sup>, M. Popa<sup>2</sup>, I. Gheorghe<sup>2</sup>, A. Cotar<sup>3</sup>, C. Bleotu<sup>2</sup>, V. Lazar<sup>2</sup>, M. Chifiriuc<sup>4</sup>

<sup>1</sup>*Preclinical Medicine, University of Medicine Titu Maiorescu, Bucharest, Romania*

<sup>2</sup>*Life Environment and Earth Sciences,*

*Research Institute of the University of Bucharest, Bucharest, Romania*

<sup>3</sup>*Microbiology, INCDMI Cantacuzino, Bucharest, Romania*

<sup>4</sup>*Life Environment and Earth Sciences,*

*Research Institute of The University of Bucharest, Bucharest, Romania*

### **Background**

The largest areas of terrestrial mud volcanoes in Europe are located in the Carpathian Mountains in eastern Romania. Till now the few microbiological investigations were focused on the study of Archean communities implicated in methane- and hydrocarbon cycling.

### **Objectives**

The purpose of this study was to isolate, identify and characterize the pathogenic and resistance features of bacterial strains isolated from the bubbling fluids expelled from the mud volcanoes from Buzau in order to establish the contribution of these protected environments to the natural reservoirs of resistance and pathogenicity.

### **Methods**

All water samples (500 ml) were collected according to current ISO guidelines using sterile glass bottles, at a depth of approximately 30 cm and stored in cold bags at 4°C until analysis. The samples were diluted and analysed through the standardized membrane filtration method. The identification of aerobic strains obtained in pure culture was based on Gram staining, oxidase reaction and API galleries.

Simultaneously, the samples were processed for DNA extraction and molecular assays based on ribosomal DNA amplifications with general bacterial 16S rRNA primers. The isolated strains have been investigated for antibiotic susceptibility and for the production of cell-associated (adherence to inert and cellular substratum, biofilm development) and soluble, enzymatic (hemolysins, lecithinase, lipase, caseinase, gelatinase, amylase, esculin hydrolysis, DN-ase) virulence factors, using phenotypic (disk diffusion method, selective media for enzymatic factors production) and PCR-based methods.

## **Conclusions**

The virulence and resistance profiles of cultivable strains were very poor, suggesting the absence of any selective pressure agents in the investigated areas.

## **IDENTIFICATION AND CHARACTERIZATION OF GENES INVOLVED IN SIDEROPHORE PRODUCTION OF PANTOEA ANANATIS, THE CAUSATIVE BACTERIUM OF RICE SHEATH ROT**

J. Cho<sup>1</sup>, O. Choi<sup>1</sup>, J. Kim<sup>2</sup>

<sup>1</sup>*Division of Applied Life Science (BK21 Plus), Gyeongsang National University, Jinju, Korea*

<sup>2</sup>*Institute of Agriculture & Life Science, Gyeongsang National University, Jinju, Korea*

### **Background**

*Pantoea ananatis* is known to cause disease in maize, eucalyptus, onions, and rice. This bacterium is also known as an opportunistic human pathogen. *P. ananatis* PA13 is a rice grain and sheath rot bacterium, which produces an antibacterial compound.

### **Objectives**

In the present study, we have tried to identify and characterize genes involved in antibacterial activity in *P. ananatis* PA13.

### **Methods**

We performed a large-scale, *mariner* transposon-based genetic screening and gene replacement strategy based on homologous recombination. Antibacterial activity was monitored against *P. ananatis* HY02, onion center rot bacterium, and *Yersinia enterocolitica*.

### **Conclusions**

A number of proteins that involved in transcription, catalytic enzymes, siderophore transporting systems, and TonB-dependent transporter system were found to affect the antibacterial activity of strain PA13. These data indicate the iron uptake is a major factor of antibacterial activity in *P. ananatis* PA13. We focused then siderophore biosynthetic genes. *P. ananatis* has genes homologous to siderophore biosynthesis, aerobactin (*iucABCD*), alcaligin (*alcA*) and rhizobactin (*rhbF*). Single mutant of  $\Delta iucABC$  exhibited slight reduction of antibacterial activity, whereas  $\Delta alcA$  and  $\Delta rhbF$  showed normal antibacterial activity. This result led to generation of double and triple mutants of the genes. Mutants  $\Delta iucABC\Delta rhbF$  and  $\Delta iucABC\Delta alcA$  exhibited strong reduction in antibacterial activity, whereas mutant  $\Delta alcA\Delta rhbF$  showed normal antibacterial activity. These data indicate that siderophores play an important role in antibacterial activity of *P. ananatis* PA13. This work will give novel insights into iron

uptake regulation and contribute to a better understanding of how these genes function to regulate iron uptakes.

## **HYDROGEN PRODUCTION AND VFA ACCUMULATION IN A CONTINUOUS STIRRED TANK REACTOR USING MOLASSES WASTEWATER AS FEEDSTOCK**

K. Cho<sup>1</sup>, J. Yun<sup>1</sup>, T. Kim<sup>2</sup>

<sup>1</sup>*Department of Environmental Science and Engineering, Ewha Womans University, Seoul, Korea*

<sup>2</sup>*Ecological Information Management, National Institute of Ecology, Choongnam, Korea*

### **Background**

Molasses wastewater as a sugar-rich waste is a liquid by-product generated in large amount from food industries. Molasses wastewater is one of promising feedstock for bioenergy production because it has high strength of organics and relatively high bioavailability.

### **Objectives**

For bioenergy production and wastewater treatment simultaneously, two-stage fermentation processes employing hydrogenesis and methanogenesis have been developed. Hydrogenesis has advantage of volatile fatty acids (VFAs) as main byproducts as well as hydrogen, and VFA production is necessary to stabilize the waste stream in the secondary stage for methane production. Hydrogen production and VFA production was characterized in a continuous stirred tank reactor (CSTR) fed molasses wastewater as feedstock.

### **Methods**

The CSTR reactor achieved a stable performance at an organic loading rate from 20.3 to 36.1 g-COD·L<sup>-1</sup>·d<sup>-1</sup>. Average gas production rate was 1.2 L/d with a hydrogen concentration of 33%. The maximum hydrogen production rate was 1.02 L-H<sub>2</sub>·L<sup>-1</sup>·d<sup>-1</sup> at 31.0 g-COD·L<sup>-1</sup>·d<sup>-1</sup>. The abundant VFAs were butyric acid (50%) and acetic acid (38%). Total VFA production kept at around 7,135 mg/L level during operation period. Active microbial community was analyzed using rRNA-based massively parallel sequencing technique. Clostridiales, *Lactobacillus* and *Clostridium* were relatively abundant in the CSTR reactor. It has been reported that appearance of *Clostridium* species was in accordance with increase of butyrate and acetate concentration. *Lactobacillus* species has been known to be involved in anaerobic lactate degradation to acetate.

### **Conclusions**

VFAs produced in the CSTR reactor can be utilized as substrates for methane production in downstream processes.

**Environmental microbiology - 2**

**STARVATION EFFECT ON METHANE PRODUCTION IN AN UPFLOW ANAEROBIC SLUDGE BLANKET REACTOR**

H. Choi<sup>1</sup>, J. Yun<sup>1</sup>, K. Cho<sup>1</sup>

<sup>1</sup>DEPT. Environmental Science and Engineering, Ewha Womans University, Seoul, Korea

**Background**

Biohydrogen and biomethane can be produced in Upflow Anaerobic Sludge Blanket (UASB) reactors treating high strength wastewaters such as molasses wastewater and distillery wastewater.

**Objectives**

Even though many researches have been reported on the performance of UASB reactors and their microbial properties, there is little information about the effect of starvation on the UASB performance. In this study, the effect of starvation on methane production was characterized in an UASB reactor.

**Methods**

Anaerobic digested sludge was used as an inoculum source, and the effluent (10,000 mg-COD/L) from an hydrogen-producing UASB reactor treating molasses wastewater was used as influent wastewater for the methane-producing UASB reactor. The UASB reactor was operated for 18 days at hydraulic retention time of 3 d. After confirming the UASB performance reached at steady-state, the UASB was maintained at starvation condition for 14 d or 30 d. After starvation period, the UASB was re-operated by feeding the influent without re-inoculation, and COD removal and methane production were compared with their performance at steady-state (COD removal and methane production rate were 98% and  $0.91 \text{ L-CH}_4 \text{ L}^{-1} \text{ d}^{-1}$ , respectively).

**Conclusions**

After 3-days of 14 d-starvation, COD removal and methane production rate were 87% and  $1.51 \text{ L-CH}_4 \text{ L}^{-1} \text{ d}^{-1}$ , respectively. The UASB performance improved speedy, and the UASB performance could be recovered by 15-days operation after restarting. However just after 30 d of starvation, no COD removal and methane product was observed, and over 27-days operation was necessary to recovery the UASB performance. These findings can be used to plan the operation strategy of methane-producing UASB reactors.

## **APPLICATION OF BIOLOG PHENOTYPING MICROARRAYS FOR ASSESSING THE FUNCTIONAL DIVERSITY OF ENVIRONMENTAL STRAINS OF BACILLUS**

*I. Biedron<sup>1</sup>, G. Plaza<sup>2</sup>, K. Paraszkievicz<sup>3</sup>, J. Chojniak<sup>2</sup>*

<sup>1</sup>*Microbiology Team, Wrocław University of Technology, Wrocław, Poland*

<sup>2</sup>*Microbiology Team, Institute for Ecology of Industrial Areas, Katowice, Poland*

<sup>3</sup>*Industrial Microbiology and Biotechnology, University of Łódź, Łódź, Poland*

### **Background**

The ability to link genotypes to corresponding phenotypes is of interest in biotechnological manipulation of metabolic pathways. In order to assess a rapid functional and phenotypic profiling under different metabolic conditions, a high-throughput approach has been developed by BIOLOG Inc. (Hayward, CA): the Phenotype Microarray (PM) technology.

### **Objectives**

The objective of the study was to determine phenotypic changes in environmental strains of *Bacillus* by Phenotyping MicroArrays.

### **Methods**

The four *Bacillus* strains were tested on PM 96-well plates (PM01-02 carbon sources, PM03 nitrogen sources, PM04 phosphorus and sulfur sources, PM09 with osmolytes, PM10 with another pH, PM11-13 with various antibiotics). *Bacillus subtilis* ATCC as reference strain was used to determine the differences between strains. Data were analyzed with Omnilog-PM software. The software suite called 'DuctApe' which analyzes and links together both the genomic and the phenomic data and suggests genetic explanations of metabolic phenotypes was also used.

### **Conclusions**

The environmental isolates as compared to the reference strain were found to be the most metabolically versatile strains, either by looking at the number of 'more active' metabolic features or by the proportion of active compounds for each category. The strains showed higher proportion of active compounds for carbon and nitrogen sources and in the resistance to chemical agents. The DuctApe software is good tool for the visualization of PM data, the exploration of both the genomic information and the phenotypic expression of *Bacillus* spp. tested. Phenotypic profiling is an essential step for understanding genotype differences for environmental microorganisms of interest in contaminant remediation, biofuels production, and climate change.

**THE STRUCTURAL AND FUNCTIONAL BIODIVERSITY OF MICROORGANISMS  
IN SOIL UNDER EX SITU AIDED PHYTOSTABILIZATION**

D. Wasilkowski<sup>1</sup>, J. Chojniak<sup>2</sup>, G. Płaza<sup>2</sup>, A. Mroziak<sup>1</sup>

<sup>1</sup>Biochemistry, University of Silesia, Katowice, Poland

<sup>2</sup>Environmental Microbiology, Institute for Ecology of Industrial Areas, Katowice, Poland

**Background**

The high toxicity of heavy metals causes the need to remove them from the contaminated soil using minimally invasive remediation solutions. One of them seems to be aided phytostabilisation.

**Objectives**

The aim of this project was to investigate the impact of organic by-products as heavy metals stabilizers in soil on the biodiversity of microorganisms under *ex situ* aided phytostabilisation.

**Methods**

Green waste compost and pulp from the processing of grain were introduced into highly contaminated with Zn, Pb and Cd soil. As a phytostabilizer grass *Festuca arundinacea* was used. After 18 weeks the activity of enzymes: dehydrogenases, phosphatases and urease as well as the structural and functional biodiversity of microorganisms were tested. The biomass of grass after crop was also analysed.

**Conclusions**

The activity of enzymes in soil supplemented with grain was significantly higher in comparison with their activity in soil amended with compost. Simultaneously, the addition of grain into soil caused the highest increase the metabolic activity and biodiversity of microorganisms in comparison with soil amended with green compost. Additionally, after plant cutting the grass achieved the highest biomass in soil with grain.

## **REMOVAL OF HEXAVALENT CHROMIUM BY OCHROBACTRUM SP. CUST210-1 AND CHROMATE REDUCTASE**

C.Y. Chen<sup>1</sup>, M.C. Hsieh<sup>2</sup>, C.C. Li<sup>2</sup>, Y.T. Chen<sup>2</sup>, Y.C. Chung<sup>2</sup>

<sup>1</sup>Department of Tourism and Leisure, Hsing Wu College, New Taipei city, Taiwan

<sup>2</sup>Department of Biological Science and Technology,  
China University of Science and Technology, Taipei city, Taiwan

### **Background**

Chromium is extensively used in resistant alloys, electroplating, dye productions and leather tanneries. Hexavalent chromium (Cr<sup>6+</sup>) is a toxic, mutagenic and carcinogenic chemical. Physicochemical processes have been applied in Cr<sup>6+</sup> treatment, however, their setup and operating costs are high for large-scale treatment. Based on this consideration, biotechnology is a potential alternative.

### **Objectives**

In this study, we would like to reveal the characteristics of *Ochrobactrum* sp. CUST210-1 and its crude chromate reductase in removing Cr(VI).

### **Methods**

We isolated chromium-resistant bacterium from leather industry wastewater by chemostat. Its chromate reductase was purified and further identified by SDS-PAGE. Characteristics of bacterial cell and chromate reductase for Cr(VI) removal were evaluated.

### **Conclusions**

A facultative *Ochrobactrum* sp. CUST210-1 was isolated and it achieved high removal efficiency at relatively low Cr(VI) concentration (<350 mg/L) under the aerobic condition. Cu<sup>2+</sup>, Zn<sup>2+</sup>, Ni<sup>2+</sup>, SO<sub>4</sub><sup>2-</sup> and Cl<sup>-</sup> with 10-150 mg/L did not affect Cr(VI) removal by CUST210-1. Thus, the cell technique could be applied in treating chromium-containing wastewater (e.g. leather industry wastewater). By SDS-PAGE analysis, we confirmed that crude chromate reductase was successfully isolated. NADH rather than carbohydrate was optimal e<sup>-</sup> donors for the activity of chromate reductase. Thus, immobilized enzyme technique could be applied in treating chromium-containing wastewater with low concentrations of organic compounds (e.g. electroplating wastewater). To our knowledge, this is the first report to demonstrate the application range by bacterial cell or immobilized enzyme in removing Cr(VI).

**INVESTIGATION OF METABOLICALLY ACTIVE BACTERIA LEVELS AROUND  
GÖKÇEADA ISLAND (THE NORTHERN PART OF AEGEAN SEA), TURKEY**

**P. CİFTÇİ TURETKEN<sup>1</sup>, G. ALTUĞ<sup>1</sup>**

*<sup>1</sup>Marine Biology, Istanbul University Faculty of Fisheries, ISTANBUL, Turkey*

**Background**

Determination of the metabolically active bacteria level in the studied area is essential in terms of describe of bacteria that contribute to the ecological in aquatic ecosystems. Metabolically active bacteria have a well-developed polysaccharide capsule whereas inactive bacteria rapidly release the capsule (the term "capsulated bacteria was used in reference to "capsule bearing bacteria").

**Objectives**

The aim of this study was to investigate total and metabolically active bacteria levels at the surface sea water samples taken the coastal and off shore areas which have chosen around Gökçeada Island, northern part of Aegean Sea (Fig.1).

Fig. 1. Sampling area

## Methods

Sea water samples were taken 19 stations around Gökçeada Island (northern part of Aegean Sea) seasonally for the autumn, winter, spring as monthly for the summer in 12 times in total between March 2012 - November 2013. The frequency of the metabolically active bacteria was determined with modified staining technique comparing the number of the intact cells to the total (live and dead bacterial cells) number of bacteria (Plante and Shriwer, 1998; Stodereger and Herndl., 2001).

## **Conclusions**

The highest metabolically active bacteria percentage was determined to be 33.12% in the seawater samples which were taken from Aydıncık Bay in 2012 summer and the metabolically active bacteria levels in coastal station was found higher than the off-shore stations.

This work was supported by Research Fund of the Istanbul University as a PhD thesis project (Project No: 17653).

## **DEGRADATION OF NAPROXEN BY A SELECTED FUNGAL STRAIN**

Y.D. Aracagök<sup>1</sup>, N. Cihangir<sup>1</sup>, H. Göker<sup>2</sup>

<sup>1</sup>Department of Biology, Hacettepe University, ANKARA, Turkey

<sup>2</sup>Department of Pharmaceutical Chemistry, Ankara University, ANKARA, Turkey

### **Background**

Pharmaceuticals are widely used for treating human and animal diseases. These active compounds and their metabolites can enter aquatic environments via urine, feces, discharge from production facilities and hospital wastes (Kosjek et al. 2005). Naproxen and its sodium salt are members of the  $\alpha$ -arylpropionic acid group of non-steroidal anti-inflammatory drugs. Due to excessive usage of naproxen, this drug has been detected in aquatic environments and even in drinking water (Marco-Urrea et al. 2010).

### **Objectives**

The principal aim of this research was assessment of naproxen degradation capabilities of four fungal strains, include two white-rot fungi (*Phanerochaete chrysosporium*, *Funalia trogii*), yeast *Yarrowia lipolytica*, filamentous fungus *Aspergillus niger* and identification of byproducts.

### **Methods**

The LC/MS spectra were taken on a Waters Micromass ZQ connected with Waters Alliance HPLC, using ESI (-) method, with C-18 column. For the structural elucidation of isolated metabolites, low resolution LC-MS and NMR spectroscopy have been used. <sup>1</sup>H (400 MHz) was recorded employing a VARIAN MERCURY 400 MHz FT spectrometer.

### **Conclusions**

*Aspergillus niger* found to the most efficient strain with %98 degradation rate. Two main byproducts of degradation, O-desmethylnaproxen and 7-hydroxynaproxen were identify using LC/MS and <sup>1</sup>H-NMR.

<sup>2</sup>Center of Soil and Environmental Resources, Agronomic Institute/IAC, Campinas, Brazil

<sup>3</sup>Department of Soil Science, University of São Paulo/ESALQ, Piracicaba, Brazil

<sup>4</sup>Agronomic Institute/IAC, Center of Soil and Environmental Resources, Campinas, Brazil

### Background

The plant growth-promotion bacteria improve nutrient uptake, reduce fertilization cost and also minimize the environmental pollution by decreasing nitrogen leaching. However, there is not enough data about plant growth-promotion bacteria and grasses interaction, especially with endophyte bacteria.

### Objectives

The aim of this work was evaluate the possible benefits of three diazotrophic endophytic bacteria about the role in the nitrogen metabolism, ability to synthesize plant hormones and the influence of different N level on wheat plant.

### Methods

Wheat plants were fertilized with three nitrogen levels (no-fertilizer, half recommended N-fertilizer and full recommended N-fertilizer) and treated with different *nif* H<sup>+</sup>, endophytic bacteria: IAC-AT-8 (*Azospirillum brasilense*), IAC-HT-11 (*Achromobacter insolitus*) and IAC-HT-12 (*Zoogloea ramigera*). The enzymes nitrate reductase, glutamine synthetase and chlorophyll content analyses were analyzed as well as the IAA production by the strains. Before the harvest the nitrogen and the growth promotion were also evaluated.

### Conclusions

All the three bacteria were able to modify the nitrate reductase and the glutamine synthetase activities and improve the chlorophyll content, and promote the root and shoot weight. The strains also produced IAA in pure cells culture. The N content and the N-use efficiency index were dependent on the endophytic bacteria strain and on the plant tissue assessed. In general, the performance of the above parameters was strongly affected by the nitrogen rate. The different responses suggest that the successful colonization and the growth promotion are achieved by distinct mechanisms.

## **ANTIBIOTICS PROMOTE AGGREGATION WITHIN AQUATIC BACTERIAL COMMUNITIES**

M. Coci<sup>1</sup>, G. Corno<sup>2</sup>, M. Giardina<sup>3</sup>, S. Plechuk<sup>3</sup>, F. Campanile<sup>3</sup>, S. Stefani<sup>3</sup>

<sup>1</sup>Microbial Ecology, MICROB&CO, Catania, Italy

<sup>2</sup>Institute of Ecosystem Study, CNR, Verbania, Italy

<sup>3</sup>Bio-Medical Sciences, University of Catania, Catania, Italy

### **Background**

The release of antibiotics (AB) into the environment poses several threats for human. Knowledge on the impact of AB on natural bacterial communities is missing both in terms of spread and evolution of resistance mechanisms, and of modifications of natural community composition and productivity.

### **Objectives**

We performed a chemostat-based experiment with 4 coexisting bacterial strains mimicking a freshwater bacterial community to study their response to antibiotics in low and high doses.

### **Methods**

Bacterial abundance rapidly decreased by 75% in the presence of AB, independently of their concentration, and remained constant until the end of the experiment. The bacterial community was mainly dominated by *Aeromonas hydrophila* and *Brevundimonas intermedia* while the other two strains, *Micrococcus luteus* and *Rhodococcus* sp. never exceed 10%. Interestingly, the bacterial strains, which were isolated at the end of the experiment, were not AB-resistant; in addition reassembled communities composed of the 4 strains, isolated from treatments under AB stress, significantly raised their performance (growth rate, abundance) in the presence of AB compared to the communities reassembled with strains isolated from the treatment without AB. By investigating the phenotypic adaptations of the communities subjected to the different treatments, we found that the presence of AB significantly increased co-aggregation by 5-6 fold.

### **Conclusions**

These results represent the first observation of co-aggregation as a successful strategy of AB resistance based on phenotype in aquatic bacterial communities, and can represent a fundamental step in the understanding of the effects of AB in aquatic ecosystems.

**ISOLATION AND CHARACTERIZATION OF THERMOTOLERANT PETROLEUM-  
OXIDIZING BACTERIA FROM GEOGRAPHICALLY REMOTE REGIONS**

Y. Delegan<sup>1</sup>, A. Vetrova<sup>1</sup>, V. Akimov<sup>2</sup>, M. Titok<sup>3</sup>, A. Filonov<sup>1</sup>

<sup>1</sup>Laboratory of Plasmid Biology,

G.K. Skryabin Institute of Biochemistry and Physiology of Microorganisms,  
Pushchino, Russia

<sup>2</sup>All-Russian collection of microorganisms,

G.K. Skryabin Institute of Biochemistry and Physiology of Microorganisms,  
Pushchino, Russia

<sup>3</sup>Microbiology department, Belarusian State University, Minsk, Belarus

**Background**

Bioremediation of oil-polluted ecosystems in the hot climate regions can be performed by microbial consortia of thermotolerant bacteria.

**Objectives**

The objective of our work was to isolate thermotolerant bacteria from soil and water samples, physiological and biochemical analysis and taxonomic characterization of the bacteria.

**Methods**

In the work we used such methods as bacterial cultivation, DNA isolation, PCR, electrophoresis in agarose gel, direct sequencing, phylogenetic analysis, IR-spectroscopy.

**Conclusions**

Among 85 petroleum-oxidizing bacteria isolated from soil and water samples of Russia, Kazakhstan and Antarctica 15 thermotolerant gram-positive strains have been found which can utilize petroleum and particular hydrocarbons at 45°C and higher. The isolates were identified as the members of genera *Gordonia*, *Paenibacillus* and *Rhodococcus* and were closely related to known species of those genera. The *alkB* gene (encodes for alkane 1-monooxygenase) has been determined in all *Gordonia* isolates. Most thermotolerant isolates of genera *Gordonia*, *Paenibacillus* and *Rhodococcus* utilize petroleum in salt-enriched media.

The strains *Rhodococcus* sp. 5Ap, *Rhodococcus* sp. Par7 and *Gordonia* sp. 1D were the most effective thermotolerant petroleum-oxidizing bacteria at 45°C – 27%, 14% and 20% of petroleum, respectively. At the temperature 24°C the most effective petroleum-oxidizing strain was *Gordonia* sp. 1D – up to 59% of petroleum.

**ADAPTATION OF ARTHROSPIRA SP. PCC 8005 TO NITROGEN STARVATION:  
UNEXPECTED EXPRESSION OF HETEROCYST-LIKE PROTEINS**

F. Deschoenmaeker<sup>1</sup>, M. Demeuldre<sup>2</sup>, N. Leys<sup>3</sup>, R. Wattiez<sup>1</sup>

<sup>1</sup>Proteomic and Microbiology, University of Mons, Mons, Belgium

<sup>2</sup>Biology of Marine Organisms and Biomimetics, University of Mons, Mons, Belgium

<sup>3</sup>Microbiology, SCK-CEN, Mol, Belgium

**Background**

Among the most spread microorganisms on Earth, cyanobacteria play a dominant role in nitrogen and carbon cycles. The main limiting factor in cyanobacterial growth results from essential nutrients deprivation (e.g., nitrogen starvation). To deal with that, cyanobacteria develop survival strategies, including morphological and metabolic changes.

**Objectives**

This study aims to investigate the morphological and metabolic changes within *Arthrospira* sp. PCC 8005 under N starvation.

**Methods**

In order to characterize the biological response of this strain, a multidisciplinary investigation was carried out (*i.e.*, proteomic, electronic microscopy, intracellular compounds assay,...).

**Conclusions**

*Arthrospira* sp. PCC 8005 underwent to metabolic reprogrammings of C and N metabolisms. Proteomic investigations suggested a degradation of the phycobilisomes, cyanophycine and potential endogenous N sources (e.g., nitrile, urea, cyanates & formamide) to counteract the lack of N in the medium. As N metabolism is regulated thanks to N-to-C ratio, N starvation results in C over-excess, which was stored as glycogen as indicated by proteomic and transmission electronic microscopy investigations. TEM confirmed proteomic results as shown in the decreased of thylakoids, cyanophycin, and in glycogen granules accumulation. *Arthrospira* sp. PCC 8005 exhibited a survival capacity during long-N starvation, likely by maintaining a basic activity in cells named HFN<sup>-</sup>, probably to sustain colonies viability. Interestingly, proteomic results showed an increased of heterocyst-like proteins (HetR & HglK), while the colonies are non-heterocystous. In order to characterize the role of these heterocyst-like proteins during N starvation in our strain, we carried out immunolocalization of HetR, and studied its potential protein partners by co-immunoprecipitation.

**ANALYSIS OF EXTRACYTOPLASMIC FUNCTION SIGMA FACTORS IN THE  
PLANT GROWTH-PROMOTING RHIZOBACTERIA BURKHOLDERIA  
PHYTOFIRMANS PSJN**

R. Donoso<sup>1</sup>, T. Ledger<sup>1</sup>, B. Gonzalez<sup>1</sup>

<sup>1</sup>*Ingeniería y Ciencias, Universidad Adolfo Ibáñez, Santiago, Chile*

**Background**

Nutrient availability makes plant internal tissues and rhizosphere attractive spaces for microbial colonization. However, bacteria interacting with plants need to adapt to constant environmental changes, reacting to fluctuations in their immediate surroundings through global gene regulation. Sigma factors are dissociable subunits of RNA polymerase that regulate gene transcription initiation by recognition of specific promoter sequences. Their total number in the genome of a specific bacterial strain is usually determined both by its lifestyle and its genomic size. The extracytoplasmic function sigma factors (ECFsf) are the largest and more diverse group of these factors (classified into 43 subgroups), but little is known about their functions, although they are predominant in environmental and plant associated bacteria, which makes them interesting candidates for global gene regulation during plant colonization.

**Objectives**

The aim of this study was to inactivate and to characterize ECFsf present in the plant growth-promoting rhizobacteria *Burkholderia phytofirmans* PsJN.

**Methods**

This strain contains 18 ECFsf, which were inactivated by insertional mutagenesis.

**Conclusions**

Results suggested that at least one ECFsf could be related with growth and general metabolic processes in strain PsJN, meanwhile others ECFsf may be specifically involved in oxidative stress tolerance and biofilm formation, processes related to plant colonization by bacteria. In general, the results support a possible role of ECFsf in plant bacteria interactions at the level of the rhizosphere.

## **MELANIN SYNTHESIS BY BACILLUS WEIHENSTEPHANENSIS STRAINS ISOLATED FROM SOIL IN NORTHEASTERN POLAND**

J.M. Drewnowska<sup>1</sup>, M. Zambrzycka<sup>1</sup>, I. Swiecicka<sup>1</sup>

<sup>1</sup>Department of Microbiology, University of Białystok, Białystok, Poland

### **Background**

Melanin is known for protecting living organisms from harmful physical and chemical factors, however, its synthesis is rarely observed among *Bacillus cereus sensu lato*. So far, only two melanin-positive wild strains, *B. thuringiensis* subsp. *dendrolimus* [1] and *B. thuringiensis* subsp. *kurstaki* [2], have been described, but melanin production by *B. weihenstephanensis* has not been reported yet.

### **Objectives**

*B. weihenstephanensis* isolates originated from soil in Northeastern Poland were investigated in order to assess physicochemical properties of a blackish-brown pigment they produced and the mechanism of its synthesis in relation to their genotypic and phenotypic characteristics.

### **Methods**

Phenotypic and genotypic investigation of the melanin producers were done using API system, Multi-locus Sequence Typing, 16S rRNA sequencing, and Pulsed-Field Gel Electrophoresis. Fourier transform infrared spectroscopy we used to compare produced pigment with commercial melanin. The mechanism of the pigment production was assessed by biochemical tests and the whole genome sequencing of one *B. weihenstephanensis* strain.

### **Conclusions**

For the first time, we report that psychrotolerant *B. weihenstephanensis* can produce melanin pigment, which is probably associated with laccase activity. These environmental isolates are closely related to the *B. weihenstephanensis* DSMZ 11821 reference strains. The ability of melanin synthesis by soil *B. weihenstephanensis* strains seems to be a local adaptation to a specific niche.

### **Background**

In public buildings and facilities, in areas with high humidity and specific climatic conditions microbiological corrosion is an important factor affecting the reliability and durability of structures made of metal, concrete and reinforced concrete. Therefore, the problem of potential protection of building materials and structures is very complex and actual.

### **Objectives**

Estimation of the degree of contamination of reinforced concrete structures of Almaty subway by corrosive dangerous microflora.

### **Methods**

Isolation of corrosive dangerous microorganisms was performed by seeding selected water samples and swabs of concrete materials on selective media.

### **Conclusions**

7 stations of Almaty subway were examined in spring 2014. 31 samples were selected, including 5 water samples and 26 swabs from different visually damaged surfaces of reinforced concrete structures. Studies have shown that pH of the water samples and scrapings were neutral or alkaline. Heterotrophic bacteria, filamentous fungi and denitrifying microorganisms were found in almost all samples. Their number was high enough. This is an alarming fact, because of their intensive development can contribute to a change in environmental conditions that are favorable for the development of thione and sulfate-reducing bacteria, which are corrosive dangerous microorganisms. Further, these group of microorganisms may also participate in the destruction of the concrete.

Thione and sulfate-reducing bacteria were detected in small amounts. However, their presence shows that they can grow intensively in creating the favorable conditions and thereby contribute to the development of corrosion processes in reinforced concrete structures.

## **THE DIVERSITY OF MICROBIAL COMMUNITIES AT ACIDIC MINE WATER OUTLETS IS DRIVEN BY STOCHASTIC PROCESSES**

L. Falteisek<sup>1</sup>, V. Duchoslav<sup>2</sup>, I. Cepicka<sup>1</sup>

<sup>1</sup>Zoology, Charles University in Prague Faculty of Science, Prague 2, Czech Republic

<sup>2</sup>Ecology, Charles University in Prague Faculty of Science, Prague 2, Czech Republic

### **Background**

Explanation how the vast microbial diversity with multiple concurrent organisms may persist at a single site is still elusive for microbial ecology. One of plausible hypotheses is that a large number of spatially separated microcommunities exist within each complex habitat. Thus, each real assembly consists of a small and largely random selection of organisms from the total observed diversity.

### **Objectives**

One of plausible ways to test these hypotheses is to compare microbial communities from homogeneous microhabitats that exist in multiple physically separated copies at a single site. We selected ferruginous stalactites growing in large groups at acidic mine drainage outlets as a model of such microhabitats.

### **Methods**

Two groups of microbial stalactites growing at a single acidic mine drainage outlet and six stalactites from other sites were sampled. Prokaryotic 16S rDNA was amplified using universal primers and microbial diversity was characterized by tRFLP and amplicon pyrosequencing.

### **Conclusions**

Both methods showed that simple and homogeneous microbial communities inhabited all stalactites, but species-level OTU composition substantially differed even between adjacent stalactites. Although the sampling sites influenced composition of microbial communities, all OTUs including the most abundant ones unpredictably alternated in all samples. As a result, a large portion of communities clustered independently of locality or other variables by both phylogenetic beta diversity and OTU abundance metrics. Thus, each community probably contains a random selection from the group of plausible species. The environmental traits influence the probability of the presence of individual species but do not determine composition of simple microbial assemblies.

<sup>2</sup>Ecology, Pontifical Catholic University, Santiago, Chile

**Background**

Mangrove ecosystems are coastal estuarine systems confined to the tropical and subtropical regions. The Estero Salado mangrove located in Guayaquil, Ecuador, has suffered constant disturbances during the past 20 years, due to industrial wastewater release. Previous work determined that this estuary is one of the most disrupted on earth due to its relationship with anthropogenic disturbance.

**Objectives**

To determine the concentration of heavy metals and nutrients in surface sediments of the Estero Salado in equatorial summer season (February).

To determine the influence of high concentrations of heavy metals in terms of composition of the bacterial microbiome.

**Methods**

A proper understanding of the spatial variations of microbial communities will provide clues about the underline mechanisms that structure microbial groups. In the present study, the analysis of concentration of heavy metals, nutrients and tag sequencing of 16S rRNA V4 was conducted in surface sediments in two mangroves areas in Guayaquil. The first one under the influence of heavy metals and other pollution free

**Conclusions**

Using the high throughput sequencing method, revealed a detailed picture of the spatial variations of the bacterial community structure in the superficial sediment on Estero Salado mangrove.

heavy metals directly influence on bacterial community due to in the contaminated area had a relatively lower alpha-diversity than the area without its presence.

We were able to identify bacterial groups significantly enriched in specific locations. This is the first approach in a mangrove area using tag sequencing and correlating with heavy metals levels.

**Background**

The cape Bon area (Tunisia) is the world leading producer and exporter of Maltese half blood oranges. However the sour orange (*Citrus aurantium*) rootstock is naturally infested by a phytopathogen nematode, *Tylenchulus semipenetrans*, a major nematode pest. Some bacteria and nematophagous fungi demonstrated a nematicidal effect.

**Objectives**

Only few studies have been conducted on the interaction between bacteria and nematodes in the rhizosphere of citrus trees. The aim of this study is to better understand the role of some bacteria in the complex microbial ecosystem of the Tunisian Citrus rhizosphere.

**Methods**

Sixty bacterial strains were isolated from Citrus root trees and egg masses of nematodes. The isolates were screened for i) their nematicidal activity on eggs and on second stage juvenile of *Tylenchulus semipenetrans*, ii) their antifungal activity and iii) their effect on the growth of sour orange roots. To identify the isolates rDNA and/or rpoB gene sequencing was carried out.

**Conclusions**

Among the 60 bacterial isolates, the majority belonged to either *Bacillus subtilis* or *Bacillus cereus*. However, the strains showed a great diversity in their effects i) on the plant host Citrus, ii) on the nematode *Tylenchulus semipenetrans*, iii) on the rhizosphere-associated fungi (i.e. the phytopathogen *Fusarium solani* and predatory nematodes *Monacrosporium cianopagum* and *Arthrobotrys conoides*). Almost 30%

showed antifungal activities against *F. solani*.

These bacterial strains could be used to improve the quality of soil when used in the field by mixing various bacteria, thereby combining antifungal activity and plant growth-promoting bacteria. Large-scale trials should be performed to confirm these promising results.

## **ICE NUCLEATION ACTIVITY IN THE WIDESPREAD SOIL FUNGUS**

### **MORTIERELLA ALPINA**

J. Froehlich-Nowoisky<sup>1</sup>, T.C.J. Hil<sup>2</sup>, B.G. Pummer<sup>1</sup>, P. Yordanova<sup>1</sup>, G.D. Franc<sup>3</sup>,  
U. Pöschl<sup>1</sup>

<sup>1</sup>Multiphase Chemistry, Max Planck Institute for Chemistry, Mainz, Germany

<sup>2</sup>Department of Atmospheric Science, Colorado State University, Ft. Collins, USA

<sup>3</sup>Plant Sciences Department, University of Wyoming, Laramie, USA

### **Background**

Biological residues in soil dust are a potentially strong source of atmospheric ice nucleators (IN). So far, however, the sources and characteristics of biological - in particular, fungal - IN in soil dust have not been characterized.

### **Objectives**

Thus, the objective of this study is a regional investigation of the identity and relative abundances of culturable INA fungi in topsoils, an essential base for improving our understanding of the effects of microorganisms on climate and the hydrological cycle.

### **Methods**

Soil fungi, from a range of different land use and ecosystem types in south-east Wyoming, were analyzed for ice nucleation activity. Ice nucleation active (INA, i.e., inducing ice formation in the probed range of temperature and concentration) fungi were found to be both widespread and abundant, particularly in soils with recent inputs of decomposable organic matter. Across all investigated soils, 8% of fungal isolates were INA. All INA isolates initiated freezing at -5°C to -6°C, and belonged to a single zygomycotic species, *Mortierella alpina* (*Mortierellales*, *Mortierellomycotina*). The IN produced by *M. alpina* seem to be proteinaceous, <300 kDa in size, and can be easily washed off the mycelium.

### **Conclusions**

Ice nucleating fungal mycelium will ramify topsoils and probably also release cell-free IN into it. If these IN survive decomposition or are adsorbed onto mineral surfaces, these small cell-free IN might contribute to the as yet uncharacterized pool of atmospheric IN released by soils as dusts.

### **Background**

Microbial Influenced Corrosion (MIC) is a very aggressive form of corrosion with many proposed mechanisms for its prevention, but existing antifouling solutions include not environmentally friendly biocides. This fact has caused an urgent demand for greener, non-toxic or low-toxicity and longer lasting antifouling compounds and technologies.

### **Objectives**

BIOCORIN project, within FP7-ENVIRONMENT program, aims to develop a green alternative to the coatings and solutions used up to date for MIC corrosion protection and prevention in infrastructures.

### **Methods**

The project is based on a biological phenomenon commonly occurring in nature for microbial population regulation. Microorganisms secrete compounds that inhibit the growth of other microorganisms due to existing antagonism between microbial populations. First step was the isolation and identification of those microorganisms that play a major role in fouling and MIC for different environmental conditions. Several samples were collected from different climate locations for the isolation and identification of microbial populations from metal surfaces. As a result, several microorganisms belonging to bacteria, fungi and yeasts were isolated from the four

different samples and were identified by means of 16S and 18S rRNA gene sequencing.

#### Conclusions

The search of microorganisms with anti-MIC properties resulted in the identification of two candidates with the ability to synthesize compounds with antifouling properties. These candidates were integrated in a coating based on sol–gel technology to prevent the MIC corrosion phenomena in a green way. Currently, this technology is under evaluation by means of three case studies with different environmental conditions.

*<sup>3</sup>Centro de Desarrollo de la Biotecnología CSIC, Francisco Vallés 8. 47151. Boecillo, Valladolid, Spain*

**Background**

Corrosion is a worldwide problem and the direct economic loss due to metal corrosion of infrastructures and equipments is estimated to exceed €1.32 trillion per year, which accounts for 3 to 4% of the Gross Domestic Product of industrialized countries.

Among corrosion types, Microbial Induced Corrosion (MIC) is involved in at least 10% of the corrosion of structures, and up to 50% in the case of subterranean pipes.

**Objectives**

BIOCORIN (New Biocoating for Corrosion Inhibition in Metal Surfaces) is a project funded by the European Union under the activities of the Seventh Framework Programme (FP 7-ENVIRONMENT) that aims to develop a green alternative to the coatings and solutions used up to date for MIC corrosion control. Some of the results of this project are presented here, with the identification of several relevant antifouling compounds secreted by environmentally isolated anti-MIC strains via a metabolomic approach.

**Methods**

Metabolites were extracted from three anti-MIC strains. 100 ml cultures incubated in Terrific Broth (TB) at 30°C for 24 h in the presence and absence of a pool of MIC extracts (inducers) originated from several climatic locations around Europe. Each culture broth was recovered and analyzed by means of LC-MS and GC-MS (Acquity UPLC - SYNAPT G2 HDMS system QToF with ESI injection and a Thermo Scientific Focus GC - DSQ II respectively).

**Conclusions**

The metabolomics analysis pointed out the differential expression of 2 compounds by GC-MS and more than 10 compounds for LC-MS (positive mode) between the analyzed anti-MIC strains.

**FEMS-2199**

**DETERMINATION OF FUNGUS PRESENT IN THE AIR TAKEN IN PM10 FILTERS  
TWO NETWORK STATIONS MONITORING AIR QUALITY IN THE VALLE DE  
ABURRÁ (MEDELLÍN – COLOMBIA)**

L. Gaviria<sup>1</sup>, C. Zapata<sup>1</sup>, O. Campuzano<sup>2</sup>, D. Nanclares<sup>1</sup>, D. Grajales<sup>2</sup>

<sup>1</sup>Facultad de Minas, Universidad Nacional de Colombia, Medellín, Colombia

<sup>2</sup>Facultad de Ciencias, Universidad Nacional de Colombia, Medellín, Colombia

**Background**

Air quality is an issue that has come to be of great concern in recent years due to increased production of particulate material. The presence of fungi in the air is partly responsible for some allergies, infections and diseases. Because of this there is a need to study fungal species associated with inhalable particulate matter and its effects on health.

**Objectives**

The aim of the research is to isolate the fungi present in PM10 filters in sampling two Network Monitoring Air Quality in Aburrá Valley, which presented the highest levels of pollution in the city. After isolation fungi are identified and characterized by the types of pathogens.

**Methods**

The microorganisms are absorbed into quartz filters that capture particles diameters smaller than 10 microns (PM10). The filters are exposed to atmospheric air for 24 hours in the HI-VOL PM10 equipment. Subsequently, the filter was incubated in enrichment medium, serial dilutions were made and plated on selective media for fungi (PDA and Sabouraud in this case). After growth, morphological identification is performed.

**Conclusions**

The results of the tests reveal the presence of *Cladosporium* sp., *Fusarium* sp., *Alternaria* sp. y *Rhodotorula* sp. These microorganisms are considered allergens and are associated with the generation of respiratory diseases like asthma, rhinitis, tracheitis, bronchitis, pneumonia, bronchopulmonary mycosis, among others. These findings demonstrate the importance of knowing the microorganisms associated with particulate material breathe as increased air pollutants in the atmosphere increases morbidity and mortality.

## **FEMS-1063**

### **Environmental microbiology - 2**

#### **DIFFUSION SANDWICH SYSTEM, A TOOL TO ACCESS THE MICROBIAL DARK MATTER**

*J. Pascual<sup>1</sup>, M. García-López<sup>1</sup>, O. Genilloud<sup>1</sup>*

*<sup>1</sup>Microbiology, Fundacion MEDINA, Granada, Spain*

#### **Background**

Prokaryotes are the most abundant and diverse life form on Earth. However, to date, we know that only between 0.001% and 1% of total environmental bacteria have been cultivated through standard culture techniques and media, remaining then a rich diversity of bacterial taxa to be isolated and cultured, the so-called microbial dark matter.

#### **Objectives**

The aim of this study was to carry out a proof of concept of a system of miniature diffusion chambers which we have named Diffusion Sandwich System (DSS), as a cheap and user-friendly tool to gain access to previously uncultured bacterial taxa.

#### **Methods**

We did a comparative study of the cultivability and bacterial diversity which could be isolated by using the DSS and with the classical approach based on picking up bacterial colonies from Petri dishes. Further both culture-dependent approaches were compared with the bacterial diversity present in the same ecological niche but analyzed in-depth by pyrosequencing the metagenomic 16S rRNA gene.

#### **Conclusions**

The culturability obtained by using the miniaturized chambers was 2-log<sub>10</sub> units higher than with the classical approach. Unlike the classical approach, the relative abundances of taxa isolated with the DSS was in line with those actually present in the ecological niche, allowing in fact to isolate representatives of several underrepresented phyla such as *Acidobacteria*, *Verrucomicrobia* and *Gemmatimonadetes*, which constitute new taxa into these phyla.

**Environmental microbiology - 2**

## **MARINE PHAGES AS MARKERS OF REACTIVE TRANSPORT OF THE COLLOIDAL PARTICLES IN THE CRITICAL ZONE**

N. Ghanem<sup>1</sup>, A. Chatzinotas<sup>1</sup>, H. Harms<sup>1</sup>, L.Y. Wick<sup>1</sup>

<sup>1</sup>*Department of Environmental Microbiology,  
Helmholtz Centre for Environmental Research, Leipzig, Germany*

### **Background**

Little is known about the factors determining the eligibility of marine phages as specific markers of hydrological flow and reactive transport of colloidal particles in the Earth's Critical Zone (CZ). Marine phages and their bacterial hosts are naturally absent in soil, can be applied as tracers at high concentration and be detected as little as one phage/mL in water.

### **Objectives**

Within the DFG Collaborative Research Center – AquaDiva we evaluated the effects of phage characteristics (morphology, surface property), water flow regimes as well as the role of mycelial networks on transport of marine phages in laboratory experiments.

### **Methods**

Phages were characterized by electron microscopy, dynamic light scattering and water contact angle analysis (CA) for their size/morphology, surface charge ( $\zeta$ ) and hydrophobicity. Sand-filled percolation columns and a modified high-throughput plaque assay combined with fluorescence microscopy counting were used to quantify phage deposition during percolation.

### **Conclusions**

Our data show that marine phages exhibit differences in their deposition efficiency depending on their size, surface charge and hydrophobicity. For instance, the bigger (60 nm), more hydrophobic (CA = 78°) and poorly charged ( $\zeta_{\text{TM, pH=7-8}} = -13 \text{ mV}$ ) PSA-HM1 phage exhibited a higher deposition efficiency than smaller (30 nm) and less hydrophobic (CA = 52°) H6/1 phages. Interestingly however, both marine phages showed lower retention than terrestrial T4 phages exhibiting similar characteristics than HM1. We conclude that marine phages have a high potential for the use as sensitive tracers in terrestrial habitats with their surface properties playing a crucial role for their transport.

## BIOSORPTION OF CARCINOGENIC PENTACHLOROPHENOL FROM AQUEOUS SOLUTIONS BY FUNGUS *ASPERGILLUS NIGER* BIOMASS

R. Shokoohi<sup>1</sup>, S. Azizi<sup>1</sup>, S.A. Ghiasian<sup>2</sup>, J. Fredma<sup>3</sup>

<sup>1</sup>Department of Environmental Health Engineering,  
Faculty of Health Hamadan University of Medical Sciences, Hamadan, Iran

Hamadan University of Medical Sciences Psoriasis Research Center, Hamadan, Iran

<sup>3</sup>Department of Epidemiology and Biostatistics,  
Faculty of Health Hamadan University of Medical Sciences, Hamadan, Iran

### Background

Pentachlorophenol (PCP) is a hazardous agent in water and soil that poses a significant risk to human health. The toxicity associated with PCP occurs in low doses and mainly affect liver, kidney and central nervous system.

### Objectives

The purpose of this study was to investigate the biosorption of PCP on *Aspergillus niger* biomass as a method for removal of PCP from aqueous solutions.

### Methods

The modified *A. niger* biomass with NaOH was used to adsorb the PCP. The impacts of various experimental parameters such as initial PCP concentration, pH of solution, contact time, and biomass dosage were investigated and optimal conditions were identified. The experimental data were evaluated by various isotherm and kinetic models.

### Conclusions

The correlation of contact time, pH and initial concentration with the biosorption of PCP by *A. niger* biomass was statistically significant ( $P < 0.001$ ). The PCP removal increased with decreasing of solution pH and maximum adsorption was obtained at the pH 3. The equilibrium sorption capacity was increased by increasing initial PCP concentration from 10 to 40 mg/l of 4.23 to 11.65 mg/g, while the PCP removal efficiency decreased from 87 to 55%. Both Langmuir and Freundlich isotherms well described adsorption equilibrium of PCP on *A. niger* biomass. For all cases, the correlation coefficients for the second order kinetic model were close to one.

*A. niger* biomass can be used to reduce the toxicity of aqueous solutions containing PCP in acidic pH conditions. PCP concentration in water and soil poses a great hazard to human health, so its removal by fungi is applicable and commercial.

**FEMS-2716**

**Environmental microbiology - 2**

## **CULTURE-INDEPENDENT APPROACH FOR THE CHARACTERIZATION OF THE BACTERIAL COMMUNITY IN HAEMODIALYSIS WATER**

M. Gomila<sup>1</sup>, C. Prince<sup>1</sup>, A. Busquets<sup>1</sup>, J. Gascó<sup>2</sup>, E. García-Valdés<sup>1</sup>, J. Lluçat<sup>1</sup>

<sup>1</sup>Biology, University of the Balearic Islands, Palma de Mallorca, Spain

<sup>2</sup>Nephrology, Hospital Universitario Son Espases, Palma de Mallorca, Spain

### **Background**

The microbiological purity of haemodialysis water and dialysis fluid is crucial in the treatment of patients with chronic renal insufficiency. The presence of bacteria and bacterial-derived products (*i.e.*, endotoxins, sphingolipids, oligonucleotides) can contribute to silent chronic inflammation, secondary amyloidosis, pyrogenic reactions and anemia.

### **Objectives**

The main objective was to characterize the microbial community present in the haemodialysis water used to reconstitute the dialysis fluid at the Hospital Universitario Son Espases (Majorca, Spain). Bacterial community was assessed in samples obtained in November 2012 and 2013 to evaluate the evolution of the species colonizing these pure waters.

### **Methods**

Dialysis water was filtered through 0.22 µm pore size filters. DNA was extracted from the filters, purified and was amplified with two different set of primers: i) 16S rDNA universal primers and ii) selective *Pseudomonas* primers designed for the  $\sigma$ -subunit of the RNA polymerase sequence (*rpoD* gene). Amplicons were pyrosequenced with a 454 System+ GS FLX platform from Roche. Reads obtained were analyzed in order to assess the phylogenetic identification of bacteria present in the community.

### **Conclusions**

The bacterial community present in the dialysis water is very complex, with microorganisms highly diverse and adapted to the oligotrophic habitats, not usually detected routinely in clinical microbiology laboratories. This community is maintained in the two years period of this study. Based on the 16S rRNA gene pyrosequencing analysis the  $\alpha$ -*Proteobacteria* class is the most abundant. The pyrosequencing of the *rpoD* amplicon showed a high number of putative novel species of *Pseudomonas* showing a high diversity still not described.

**FEMS-2515**

**Environmental microbiology - 2**

## **ISOLATION, PCR IDENTIFICATION OF DIFFERENT BACTERIAL GROUPS AND PHYLOGENETIC CLASSIFICATION**

A. Guermouche<sup>1</sup>, F. Bensalah<sup>1</sup>, J. Gury<sup>2</sup>, R. Durand<sup>2</sup>

<sup>1</sup>Biology, Laboratory of Microbiology Genetics /Es-Senia university Oran Algeria, Oran, Algeria

<sup>2</sup>Equipe Environnement et Microbiologie, UMR IPREM5254 IBEAS – Université de Pau et des Pays de l'Adour Pau France, Pau, France

### **Background**

Because of their massive utilization, hydrocarbons are major pollutants of soils and aquifers. Biodegradation is a key aspect of the fate of pollutants in the environment.

### **Objectives**

It is based on the Gas Chromatographic and Thin Layer Chromatography (TLC) coupled with a Flame Ionization Detector (FID) analysis of hydrocarbons, after incubation in optimal conditions of major compounds in crude oil (saturates and aromatics fractions).

### **Methods**

Using a method of gene sequencing 16S rDNA, the identification of bacteria adapted to soil was determined. Based on nearly full length 16S rRNA gene sequencing analysis, a phylogenetic trees was constructed. Capacity of degradation of selected bacteria and the presence or absence of functional genes coding for the initial oxidation of hydrocarbons (*alkB*, *nahAc*, *nidA*) were studied.

### **Conclusions**

The results indicate that the *Gamma-Proteobacteria* group was the main actor of this degradation. *Pseudomonas* sp, specific bacterial group suitable for petroleum hydrocarbon pollution has the ability to metabolize (single culture) a high mass residues, Pristane (*n*-C19) at 35.11% and Benzo[a]Pyrene (*n*-C20) at 33.93% and co-metabolize (in consortium) fractions in petroleum-hydrocarbon, 50.44% of saturates and 30.42% of aromatics compounds. Biodegradation efficiency of soil microflorae depended on the specific metabolic pathways of some microorganisms and on the cooperation within microbial population. This study provides a better understanding of the adaptation of bacteria inhabiting polluted environments and for developing and implanting adequate bio-strategies in the future to enhance oil in contaminated soil and the biotreatment of oily waste water in refineries.

**Environmental microbiology - 2**

**EXTRACTIVE MEMBRANE BIOFILM REACTORS (EMBFR) FOR BIOREMEDIATION OF METHYL TERT-BUTYL ETHER CONTAMINATED GROUNDWATER: A LAB-SCALE STUDY.**

I.M. Guisado<sup>1</sup>, J. Purswani<sup>1</sup>, R.M. Wittich<sup>2</sup>, J. González-López<sup>1</sup>, C. Pozo<sup>1</sup>

<sup>1</sup>Department of Microbiology, Universidad de Granada, Granada, Spain

<sup>2</sup>Department of Environmental Protection,  
Experimental Station of the Zaidín Spanish High Council for Scientific Research,  
Granada, Spain

**Background**

Among the strategies developed for contaminated groundwater bioremediation, those based on the use of bacteria adhering to inert supports and established as biofilms, have gained great importance in this field. The EMBFR technology offers productive solutions for the removal of volatile compounds like methyl *tert*-butyl ether (MTBE) and other contaminants from water bodies. The EMBFR is based on extractive semipermeable (silicon) membranes through which the contaminants migrate to the biological compartment in which microorganisms with MTBE biotransformation and/or mineralization capacities grow in mineral salts medium, forming a catalytic biofilm on the membrane surface.

**Objectives**

The objective of this study was to assess the use of three bacterial strains (*Paenibacillus* sp. SH7 CECT 8558, *Agrobacterium* sp. MS2 CECT 8557, and *Rhodococcus ruber* EE6 CECT 8612) previously isolated from gasoline contaminated environments, and used as inoculum in a lab-scale EMBFR running for 28 days under aerobic conditions.

**Methods**

Three different retention times (1h, 6 h, and 12 h) were employed. Degradation rates were determined daily by gas chromatography - mass spectrometry, and the biofilm established by the bacterial strains on the semipermeable membrane was observed by FESEM at the end of each experiment. Acute toxicity of the effluents was determinate by Microtox<sup>®</sup> assay (EC<sub>50</sub>).

**Conclusions**

The results achieved from MTBE degradation, biofilm formation and toxicity analysis showed that these bacterial strains could be excellent candidates for use as selective inocula in EMBFR technology for MTBE bioremediation.

**DIARRHEAL BACTERIAL PATHOGENS ARE FREQUENT IN THE CHOQUEYAPU RIVER IN BOLIVIA, AND POSE A RISK OF TRANSMISSION TO FRESH PRODUCE BY CONTAMINATED IRRIGATION WATER**

C. Guzman Otazo<sup>1</sup>, L. Gonzales<sup>2</sup>, V. Poma<sup>3</sup>, V. Iñiguez<sup>3</sup>, A. Sjöling<sup>1</sup>

<sup>1</sup>*Department of Microbiology Tumor and Cell Biology, Karolinska Institutet, Stockholm, Sweden*

<sup>2</sup>*Department of Microbiology and Immunology, Institute of Biomedicine Sahlgrenska Academy, Gothenburg, Sweden*

<sup>3</sup>*Department of Enteropathogens, Institute of Molecular Biology and Biotechnology, La Paz, Bolivia*

**Background**

Water borne diarrheal pathogens might accumulate in river water and present a potential contamination risk of drinking and irrigation water.

**Objectives**

In this study, we show how pathogens can accumulate and be transported in the river Choqueyapu in La Paz and contaminate fresh produce irrigated by river water.

**Methods**

Using qPCR absolute quantification methods, we found a seasonal and spatial variation in the number of pathogen gene copies per ml of river water with a high peak of *Campylobacter* *ssp.* that contaminated otherwise clean water in a watershed at the Altiplano plateau, after the peak of the rainy season in February 2014. High levels of *Campylobacter*, *Salmonella* and enterotoxigenic *E. coli* (ETEC) were subsequently isolated in sampling points downstream along the river and finally identified in vegetables rinse water.

**Conclusions**

These results indicate that distant water contaminations may be transported all the way to the agricultural area. In addition, we found that ETEC carrying the heat labile toxin (LT) alone was much more prevalent in water than other ETEC carrying the heat stable toxin (ST). Hence ETEC with different toxin profiles might have different reproduction and survival ability in water. The results show that the absolute levels of several diarrheal pathogens are high in contaminated river water in the central part of La Paz and although this water is not accessible by humans at this spot several of the pathogens end up in the downstream river water used for irrigation of crops where they might contaminate vegetables.

## **STUDY ON O, M, P-XYLENE DEGRADATION AND ITS RELATED GENES IN RHODOCOCCLUS SPP. J7**

J. Her<sup>1</sup>, S. Lee<sup>1</sup>

<sup>1</sup>*Life science, Kyonggi University, Suwon, Korea*

### **Background**

Xylene, an aromatic hydrocarbon, can be easily found in gasoline contaminated soil and composed of three isomers [ortho (o-), meta (m-) and para (p-) xylene]. Many bacterial strains have been reported to grow on omp-xylene isomers, but few studies have been performed to degrade them simultaneously. Xylene is known for its wide usage in tissue processing, staining and cover slipping and can find easily in ground water. Due to volatile property of xylene isomers, they can spread easily from groundwater to the air.

### **Objectives**

Once human is exposures to xylene, central nervous system could be damaged. So we tried to decrease amount of xylene emitted from factory using soil bacteria.

### **Methods**

Strain J7, belong to the genus *Rhodococcus* was isolated from total petroleum hydrocarbon contaminated site in Korea. Xylene degradation ability was evaluated using 90ppm of xylene mixture (30 mg/L individually) and analyzed by Agilent GC 6890N with Flame ionization detector (FID). The metabolites are analyzed using GC-MS and the pathway of degradation was construed. Target was amplified by PCR using genomic DNA and PCR products were sequenced at Marcrogen (Korea) and compared with other reference genes.

### **Conclusions**

From this study, we confirmed that strain J7 can degrade o, m, and p-xylene at the same time and based on the data, we have constructed that it follows TOL pathway with high efficiency. The catechol-1,2-dioxygenase gene was amplified and conforming that it followed ortho-cleavage pathway.

Chaubepur, Kanpur 209 203 India

\*\*Shri Shakti College, Ghatampur, Kanpur 209 206 India  
itisha.micro@gmail.com, kushwaharks@gmail.com

**Abstract**

The large amount of keratinous waste produced and their localized accumulation create a serious disposal problem leading to environmental pollution. Keratin in forms of animal waste such as hairs, nails, horns, hooves and feathers ultimately comes to soil and if it remains there make pathogenic reservoirs because it is degraded by fungi which have pathogenic potential. On the other hand keratin when degraded by fungi nitrogen is slowly released in the soil and may be utilized by plants as manure. Keratinophilic fungi frequently occurring in soil were selected for hen feather and keratin azure degradation individually and in combination in different sets in soil. Five selected fungi *Acremonium implicatum*, *Chrysosporium queenslandicum*, *Chrysosporium pannicola*, *Malbranchea pulchella* and *Verticillium lecanii*, when used in combination with *Chrysosporium keratinophilum* showed feather and keratin azure degradation. Further feather and keratin azure degradation was monitored in soil when these were used individually and in combination with *C. keratinophilum* and almost above 90% degradation was recorded. The determination of amount of keratin degradation in soil by using individual fungus and fungi in combination is of immense importance in order to find out how much keratin is degraded in soil. The measurement of feather and keratin azure degradation in soil by using five fungi singly and in combination with *C. keratinophilum* presented here for the first time.

**LOW BIOMASS DNA AND RNA EXTRACTION IMPROVES BY USING G2 BLOCKINGREAGENT WITHOUT ANY BIAS IN METAGENOMC ANALYSIS**

C. Jacobsen<sup>1</sup>, T.K. Nielsen<sup>2</sup>, J. Bælum<sup>3</sup>

<sup>1</sup>*CENPERM Geochemistry, Geological Survey of Denmark and Greenland, Copenhagen, Denmark*

<sup>2</sup>*Environmental Sciences, University of Aarhus, Roskilde, Denmark*

<sup>3</sup>-, *Chr Hansen, Hørsholm, Denmark*

**Background**

Low biomass samples can be extremely challenging when extracting DNA and RNA. Many scientists have been adding various sources of RNA or DNA to the samples to aid a high recovery, however this makes the samples only useable for specifically directed analysis, while metagenomic analysis is hampered.

**Objectives**

A new product G2 that are shown to improve DNA and RNA yield from low biomass samples are tested for use in metagenomic analysis as well as if several labs can repeat the results in a ring test.

**Methods**

We have included analysis of influence of G2 on both full genome sequencing and various amplicon sequencing techniques. Further a Q-PCR analysis was performed after 12 laboratories in a ring test were applying G2 to one sampletype.

**Conclusions**

G2 was shown to be free of contaminating DNA both using 16SrDNA based Q-PCR and amplicon sequencing, further a metagenomic analysis clearly indicated that no traces of the original DNA could be found in a metagenome analysis. The ringtest showed that the participating laboratories all had a higher yield using G2 but also that the participating laboratories did perform very different.

Department of Food Science and Technology, Vienna, Austria

<sup>2</sup>University of Natural Resources and Life Sciences,  
Department of Food Science and Technology, Vienna, Austria

<sup>3</sup>University of Natural Resources and Life Sciences,  
Department of Food Science and Technology, Vienna, Austria

**Background**

Terrestrial microorganisms, especially those from the order Actinomycetales, formed the backbone for the golden age of antibiotic discovery, and are the source of the vast majority of FDA-approved antimicrobial agents.

**Objectives**

In this study, the antimicrobial activity and diversity of genes associated with secondary-metabolite biosynthesis of Actinobacteria isolated from fresh fish gut microbiota namely *Schizothorax zarudnyi* and *Schizocypris altidorsalis* were investigated.

**Methods**

Strains of six groups of fish and human pathogenic bacteria were selected and all the isolated actinomycetes were tested for their antibacterial activity against the pathogenic bacteria. The antagonistic activity of actinomycetes was tested by the perpendicular cross streak method.

The PCR-based approach was applied to detect the presence of three important biosynthetic genes including polyketide synthases (PKS-I and PKS-II), non-ribosomal peptide synthetase (NRPS). The PCR amplicons and their origins were further confirmed by sequencing.

**Conclusions**

According to results all isolates possess at least two types of the investigated biosynthetic genes. This study demonstrates the significant diversity of genes associated with secondary-metabolite biosynthesis of Actinobacteria in the fish gut microbiota and its potential to produce biologically active compounds.

**EFFECTS OF NITROGEN FERTILIZER ON NITRITE-DEPENDENT ANAEROBIC METHANE OXIDATION BACTERIA IN A FLOODED RICE PADDY**

S.E. Jeong<sup>1</sup>, H.J. Lee<sup>1</sup>, C.O. Jeon<sup>1</sup>

<sup>1</sup>Life Science, Chung-Ang University, Seoul, Korea

**Background**

Nitrite-dependent anaerobic methane oxidation (n-damo) may be an important process in the biogeochemical cycles of carbon and nitrogen. However, the inquiry of n-damo bacteria in rice paddy is rarely explored.

**Objectives**

The aim of this work was to investigate the effects of nitrogen fertilizer on the communities of n-damo bacteria in a flooded rice paddy.

**Methods**

Different amounts of urea (0, 45, 90, and 180 kg ha<sup>-1</sup>) were applied to a flooded rice paddy transplanted with a rice cultivar (*Oryza sativa*) and soil cores were sampled after 15 days of third urea application. The soil cores were divided into top (0–5 cm), middle (10–15 cm), and bottom (20–25 cm) layers and the diversity and abundance of n-damo were investigated using T-RFLP (Terminal-Restriction Fragment Length Polymorphism) and quantitative PCR approaches, respectively. A clone library was constructed for the T-RFLP analyses of 16S rRNA gene fragments of n-damo. DNA samples were retrieved from the soil core samples and the abundances and diversities of n-damo were investigated using T-RFLP.

**Conclusions**

Abundance of n-damo in a flooded rice paddy was not significantly different although different amounts of urea were applied. However, the phylogenetic analysis of *Methylobacterium oxyfera*-like 16S rRNA gene sequences revealed that n-damo was a little diverse depending on urea application and soil depths. Sequences of Top 90 soil sample fell into just one group, while sequences of Bottom 180 were classified into three groups. In addition, the diversity analysis of n-damo in response to different amounts of urea will be performed and discussed.

**MICROFLUIDIC CHIP-ASSISTED DNA PREPARATION FROM ENVIRONMENTAL SAMPLES SPIKED WITH FRANCISELLA TULARENSIS AND BACILLUS THURINGIENSIS**

S. Julich<sup>1</sup>, C. Gärtner<sup>2</sup>, H. Tomaso<sup>1</sup>

<sup>1</sup>*Institute of Bacterial Infections and Zoonoses, Friedrich-Loeffler-Institut, Jena, Germany*

<sup>2</sup>*microfluidic ChipShop GmbH, Jena, Germany*

**Background**

The detection of bacteria from environmental samples using nucleic acid amplification depends on efficient DNA extraction and purification to remove PCR Inhibitors.

**Objectives**

DNA extraction and purification from spiked air, natural water, swab and soil samples was performed using a microfluidic chip device. A protocol was established that was suitable for the detection of two representative bacteria, *Francisella (F.) tularensis* (Gram-negative) and *Bacillus (B.) thuringiensis* (Gram-positive).

**Methods**

The procedure is composed of thermal, chemical and enzymatic lysis methods combined with on-chip DNA purification using paramagnetic particles for reversible DNA attachment. Polymeric microfluidic chips with rhombic cavities were mounted on a device with a regulated heating unit and a movable magnet that enables particle mixing for careful washing and elution. Serial 10-fold dilutions of the bacteria suspensions were tested. DNA preparations were analysed by real-time PCR assays to determine the detection limits that can be achieved.

**Conclusions**

Detection of both species of bacteria was possible from all tested matrices. The detection limits in air samples corresponded to 7 GE/10 l for *F. tularensis* and 0.7 GE/10 l for *B. thuringiensis*. In river water the limits were 10<sup>2</sup> GE/ml *B. thuringiensis* and 10<sup>3</sup> GE/ml *F. tularensis*. The achieved detection limits for soil samples corresponded to 2.7·10<sup>3</sup> GE/mg *F. tularensis* and 2.7·10<sup>2</sup> GE/mg *B. thuringiensis* and

with swab samples  $4 \cdot 10^3$  GE/cm<sup>2</sup> *F. tularensis* and  $4 \cdot 10^2$  GE/cm<sup>2</sup> *B. thuringiensis* were detected. Future developments will focus on the development of integrated lab-on-a-chip system combining sample preparation with on-chip PCR technologies.

**PLANT GROWTH PROMOTING RHIZOBACTERIAL EFFICACY IN COWPEA  
(VIGNA UNGUICULATA (L.) WALP.)**

K. Kannan<sup>1</sup>, V. Rajesh Kannan<sup>1</sup>

<sup>1</sup>Microbiology, Bharathidasan University, Tiruchirappalli, India

**Background**

Plant growth promoting rhizobacteria (PGPR) are known to influence the growth of the plant by various plant growth promoting activities such as Indole Acetic Acid (IAA) production, Phosphate solubilization activity, Ammonia production (NH<sub>3</sub>), Nitrogen fixation, Siderophore production and Hydrogen cyanide production (HCN). In search for the potential PGPR from the Rhizosphere soil of cowpea, a total of 16 rhizobacteria (B1-B6 & D1-D9) were isolated. By comparing the results two potential rhizobacteria (B6 & D4) have been selected for the further evaluation of Plant Growth Promoting (PGP) activity. These isolates biochemically characterized, B6 and D4 confirmed as *Pseudomonas* and *Bacillus* by 16SrRNA gene sequencing. *Invitro* and *Invivo* Nursery field studies revealed that 100 % seed germination rate using *Bacillus safensis* and 92% for *Pseudomonas aeruginosa* showing promising results. The study showed the characters of benefits to use these organisms as biofertilizers for sustainable agriculture to improve crop yield.

**Objectives**

This study was aimed to focus on the PGP activities of the two potential rhizobacteria and growth promotion

**Methods**

*IAA production (Lwin et al. 2012)*

*Siderophore production (Arnow 1987)*

*Phosphate Solubilization Activity (Qureshi et al. 2012)*

*Hydrogen Cyanide Production (Ahmad et al., 2008)*

*Ammonia Production (Cappucino and Sherman, 1992)*

*Nitrogen fixation activity (Lwin et al. 2012)*

*16S rRNA Sequencing*

*Seed germination rate and seedling vigor index (Ng LC et al. 2012)*

*Nursery pot experiment*

## **Conclusions**

Rhizobacteria isolated from the cowpea rhizosphere *Pseudomonas aeruginosa* VRKK1 and *Bacillus safensis* VRKK2 acts as the potential PGPR. *Pseudomonas aeruginosa* showed 100% germination rate, *Bacillus safensis* showed 92 % germination

**PROTEOMICS REVEALS OSMOTIC STRESS ADAPTATIONS OF SHEWANELLA BALTICA, PARACOCCLUS SP. AND FLAVOBACTERIUM SP. IN A UNIQUE ENVIRONMENT OF THE BALTIC SEA**

J. Karczewska-Golec<sup>1</sup>, P. Golec<sup>2</sup>, S. Markert<sup>3</sup>, M. Kochanowska-Lyzen<sup>1</sup>, T. Schweder<sup>3</sup>, A. Szalewska-Palasz<sup>1</sup>

<sup>1</sup>Department of Molecular Biology, University of Gdansk, Gdansk, Poland

<sup>2</sup>Laboratory of Molecular Biology affiliated with the University of Gdansk, Institute of Biochemistry and Biophysics Polish Academy of Sciences, Gdansk, Poland

<sup>3</sup>Department of Pharmaceutical Biotechnology, Institute of Pharmacy E-M-A University of Greifswald, Greifswald, Germany

**Background**

Baltic Sea constitutes a unique environment of brackish water conditions, with dynamic, regional shifts in salinity, mainly due to varying freshwater inflows.

**Objectives**

The goal of the study was to identify physiological and molecular strategies that allow Baltic Sea bacteria to confront this challenging habitat.

**Methods**

Three bacterial Baltic Sea representatives, identified as *Shewanella baltica*, *Flavobacterium* sp. and *Paracoccus* sp. on the basis of 16S rRNA sequencing and MALDI-TOF analyses, were cultured under controlled growth conditions in a chemostat system and analyzed with a combined approach of 2-DE, multiplex fluorescent staining of proteins in gels and LC-ESI-MS/MS and/or MALDI-TOF/TOF-driven protein identifications.

**Conclusions**

Tracking down of proteome dynamics in *Shewanella baltica*, *Flavobacterium* sp. and *Paracoccus* sp. in response to the salinity shifts characteristic of the Baltic Sea (2, 7 and 20‰) allowed the identification of a subset of proteins, both of the general stress response group and of other functional categories, differentially expressed under osmotic challenges tested. Wide variations in adaptations to osmotic stress were revealed in the three strains studied, with *Paracoccus* sp. requiring a significantly less

number of proteins to survive in the osmotic stress conditions in comparison to *Shewanella baltica* and *Flavobacterium sp.*

Taken together, our study uncovered well-coordinated and highly regulated protein inventories in the marine bacteria studied, with a large number of novel candidates for stress response players, thus laying a ground work for understanding of the complexity of microbial adaptive processes in the intriguing ecosystem of the Baltic Sea.

**BIOSORPTION OF CHROMIUM BY PSEUDOMONAS SP ISOLATED FROM SOIL CONTAMINATED WITH PETROLEUM OF KHOUZESTAN, IRAN**

H. Khorassani<sup>1</sup>, S.M. Meybod<sup>2</sup>

<sup>1</sup>Microbiology, IAU Kerman Branch, Kerman, Iran

<sup>2</sup>Microbiology, IAU Sirjan Branch, Sirjan, Iran

**Background**

In recent decades, the biological methods have been used for remove environmental contaminants such as heavy metals. Resistance to metals is important for this aim.

**Objectives**

The objective of this research is the isolation of chromium resistant strains.

**Methods**

Five samples of soil were collected under sterile conditions and transferred to laboratory immediately. Soil samples were homogenized and diluted up to 10<sup>-10</sup> with sterile normal saline. These samples were cultured in LB agar containing 5ppm of chromium in order to isolation of resistant strains. These strains were isolated and cultured in Macconkey agar for isolation of appropriate strains. Isolated bacteria were identified by biochemical tests. Then, the MIC test was used for screening of resistant strains. The best conditions of bacterial growth were found in the presence of chromium in various temperatures, rate of shaking and values of pH by spectrophotometry at 600nm in the overnight of cultivation. Metal adsorption test measured under optimal conditions by atomic absorption spectroscopy.

**Conclusions:** From total of 24 strains of isolated Pseudomonads, 14 strains were resistant to chromium. The top strain (Mac2) has eliminated 35.60% of chromium from aqueous culture mediums in optimal conditions (pH: 8, Temp: 40°C and Shaking rate: 200rpm). The results were verified using statistical method named the general linear model. The contaminated zones should be clean, because heavy metals in various physicochemical forms have been considered as environmental pollutants. This bacterium can be used for studies of bioremediation of contaminated sites to chromium.

**Environmental microbiology - 2**

## **MICROORGANISMS IN CAVES: IMPORTANCE, DIVERSITY AND CONSERVATION**

I. Kieraite-Aleksandrova<sup>1</sup>, N. Kuisiene<sup>1</sup>

<sup>1</sup>*Department of Microbiology and Biotechnology, Vilnius University, Vilnius, Lithuania*

### **Background**

Harsh conditions and isolation lead to formation of unique microbial communities, making caves a promising yet poorly understood field for study of biodiversity. Studies of microbial communities in caves may provide insights of microbial relationships, biogeochemical processes, evolution and even functioning of extraterrestrial life. Furthermore, they can lead to the discovery of novel bioactive compounds and draw attention to the importance of cave conservation.

### **Objectives**

The goal of the project was to analyze the microbial communities of different caves and evaluate the impact of human activity within pristine and disturbed cave areas.

### **Methods**

Barcode pyrosequencing of 16S rRNA genes was used to investigate the microbial diversity of two oligotrophic Karabi Jaila (Crimea) caves and the world's deepest cave Krubera-Voronja (Caucasus).

### **Conclusions**

It was found that 12 % of 16S rRNA gene sequences from the more frequently visited areas of Crimean caves belonged to previously unclassified bacteria. In the samples of rarely visited branches the sequences belonging to unclassified bacteria comprised 46 %. On the other hand, only 5 % of sequences found in more pristine areas of Krubera-Voronja cave belonged to unclassified bacteria. 6 % of unclassified sequences were found in the main branch of the cave where human activity is particularly intense. Disturbed areas of all caves demonstrated broader diversity of known phyla as well as significantly higher abundance of sequences belonging to *Bacteroidetes*, which are known to be indicators of fecal pollution. The authors are thankful to the Lithuanian Science Council for the financial support (project No. MIP-005/2014).

**FEMS-1237**

## **IDENTIFICATIONS OF PROPER METHODS TO DETERMINE LEGIONELLA PNEUMOPHILA BACTERIA EXPOSED TO DIFFERENT ENVIRONMENTAL CONDITIONS**

*I.P.E.K. Ada<sup>1</sup>, A. Kimiran Erdem<sup>1</sup>*

<sup>1</sup>*Faculty of Science Department of Biology, Istanbul University, Istanbul, Turkey*

### **Background**

*Legionella* which is the agent of Legionnaires' disease in natural and man-made water systems. *Legionella* bacteria pass to the viable but non-culturable (VBNC) phase due to the environmental conditions such as temperature, pH and disinfectants. After examining under laboratory conditions the water samples containing *Legionella* bacteria, have been exposed to environmental factors, it was shown that those bacteria couldn't colony form medium, but this result does not mean that the bacteria are not present in a sample or an environment.

### **Objectives**

The aim of the present study is to detect the most suitable methods for the recovery of *L. pneumophila* bacteria exposed to different environmental conditions.

### **Methods**

In the current study, first of all, the detection limits of culture, fluorescent *in situ* hybridization (FISH) and semi-nested polymerase chain reaction (PCR) methods for different *L. pneumophila* concentrations ( $10^2$ - $10^{10}$  cell/L) was determined. Later, the recovery of *L. pneumophila* bacteria from the water samples including *L. pneumophila* bacteria that expose to different environmental conditions (temperature, pH and biocide) has been assessed by culture, FISH and semi-nested PCR methods.

### **Conclusions**

In the present study, the detection limit of *L. pneumophila* bacteria was determined as  $10^3$  cell /L for the culture method,  $10^5$  cell/L for FISH method and  $10^6$  cell /L for semi-nested PCR method. It was determined that FISH and semi-nested PCR methods are suitable methods for the recovery of *L. pneumophila* bacteria that are subject to different environmental conditions from the water samples.

**ANTIBIOTIC RESISTANCE PATTERN OF PSEUDOMONAS SPP. ISOLATED FROM THE TOTAL COURSE OF THE RIVER DANUBE**

G. Zarfel<sup>1</sup>, A. Kirschner<sup>2</sup>, D. Toplitsch<sup>3</sup>, A. Liebmann<sup>3</sup>, R. Baumert<sup>1</sup>, B. Folli<sup>1</sup>, M. Lipp<sup>1</sup>, A.J. Grisold<sup>1</sup>, A.H. Farnleitner<sup>4</sup>, C. Kittinger<sup>1</sup>

<sup>1</sup>Institute of Hygiene, Medical University of Graz, Graz, Austria

<sup>2</sup>Institut of Hygiene and Applied Immunology, Medical University of Vienna, Vienna, Austria

<sup>3</sup>Institute of Molecular Biosciences, Karl-Franzens University of Graz, Graz, Austria

<sup>4</sup>Institute of Chemical Engineering, Vienna University of Technology, Vienna, Austria

**Background**

This study was part of the Joint Danube Survey 3 (JDS3), the world's biggest river research expedition of its kind.

**Objectives**

The aim of the study was to determine the presence of acquired antibiotic resistance of different bacterial species with clinical impact.

**Methods**

During JDS3 180 water samples were taken over the total course of the river Danube. Samples were mixed with glycerol and stored at -70°C. For isolation five ml of the thawed samples were plated in 0.5 ml portions on *Pseudomonas* selective agar and incubated at 37°. The isolates were tested for species identification with mass spectrometry MALDI-TOF MS (Shimadzu, Japan). Resistance testing was performed as recommended by the European Committee on Antimicrobial Susceptibility Testing (EUCAST). To estimate the presence of carbapenemase modified hodge tests were performed with all isolates resistant to at least one carbapenem.

**Conclusions**

Up to now 496 *Pseudomonas* were isolated, 343 (67%) *Pseudomonas putida*, 120 (25%) *Pseudomonas fluorescens*, all other species were represented by less than 10 isolates but no *Pseudomonas aeruginosa* was observed. Most common resistance was against meropenem (20.4%/ 76 isolates) piperacillin/tazobactam (4.3%/16 isolates) and ciprofloxacin (4.3%/16 isolates). None of the antibiotics were susceptible in all tested strains. Resistances were present all over the tested sampling points with no significant changes downstream. One isolate (*Pseudomonas fluorescens*) was tested positive for the presence of a carbapenemase in modified hodge test. Although the isolated *Pseudomonas* species are clinically less frequent, they are a

possible reservoir for resistance acquisition for other species (especially *Pseudomonas aeruginosa*).

**Environmental microbiology - 2**

**SELECTION OF A SYNTHETIC SOIL MICROBIAL COMMUNITY FOR  
QUANTIFYING EFFECTS OF HYDRATION DYNAMICS ON COMMUNITY  
STRUCTURE AND DIVERSITY**

H. Kleyer<sup>1</sup>, R. Tecon<sup>1</sup>, D. Or<sup>1</sup>

<sup>1</sup>*Soil and Terrestrial Environmental Physics, ETH, Zurich, Switzerland*

**Background**

Soil bacteria play a central role in many ecosystem services such as formation of rhizosphere communities, nutrient transformation and global biogeochemical cycles. Although molecular techniques have uncovered the tremendous bacterial diversity in soil, the mechanisms that control the assembly, functioning and maintenance of complex microbial communities remain largely unknown.

**Objectives**

The study aims at linking dynamics of soil hydration conditions and related biophysical factors with variations in microbial composition and ecological functioning. Understanding factors that shape the dynamics of species abundance is essential to get an insight into the assembly of a microbial community, its functioning and response to induced changes in water availability, a key parameter of soil environments.

**Methods**

To assist with definitive community level observations we designed a synthetic microbial community comprised of 10 well-characterized bacterial species spanning a wide range of soil phyla to be inoculated onto model porous surfaces mimicking soil habitats. The experimental system consists of sand layer placed on porous ceramic surface connected to nutrient reservoir. Fluctuations in hydration conditions are induced by changing the reference nutrient reservoir level to simulate wetting-drying cycles. The activity and composition of the bacterial community is studied using 16S fingerprinting and quantitative PCR.

**Conclusions**

Spatial self-organization of microbial community is highly dependent on the hydration level of their habitat. Subjecting the synthetic community to a range of controlled physico-chemical conditions allows us systematic evaluation of the role of environmental fluctuations on changes in community composition.

**TRANSCRIPTOME ANALYSIS OF THE BALTIC SEA ISOLATES: SHEWANELLA BALTICA, PARACOCCLUS SP. AND FLAVOBACTERIUM SP. SHOWS THEIR SPECIFIC RESPONSE TO OSMOTIC STRESS.**

M. Kochanowska-Lyzen<sup>1</sup>, P. Golec<sup>2</sup>, P. Olszewski<sup>3</sup>, J. Karczewska-Golec<sup>1</sup>, M. Balut<sup>4</sup>, A. Piotrowski<sup>4</sup>, A. Szalewska-Palasz<sup>1</sup>

<sup>1</sup>Department of Molecular Biology, University of Gdansk, Gdansk, Poland

<sup>2</sup>Laboratory of Molecular Biology affiliated with the University of Gdansk, Institute of Biochemistry and Biophysics Polish Academy of Sciences, Gdansk, Poland

<sup>3</sup>Department of Genetics, University of Gdansk, Gdansk, Poland

<sup>4</sup>Department of Biology and Pharmaceutical Botany, Medical University of Gdansk, Gdansk, Poland

**Background**

The Baltic Sea constitutes very specific environment. One of its characteristics are brackish water conditions that are caused by high water input from the surrounding lands and rivers. However, because of its characteristic geographical location, salinity levels change significantly in different parts of the Sea and can extend from 2, through 7 and even up to 20‰.

**Objectives**

The aim of our work is to assess which genes are essential for marine bacteria to adapt to the changes in salinity of their environment.

**Methods**

Three bacteria isolated from Baltic Sea were sequenced using Illumina HiSeq 2,000 platform and characterized as *Shewanella baltica*, *Paracoccus* sp. and *Flavobacterium* sp.. Then, they were cultured in a chemostat system in the minimal marine medium at various salinity conditions. During steady-state growth cells were harvested for RNA extraction and Illumina-based RNA-Seq reads were analyzed with DESeq2 software.

**Conclusions**

The transcriptome analysis of the three strains *Shewanella baltica*, *Paracoccus* sp. and *Flavobacterium* sp. at various salinity levels (bacteria cultured in 2, 7 and 20 ‰) resulted in identification of groups of genes responsible for bacterial survival in the

challenging environment of the Baltic Sea. Each strain is characterized by different response to osmolarity stress, underlying the importance of diverse categories of functional genes in this marine habitat.

## **FUNCTIONAL RESILIENCE OF MICROBIAL ECOSYSTEMS IN SOIL: HOW IMPORTANT IS A SPATIAL ANALYSIS?**

S. König<sup>1</sup>, T. Banitz<sup>2</sup>, F. Centler<sup>1</sup>, K. Frank<sup>2</sup>, M. Thullner<sup>1</sup>

<sup>1</sup>*Environmental Microbiology, Helmholtz Centre for Environmental Research, Leipzig, Germany*

<sup>2</sup>*Ecological Modelling, Helmholtz Centre for Environmental Research, Leipzig, Germany*

### **Background**

Microbial life in soil is exposed to fluctuating environmental conditions influencing the performance of ecosystem services such as biodegradation.

### **Objectives**

However, as this environment is typically very heterogeneous, spatial aspects can be expected to play a major role for the ability to recover from a stress event.

### **Methods**

To determine key processes for functional resilience, scenarios with varying stress intensities were simulated within a microbial simulation model and the biodegradation rate in the recovery phase measured. Besides temporal monitoring, results were analyzed regarding spatial and mechanistic aspects. Parameters including microbial growth and dispersal rates were varied over a typical range to consider microorganisms with varying properties.

### **Conclusions**

Results of the mechanistic and spatial view show that key factors for functional recovery depend on stress intensity and the location of the observed habitats. The limiting factors near unstressed areas are spatial processes (motility and substrate diffusion), with increasing distance microbial growth becomes more important. To confirm this, we repeated the simulations including a dispersal network representing fungi in soil. The system benefits from an increased spatial performance due to higher bacterial mobility.

With these simulations we show the importance of spatial aspects even at the mm-scale for recovering after a severe stress event in a highly heterogeneous environment such as soil. In consequence a spatial-mechanistic view is necessary for examining the functional resilience as the temporal view alone could not have led to these conclusions.

Further research should explore the importance of a spatial view for quantifying functional resilience also after complex stress regimes.

Germany*

<sup>2</sup>*Environmental Microbiology, Helmholtz Centre for Environmental Research, Leipzig,  
Germany*

<sup>3</sup>*Environmental Biotechnology, Helmholtz Centre for Environmental Research,  
Leipzig, Germany*

**Background**

Although bacterial degraders in soil are commonly exposed to fluctuating environmental conditions, the functional performance of the biodegradation processes can often be maintained by resistance and resilience mechanisms.

**Objectives**

However, there is still a gap in the mechanistic understanding of key factors contributing to the stability of such an ecosystem service

**Methods**

Therefore we developed an integrated approach combining microcosm experiments, simulation models and ecological theory to directly make use of the strengths of these disciplines. In a continuous interplay process, data, hypotheses, and central questions are exchanged between disciplines to initiate new experiments and models to ultimately identify buffer mechanisms and factors providing functional stability. We focus on drying and rewetting-cycles in soil ecosystems, which are a major abiotic driver for bacterial activity.

**Conclusions**

Functional recovery of the system was found to depend on different spatial processes in the computational model. In particular, bacterial motility is a prerequisite for biodegradation if either bacteria or substrate are heterogeneously distributed. Hence, laboratory experiments focussing on bacterial dispersal processes were conducted and confirmed this finding also for functional resistance. Obtained results will be incorporated into the model in the next step. Overall, the combination of computational modelling and laboratory experiments identified spatial processes as the main driving force for functional stability in the considered system, and has proved a powerful methodological approach.

**BIOEGO: DEVELOPMENT OF A FUNGAL-BACTERIAL CONSORTIUM-BASED SOIL INOCULANT FOR PLANT GROWTH PROMOTION AND BIOCONTROL**

L. Kredics<sup>1</sup>, P. Körmöczy<sup>1</sup>, B. Bóka<sup>1</sup>, S. Szabó<sup>2</sup>, G. Tarna<sup>2</sup>, M. Chandrasekaran<sup>3</sup>, L. Manczinger<sup>1</sup>, C. Vágvolgyi<sup>1</sup>

<sup>1</sup>Department of Microbiology, University of Szeged, Szeged, Hungary

<sup>2</sup>BioeGO Ltd, Csöndes u. 10/A, Szeged, Hungary

<sup>3</sup>Botany and Microbiology Department, King Saud University, Riyadh, Saudi Arabia

**Background**

There is an emerging need for environment-friendly soil inoculants with favorable effects on crop plants.

**Objectives**

We aimed to develop BioeGO, a fungal-bacterial consortium-based soil inoculant ensuring increased nitrogen fixation, phosphorous mobilization, stem degradation and humus production on the treated fields and providing protective effects against phytopathogenic fungi.

**Methods**

Nitrogen-fixing component was selected from bacteria based on growth capabilities in nitrogen-free medium. Phosphorous-mobilizing and stem-degrading component was selected from *Trichoderma* strains based on cellulase- and phosphatase-producing abilities. Humus-producing component was selected from bacteria based on peroxidase-producing abilities, while biocontrol component was selected from *Trichoderma* strains based on *in vitro* antagonism towards phytopathogenic fungi.

**Conclusions**

An *Azotobacter vinelandii* strain is the nitrogen-fixing component of the soil inoculant with the potential to provide excess nitrogen for crops. Phosphorous mobilization and stem degradation are ensured by a *Trichoderma harzianum* strain producing cellulose-degrading enzymes in the absence of stem residues, while this ability is increased 10-15 fold in the presence of grinded maize stem. It also produces large amounts of enzymes liberating organically bound phosphorous. A *Streptomyces albus* strain with excellent peroxidase-producing abilities was selected as the humus-producing component, while a *Trichoderma asperellum* isolate with outstanding antagonistic abilities towards *Fusarium*, *Phoma*, *Alternaria*, *Botrytis* and *Rhizoctonia*

strains is the biocontrol component of BioeGO. Microbial components of the consortium do not have negative effects on each other, thereby all beneficial effects can occur simultaneously, complementing each other. This research was supported by grant TÁMOP-4.1.1.C-12/1/KONV-2012-0012. Csaba Vágvolgyi thanks the visiting professor program, Deanship of Scientific Research, King Saud University, Riyadh.

## **CHARACTERIZATION OF POTENTIAL AEROSOLIC IN ACTIVITY OF FUNGAL SPECIES**

A. Kunert<sup>1</sup>, J.F. Scheel<sup>1</sup>, M.L. Krüger<sup>1</sup>, U. Pöschl<sup>1</sup>, J. Fröhlich-Nowoisky<sup>1</sup>

<sup>1</sup>Multiphase Chemistry, Max Planck Institute for Chemistry, Mainz, Germany

### **Background**

Biological aerosol particles are ubiquitous in the atmosphere. Recent findings identified a pool of these particles as potential ice nucleators (IN), which are capable of catalyzing ice formation at relatively warm subfreezing temperatures and thus impact cloud formation and precipitation. Some fungal species have been identified as ice nucleation active (INA) e. g., the ice nucleation capacity of *Fusarium acuminatum* was described already some decades ago but recently more species were discovered to possess IN activity (e.g., *Mortierella alpina*). For fungal IN activity, a protein or at least a proteinaceous compound is hypothesized to be responsible.

### **Objectives**

The aim of the study is to analyze the ability to release cell-free IN into the atmosphere. Therefore, the IN machinery of fungal species is characterized by analytical and molecular biological methods as well as chamber experiments with the ultimate goal to clarify their potential impact on atmospheric cloud formation and water precipitation.

### **Methods**

In this study, liquid chromatography and mass spectrometry is performed to identify proteinaceous compounds of fungal IN. A specific IN trap chamber (IN-TC) is designed to analyze the aerosolic transport capacity of fungal IN. For testing functional IN activity a customized droplet freezing assay is used.

### **Conclusions**

Functional IN active fractions of fungal protein surface extractions can be identified by liquid chromatography and SDS-PAGE. Preliminary IN-TC results show a successful proof of principle suggesting the chamber is capable of collecting aerosolic IN generated of fungal washing water.

## **DEVELOPMENT OF HEAVY METAL ION BIOSENSORS USING SYNTHETIC GENETIC CIRCUITS**

H.J. Kim<sup>1</sup>, J. Haeyoung<sup>2</sup>, S.J. Lee<sup>1</sup>

<sup>1</sup>Infection and Immunity Research Center,

Korea Research Institute of Bioscience and Biotechnology, Daejeon, Korea

<sup>2</sup>Superbacteria Research Center,

Korea Research Institute of Bioscience and Biotechnology, Daejeon, Korea

### **Background**

We previously determined the genome of *Bacillus oceanisediminis* 2691 that was isolated from marine sediment of the South Korean coast and found that many genes encoded heavy metal resistance and efflux systems in the genome. Genes encoding putative cadmium efflux pumps, arsenic efflux pumps, a chromate transporter, and lead-, cadmium-, zinc-, and mercury-transporting ATPases were found in the genome, which are apparently regulated by CadC homologous repressor-type transcription factors.

### **Objectives**

We attempted to develop heavy metal ion biosensors using synthetic genetic circuits with *cadC* genes.

### **Methods**

It was confirmed the transcriptional modulations of CadC-controlled genes in response to various heavy metals in *B. oceanisediminis* 2691 using real-time PCR. Six *cadC* promoter-operator-structural genes were transcriptionally fused with *egfp* gene to make recombinant *E. coli* cells. A variety of heavy metals were treated and specific fluorescence intensities were measured.

### **Conclusions**

Taken together, the results showed that CadC proteins specifically respond to heavy metals and may play separate roles in heavy metal resistances, which have been evolved in the heavy metal abundant marine sediment milieu. In biotechnological aspects, CadC-controlled transcriptional modules could be used in the development of harmful heavy metal bio-sensor.

## CHARACTERIZATION OF COD REMOVAL, ELECTRICITY GENERATION AND MICROBIAL COMMUNITY IN MICROBIAL FUEL CELLS TREATING MOLASSES WASTEWATER

Y. Lee<sup>1</sup>, T. Kim<sup>2</sup>, K. Cho<sup>1</sup>

<sup>1</sup>Department of Environmental Science and Engineering, Ewha Womans University, Seoul, Korea

<sup>2</sup>Ecological Information Management Team, National Institute of Ecology, Choongnam, Korea

### Background

Wastewater microbial fuel cells (MFCs) have advantages in treatment wastewater and electricity production simultaneously. Molasses wastewater (MW) is one of suitable feedstock for wastewater MFCs.

### Objectives

In this study, electricity generation, COD removal, and microbial communities were investigated using 3-types of MFCs which were single-chamber MFCs without proton exchange membrane (PEM) and with PEM (AC-MFCs and ACM-MFCs, respectively) and two-chamber MFCs (H-MFCs).

### Methods

Diluted MW (10,000 mg·L<sup>-1</sup> COD) was continuously fed into the MFCs. Reactor performances in the single-chamber MFCs were similar, indicating that PEM couldn't enhance the reactor performances. COD removal in the single-chamber MFCs (90%) was higher than in the H-MFCs (50%). However, current density in the H-MFCs (80 mA·m<sup>-2</sup>) was 1.4 times of that in the single-chamber MFCs (57 mA·m<sup>-2</sup>). Power density in the H-MFCs (17 mW·m<sup>-2</sup>) was 2.2 times that in the single-chamber MFCs (7.7 mW·m<sup>-2</sup>). Microbial communities of the MFCs were examined using 16S rRNA-iron torrent sequencing. For bacterial community, *Clostridium* (7.6%) and *Geobacter* (4.2) were abundant in the AC-MFCs, and *Clostridium* (7.6%) and *Desulfovibrio* (5.1%) in the ACM-MFCs. Bacterial community in the H-MFCs was different with the single-chamber MFCs. *Pseudomonas* (12.9%) was dominated in the H-MFCs, followed by *Clostridium* (7.0%) and *Geobacter* (2.9%). For archaeal community, *Methanothrix* (96.4%) was remarkably dominated in the single-chamber MFCs. However, *Methanobacterium* (35.1%) and *Methanosarcina* (28.3%) were abundant in the H-MFCs.

### Conclusions

These results suggest that chamber design is a key factor to influence on COD removal and electricity generation in the MFCs treating MW.

**Environmental microbiology - 2**

**GENOMIC INSIGHTS INTO THE CATABOLIC VERSATILITY OF RHODOCOCCLUS SP. STRAIN P52 TOWARDS ENVIRONMENTAL POLLUTANTS**

C. Ji<sup>1</sup>, P. Peng<sup>1</sup>, H. Yang<sup>1</sup>, X. Zhang<sup>1</sup>, J. Sun<sup>1</sup>, P. Ding<sup>1</sup>, L. Li<sup>1</sup>

<sup>1</sup>*Department of Environmental Engineering,*

*School of Environmental Science and Engineering Shandong University, Jinan, China*

**Background**

*Rhodococcus* sp. strain p52, an isolated dioxin-degrader, can aerobically utilize a variety of aromatic compounds, such as dibenzofuran, dibenzo-p-dioxin, 2-chlorodibenzofuran, 2,8-dichlorodibenzofuran, dibenzothiophene, biphenyl, naphthalene, fluorene, phenanthrene, and anthracene. Degradation of dioxin by strain p52 involves two dioxygenases, DbfA and DfdA, encoded by genes on two plasmids. Additionally, strain p52 can use linear alkanes (tetradecane, tetracosane, and dotriacontane) and branched alkane (pristane) as sole carbon and energy sources.

**Objectives**

The objective of the present study is to gain insight into the underlying genetic information for the catabolic versatility, and biodegradation potential of strain p52.

**Methods**

Complete nucleotide sequence of the strain p52 genome was sequenced with the PacBio RS II system. The genome was annotated by BLAST against database, including KEGG, COG, SwissProt, TrEMBL and NR. The predicted genes involved in degradation of aromatic compounds and alkanes were tested for their transcriptional activity. And the function of the genes was confirmed by heterologous expression in recombinant hosts.

**Conclusions**

Co-presence of catabolic plasmids and multiple catabolic genes, as well as genes involved in chemotaxis, solvent tolerance, and transportation in the strain favors its catabolic ability and environmental adaptation. The present study provides insights into the bioremediation potential of strain p52.

### **BIODEGRADATION OF P-NITROPHENOL BY DIFFERENT MIXED CULTURES**

M. Ljesevic<sup>1</sup>, M. Markovic<sup>2</sup>, G. Gojgic-Cvijovic<sup>2</sup>, V. Beskoski<sup>1</sup>, M.M. Vrvic<sup>1</sup>

<sup>1</sup>Department of biochemistry, Faculty of chemistry University of Belgrade, Belgrade, Serbia

<sup>2</sup>Department of chemistry, IChTM University of Belgrade, Belgrade, Serbia

#### **Background**

One of the most important environmental pollutant among nitroaromatic compounds is *p*-nitrophenol (4-nitrophenol, PNP). It is used in the manufacture of a wide range of products and is the intermediate of some organophosphorus pesticide degradation (1). PNP has been classified as a priority pollutant by United States Environmental Protection Agency (EPA), and its concentration in natural waters is restricted to less than 10 ng/L (2).

#### **Objectives**

The aim of this study was to investigate the biodegradation of PNP by three different mixed cultures (TUS, AM and KOV) isolated from contaminated soil and sediment.

#### **Methods**

The samples were inoculated into minimal medium with increasing PNP concentrations. The biodegradation process was monitored by UV spectroscopy. The toxicity of PNP solution and PNP degradation intermediers to luminescent bacteria *Aliivibrio fischeri* was evaluated according the ISO 11348-3.

#### **Conclusions**

The mixed culture TUS showed the greatest biodegradation potential. Mixed microbial population was capable of degrading up to 100 mg/L of PNP as a sole carbon and nitrogen source. Toxicity was significantly reduced after the degradation process.

**CHARACTERIZATION OF A THERMO-STABLE BIOFLOCCULANT PRODUCED BY METHYLOBACTERIUM SP**

L.V. Mabinya<sup>1</sup>, L. Ntsaluba<sup>1</sup>, U.U. Nwodo<sup>1</sup>, A.I. Okoh<sup>1</sup>

<sup>1</sup>Biochemistry and Microbiology, University of Fort Hare, Alice, South Africa

**Background**

Chemical and organic synthetic flocculants are, currently, predominantly employed in different industrial processes such as wastewater treatment and drinking water purification. The use of bioflocculants is desirable as most chemical and organic synthetic flocculants have been shown to possess deleterious effects to human health and, also, are recalcitrant to biodegradation thus, polluting the environment.

**Objectives**

This study assessed the bioflocculant production potential of *Methylobacterium* sp. Obi isolated from Tyume River in the Eastern Cape Province, South Africa.

**Methods**

*Methylobacterium* sp. Obi (accession number HQ537130) identified through 16S rDNA and sequence BLAST analysis was evaluated for bioflocculant production and the physicochemical properties optimal for the production of bioflocculant was determined using standard technique. The bioflocculant was characterized for novelty using FTIR and thermo-gravimetric analysis.

**Conclusions**

Culture conditions for optimal production of the bioflocculant included the following: glucose as carbon source; complex nitrogen source of urea, yeast extract and (NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub>; inoculum size of 1% (v/v); initial pH 10; and 1% Ca<sup>2+</sup>. Maximum flocculating activity of 90% was attained after 36 hr of cultivation with the bioflocculant exhibiting thermal stability up to 100°C. Optimal culture conditions resulted in purified bioflocculant yield of 4.61 g/l. Optimal dose for kaolin suspension clarification 0.3 mg/ml in the presence of 1% Ca<sup>2+</sup>. Fourier transform infrared (FTIR) spectrum of the purified bioflocculant showed the presence of carboxyl, amino and hydroxyl groups known to be critical in the flocculation process. Thermo gravimetric analysis revealed that the produced bioflocculant was thermo stable.

**COMMUNITY STRUCTURE OF BENEFICIAL RHIZOBACTERIA IN APPLE ORCHARDS OF TRANS HIMALAYAN REGION AS INFLUENCED BY PHYSICAL GEOGRAPHY OF AN APPLE HILL FARM**

S. Chandel<sup>1</sup>, R. Mahajan<sup>2</sup>, A. Chauhan<sup>1</sup>, C.K. Shirkot<sup>1</sup>

<sup>1</sup>*Microbiology, Dr. Y.S. Parmar University of Horticulture and Forestry, Nauni Solan, India*

<sup>2</sup>*Biotechnology and Bioinformatics,*

*JAYPEE UNIVERSITY OF INFORMATION TECHNOLOGY (Previously at Dr. Y.S. Parmar University of Horticulture and Forestry Nauni Solan), Shimla, India*

**Background**

Over the years, diversity of beneficial rhizobacteria associated with agronomical/horticultural crops, especially the influence of geographical distribution (altitudinal variation) has been well documented. However, the influence of physical geography (eastern and western aspect of a hill farm), on the community structure of beneficial rhizobacterial population, irrespective of the altitudinal variation is unclear.

**Objectives**

The nutrient and health status of crops growing on two opposite geographical aspects of a hill farm could be influenced by presence or absence of beneficial rhizobacterial communities, with exceptional abilities of nutrient mobilization and pathogen antagonism.

**Methods**

In the present study we investigated rhizobacterial population associated with apple trees (four different apple cultivars) grown on hill farms at similar altitudes on two opposite geographical aspects. In the present study, a total of 259 rhizobacteria were isolated from the rhizosphere of apple trees, of which 50 were selected and further examined on the basis of their abilities of nutrient mobilization and pathogen antagonism. Beneficial rhizobacterial diversity analyzed using molecular analysis (16S rDNA-ARDRA) and supported by statistical tools revealed the presence of dominant siderophore producing bacterial populations (nutrient mobilizers and plant pathogen antagonists) on the eastern aspect of hill farm.

**Conclusions**

Results from microbial diversity study correlated with the survey analysis, for the presence of 40-60% of diseased apple trees and high (80-90%) non-survivability of re-planted apple plants on the western aspect of hill farm, as compared to 10-15%

diseased apple trees and low problem (15-20%) of survivability of re-planted apple plants on eastern aspect.

**Environmental microbiology - 2**

**ENTEROCOCCUS FAECIUM REDUCED MALODOROUS COMPOUNDS IN SWINE MANURE SLURRY IN VITRO AND IN CONFINEMENT HOUSES**

J. Alam<sup>1</sup>, L.L. Mamuad<sup>1</sup>, C.D. Jeong<sup>1</sup>, Y.J. Choi<sup>1</sup>, A. Biswas<sup>1</sup>, S.K. Kim<sup>2</sup>, S.S. Lee<sup>1</sup>

<sup>1</sup>Animal Science and Technology, Suncheon National University, Suncheon, Korea

<sup>2</sup>Animal Science and Technology, Konkuk University, Seoul, Korea

**Background**

Reducing malodorous compounds are still swine producers' problem.

**Objectives**

This study evaluated different bacteria for their ability to reduce malodorous compounds.

**Methods**

Previously isolated and identified bacteria with 99% similarities were used in this study. These were *Enterococcus faecium*(M1), *E. faecalis*(M2), *Acetobacter tropicalis*(M3) and *Bacillus subtilis* subsp. *subtilis*(M4). The bacteria were tested using *in vitro* technique (serum bottles and plastic boxes) and the best bacterium was selected and used as spray in the confinement pig houses.

**Conclusions**

In serum bottles technique, pH values were reduced (P<sub>3</sub>) and hydrogen sulfide (H<sub>2</sub>S) gas decreased (P and M4 from 12 to 24h while opposite was observed in NH<sub>4</sub><sup>+</sup>-N concentration in the liquid phase. Total volatile fatty acid, histamine, methylamine, ethylamine, putrescine and cadaverine as well as total biogenic amine concentration was lowest (P<sub>3</sub>, H<sub>2</sub>S, total mercaptans) and liquid NH<sub>4</sub><sup>+</sup>-N were comparatively lower (P and M4. M1 was selected and used for spray to confirm the odor reduction at different periods in the confinement pig houses. Odor compounds were lessened by 28.21%, 42.15% and 15.02% for NH<sub>3</sub>, H<sub>2</sub>S, and total amines, respectively up to 3 days after spraying. *E. faecium* can reduce malodorous compounds in swine manure slurry *in vitro* and in confinement houses.

**FEMS-1203**

**Environmental microbiology - 2**

**COMPARISON OF DIFFERENT BACTERIA ON REDUCING MALODOROUS COMPOUNDS USING IN VITRO SWINE FERMENTATION**

J. Alam<sup>1</sup>, L. Mamuad<sup>1</sup>, C.D. Jeong<sup>1</sup>, Y.J. Choi<sup>1</sup>, A. Biswas<sup>1</sup>, S.K. Kim<sup>2</sup>, S.S. Lee<sup>1</sup>

<sup>1</sup>Animal Science and Technology, Suncheon National University, Suncheon, Korea

<sup>2</sup>Animal Science and Technology, Konkuk University, Seoul, Korea

**Background**

Bacteria play a significant role in odor production.

**Objectives**

This experiment was conducted to determine the appropriate bacteria for reducing malodorous compounds during fermentation in pig.

**Methods**

The bacteria were isolated and identified from rectum of pigs and were used in this study. They have 99-100% similarities to: *Enterococcus faecium* CWBI B1430(M1), *E. faecium* DSM 20477(M2), *E. faecalis*(M3), *Lactobacillus acidophilus*(M4), *L. plantarum*(M5), *Bacillus subtilis* ZHA10(M6), *Bacillus subtilis* XJASZB15(M7), *Acetobacter malorum*(M8), and *E. faecium* NRIC0114(M9). One hundred ml of fecal slurry was transferred to serum bottles containing 1g of soluble starch, inoculated with or without 1ml of different microbial cultures ( $1.0 \times 10^7$  CFU/ml) and incubated anaerobically for 12 and 24h.

**Conclusions**

Ammonia-nitrogen (NH<sub>3</sub>-N) contents (gas phase) were decreased rapidly from 12 to 24h but was not found in M7 and M9 at 24h while NH<sub>3</sub>-N contents (liquid phase) of M6 was significantly lowest after 24h. Hydrogen sulfide (H<sub>2</sub>S) contents (gas phase) were detected in M5, M6, M7, M8 and M9. Total biogenic amine was found lowest (*P**Enterococcus faecium* NRIC 0114(M9) is the best among the all of the treatments on the basis of toxic compound production.

**Environmental microbiology - 2**

## **GRAZING BY NEMATODES AFFECTS MAIZE RHIZOSPHERIC BACTERIA**

V. Matus Acuña<sup>1</sup>, E. Martínez-Romero<sup>1</sup>

<sup>1</sup>*Ecological Genomics, Centro de Ciencias Genómicas, Cuernavaca, Mexico*

### **Background**

Both mutualistic and pathogenic bacteria colonize the plant rhizosphere. Mutualists promote plant growth by providing nutrients or defense against pathogens. Nematodes and protozoa are also enriched in the rhizosphere, but little is known about the interactions of the grazing microorganisms with the bacterial community. The diversity of protozoans and nematodes in the corn rhizosphere has't been studied and will provide a basis for the further analysis of their grazing preferences and their impact on bacteria.

### **Objectives**

Identify and isolate protozoans and nematodes from the corn rhizosphere with metagenomic and culture-dependent approaches.

### **Methods**

The diversity of the eukaryotic microorganisms was assessed analyzing 18S rRNA gene sequences from DNA extracted from corn rhizosphere samples. Nematodes were cultured in Nematode Growth Medium (NGM) and identified as described above. Feeding preferences were assayed in Petri dishes with NGM medium in the presence of different bacteria. The effect of nematodes was tested by adding the nematode to roots of maize plants growing in flasks with vermiculite.

### **Conclusions**

The metagenomic analysis was performed with DNA samples from Huitzilac in the state of Morelos and in Amecameca in the state of Puebla. In cultures, the single nematode present was identified as *Oscheius tipulae*. This nematode has a preference for the bacterium *Rhizobium phaseoli* Ch24-10, and decreases the growth of corn plants in laboratory assays. However, in the presence of a group of selected root bacteria such as *Rhizobium phaseoli*, *Methylobacterium extorquens* and *Chromobacterium violaceum*, the growth of the corn plants was enhanced compared to control plants without the nematode.

**FEMS-0942**

**Environmental microbiology - 2**

## **VIBRIO VULNIFICUS EMPLOYS DIFFERENT DEFENCE MECHANISMS AGAINST PROTOZOAN GRAZING**

P. Noorian<sup>1</sup>, S. Sun<sup>2</sup>, D. McDougald<sup>3</sup>

<sup>1</sup>*School of Biotechnology and Biomolecular Sciences,  
The University of New South Wales, Sydney, Australia*

<sup>2</sup>*Centre for Marine Bio-Innovation, The University of New South Wales, Sydney,  
Australia*

<sup>3</sup>*Singapore Centre on Environmental Life Sciences Engineering,  
Nanyang Technological University, Singapore, Singapore*

### **Background**

*Vibrio vulnificus* is an opportunistic pathogen responsible for wound infections and septicæmia following ingestion of contaminated seafood, and has the highest reported mortality rate for seafood-related diseases. It is an autochthonous inhabitant of coastal marine environments where it is exposed to predation by heterotrophic protozoa.

### **Objectives**

Protozoan predation on bacteria acts as a selective force, leading to evolution of antiprotozoal mechanisms that may also function as virulence factors. This study investigated the correlation of the place of isolation, genotype and virulence potential with grazing resistance of *V. vulnificus*.

### **Methods**

Twenty two strains of *V. vulnificus* were exposed to grazing by *Tetrahymena pyriformis*, a filter feeding ciliate, and *Acanthamoeba castellanii*, a surface browsing amoeba in microtitre plates. *V. vulnificus* numbers in planktonic phase were determined by plate counts and photometry while biofilm biomass was assessed by crystal violet staining. The health and number of protozoa were determined by microscopy.

### **Conclusions**

Although there was no significant difference in grazing resistance between C-genotype (clinical origin) and E-genotype (environmental origin), an environmental and a clinical isolates exhibited unique grazing defence mechanisms against the protozoa: the oyster isolate showed toxicity against *T. pyriformis* while the blood

isolate employed biofilm and pellicle formation to escape predation. Furthermore, the role of capsular polysaccharide (CPS) in grazing resistance of *V. vulnificus* was examined; no statistically significant differences were found between the encapsulated, 'opaque' strains and the non-pathogenic non-encapsulated, 'translucent' strains. These results show that the defence mechanisms of different strains of *V. vulnificus* have evolved along different evolutionary pathways.

## **MICROBIAL COMMUNITY DYNAMISM DURING START-UP OF ANAEROBIC DIGESTER**

M. Mellado<sup>1</sup>, E. Tapia<sup>1</sup>, G. Ruiz<sup>1</sup>, R. Chamy<sup>1</sup>

<sup>1</sup>*Escuela de Ingeniería Bioquímica, Pontificia Universidad Católica de Valparaíso, Valparaíso, Chile*

### **Background**

The start-up of anaerobic digester has not been studied in detail from the microbiological point of view. Knowledge of microbiology process could help to determine whether an anaerobic digester has reached steady state, in the event that physicochemical data are not successful.

### **Objectives**

The objective is to determine the dynamism of the microbial community during the start-up of an anaerobic digester.

### **Methods**

The start-up of two-mesophilic anaerobic digester (fed with mix sludge) was studied through methane productivity, volatile suspended solids (biomass), along with other chemical variables. The inoculum was obtained from 'La Farfana', wastewater treatment plant located in Santiago, Chile.

DNA was extracted from samples of sludge operation days 0, 13, 25 and 50. The genes studied were: 16S (*Bacteria* and *Archaea*) through DGGE and 4 functional genes (Hydrolytic, Homoacetogenic, Methanogenic and Acidogenic) through real time PCR.

### **Conclusions**

The digester reached steady state after 30 days of operation, with productivity of 140 mL methane/ (Liter day) and 40% increase in biomass.

Fig 1. Productivity of methane. The digester 1 is represented for ● and digester 2 is represented for ○

When the digesters reached the steady state the number of haplotypes (DGGE) increased about 40%, while the copies number of functional genes increased twice in

relation to the beginning of the process.

Figure 2 DGGE 16S of digester 1: (A) *Archaea* and (B) *Bacteria*

Fig 3. Copy number of hydrolytic gene during start up of two anaerobic digester  
The digester 1 is represented for ● and digester 2 is represented for ○

## MICROBIOLOGICAL SOIL QUALITY IN CITRUS ORCHARD UNDER DIFFERENT MANagements

S.P. Meneghin<sup>1</sup>, G. Vieira<sup>2</sup>, F.A. Azevedo<sup>3</sup>

<sup>1</sup>*Biologia Produção Vegetal e Animal, Universidade Federal de São Carlos, Araras, Brazil*

<sup>2</sup>*Graduanda de Bacharelado em Biologia, Universidade Federal de São Carlos, Araras, Brazil*

<sup>3</sup>*Centro de Citricultura Sylvio Moreira, Instituto Agrônomo de Campinas, Cordeirópolis, Brazil*

### Background

The inter rows of citrus orchards in Brazil are generally managed with mowing, while in the lines mainly use the herbicide glyphosate. There is a great predominance of *Urochloa decumbens* in the inter rows of orchards. As there are reports of allelopathy of *U. decumbens* to citrus and damages that result from the continued use of glyphosate in other cultures.

### Objectives

This project aims to study through microbiological parameters influences on soil quality using two vegetation in inter rows, managed with different mowing, with and without herbicide in the lines of Tahiti acid lime orchard.

### Methods

Since 2010, trial was conducted in Mogi Mirim, São Paulo State, Brazil, in split plot design, where in the plots were composed of two types of vegetation: *U. decumbens* and *U. ruziziensis*; the sub plots for two types of mowing: conventional and ecological; and the sub sub plots: by applying and absence of the herbicide glyphosate on planting line. Samples of soil from the rhizosphere of plants were collected 0-10 cm depth, in three seasons and the following parameters evaluated microbial biomass carbon (BMC), basal respiration (RB) soil and metabolic quotient.

### Conclusions

The results showed that there were significant differences for the microbiological parameters and soil treatment with *U. decumbens*, ecological mowing and herbicide use were better when compared with others. There was no damage to the vegetative and productivity development of Tahiti acid lime, so the changes in management can be recommended.

<sup>3</sup>Coastal Ecology, Alfred Wegener Institute, List, Germany

**Background**

In the framework of the BMBF-funded consortium project BIOACID (*Biological Impacts of Ocean Acidification*) we are interested in the response of marine epibacterial communities attached to biological surfaces to increased *p*CO<sub>2</sub> and temperature. In spring 2014, we performed a three-month experiment in the benthic mesocosm facility at the Alfred Wegener Institute in List (Germany) which allows low and high tide simulation to mimic Wadden Sea conditions. We manipulated the seawater *p*CO<sub>2</sub> and temperature as predicted by the end of this century to simulate ocean acidification and warming events of the future North Sea.

**Objectives**

Both stress factors were tested for single and combined effects on epibacterial communities on the surface of the brown macroalgae *Fucus vesiculosus* forma *mytili* and in comparison on the planktonic microbiota of the surrounding seawater.

**Methods**

Changes in the bacterial phylogenetic diversity were analyzed by bacterial 16S rDNA (V1-V2) amplicon sequencing using the Illumina MiSeq technology.

**Conclusions**

The generated data indicated significant shifts in the bacterial community structure over a period of three months (April to June), driven by rising temperature and lowered seawater pH levels. Overall, our findings suggest significant changes in the microbial diversity under anthropogenic pressures such as global warming and ocean acidification with potentially severe consequences for the future Wadden Sea ecosystem.

**REMOVAL OF LEAD BY PSEUDOMONAS SP ISOLATED FROM KHUZESTAN'S PETROLEUM SOILS, IRAN**

S.M. Meybodi<sup>1</sup>, H. Khorassan<sup>2</sup>

<sup>1</sup>Microbiology, IAU Sirjan Branch, Sirjan, Iran

<sup>2</sup>Microbiology, IAU Kerman Branch, Kerman, Iran

**Background**

Biosorption of heavy metals is effective technology for removal of toxic metals. Algae, bacteria and fungi are useful biosorbents for metal elimination from polluted zones.

**Objectives**

The objective of this study was isolation of lead resistant *Pseudomonas* strains.

**Methods**

Soil samples were homogenized and diluted with sterile normal saline. These samples were cultured in LB agar containing 5ppm of lead in order to isolation of resistant strains. These strains were isolated and cultured in Macconkey agar for isolation of appropriate strains and identified by metabolically tests. Maximum lead resistance of strains was evaluated by MIC test. The bacterial growth were optimized in the presence of lead in various temperatures, rate of shaking and values of pH by spectrophotometry in 600nm at 24h of cultivation. The bacterial strains were tested for ability to grow in the presence of different antibiotic by disc diffusion method. Metal adsorption test measured under optimal conditions by atomic absorption spectroscopy.

**Conclusions**

In this study 24 colonies were resistant to lead and the bacterium, *Msap*, had more resistant than others. The best conditions of growth in temperature, pH and rate of shaking were 37, 9 and 200. The results were verified using the general linear model. The highest of biosorption capacity was 91.79%. The strain, *Msap*, showed resistance to ampicillin, tetracycline, chloramphenicol, erythromycin, and kanamycin. *Msap*, have a great potential for bioremoval of lead from aquatic polluted environments. In conclusion, this study reveals the significance of using the *Pseudomonas* sp in bioremediation of lead contaminated zones.

**Environmental microbiology - 2**

## **CHARACTERIZATION OF BIOAEROSOLS - VALIDATION OF A REDUCED SAMPLING METHOD -**

S. Michael<sup>1</sup>, N. Nowak<sup>1</sup>, W. Dott<sup>1</sup>

<sup>1</sup>*Institute of Hygiene and Environmental Medicine, RWTH Aachen University, Aachen, Germany*

### ***Background***

Bioaerosol monitoring is a rapidly increasing field of environmental risk assessment, which includes measurement of different microbiological and chemical parameters in both indoor and ambient air. Generally, bioaerosols are particles of biological origin with an aerodynamic diameter of up to 100 nm, containing bacteria, fungi, viruses, pollen, plant debris as well as their metabolites like endo-/mycotoxins, allergens and (M)VOC's. In the last years, numerous studies showed associations between biological particles and a wide range of adverse health effects such as infections, intoxication and sensitization.

### ***Objective***

The aim of the study was the validation of a reduced and optimized sampling procedure necessary for a comprehensive bioaerosol risk assessment.

### ***Methods***

We investigated bioaerosols from laying hen-, swine- and cattle livestock on different measuring sites (within the barn, 50 m downwind and background) using impaction and impingement. For the microbiological testing the total viable count of bacteria and fungi as well as a selective enrichment for MRSA, ESBL and VRE was carried out. Additional species identification (bacteria/ fungi) was performed by MALDI-TOF-MS. The chemical characterization included the detection of particulate matter (PM<sub>10</sub>, PM<sub>2.5</sub>, PM<sub>1</sub>, UFP), endotoxin, metal and VOC content.

### ***Conclusion***

The interspecies comparison show clear variation in the microbiological (bacterial/ fungal) and chemical components (PM, endotoxin and (M)VOC level) profile between the livestock (indoor). Up to 50 m downwind no differences compared to the background samples of the corresponding livestock were detected. Due to the harmonized combination of selected chemical and microbiological indicator parameter, the reduced sampling program constitutes a constructive alternative for a comprehensive risk assessment.

## **ISOLATION AND IDENTIFICATION OF CYANIDE TOLERANT BACTERIA FROM WASTEWATER DISCHARGED FROM AN ELECTROPLATING PLANT IN CAPE TOWN, SOUTH AFRICA**

M. Mobo<sup>1</sup>, V.A. Jackson<sup>1</sup>, A.N. Paulse<sup>1</sup>, S.K.O. Ntwampe<sup>1</sup>

<sup>1</sup>Bioresource Engineering Research Group,  
Cape Peninsula University of Technology, Cape Town, South Africa

### **Background**

The pollution of water sources is one of the major challenges municipalities face worldwide. The industrial wastewater discharged into the municipal sewers often contain toxic substances. Electroplating industries contribute to the pollution of water sources with cyanide, cyanide metal complexes and heavy metals used in their metal plating processes.

### **Objectives**

The aim of this study was therefore to isolate and identify cyanide tolerant bacteria from wastewater discharged from an electroplating plant in the Western Cape, South Africa which was suspected of disposing of its potentially hazardous wastewater into the municipal sewers.

### **Methods**

Bacteria were isolated from the biofilm and wastewater discharged from the electroplating plant. The pure colonies were streaked on nutrient agar supplemented with 400 mg/L cyanide to test for tolerance. To characterise and identify the cyanide tolerant isolates the following tests were performed; gram and endospore staining, biochemical tests, selective media, VITEK 2 Compact, Genomic DNA extraction, Polymerase chain reaction (16s rRNA gene amplification) and sequence analysis.

### **Conclusions**

Two of the isolates were identified as *Pseudomonas* species and the other two as *Bacillus* species. The four identification methods used (biochemical testing, selective media, VITEK 2 and sequence analysis (16s rRNA gene) could confirm 100% identity up to the genus level even though a few discrepancies in identifying the species existed. Further studies are however needed to study other genes to differentiate the species. The isolates are further to be tested for cyanide degradation and as possible candidates for bioremediation of cyanide and metal cyanide complexes.

**Environmental microbiology - 2**

## **MYXOBACTERIA IN PEAT BOGS AND FEN – AN ASTONISHING DIVERSITY**

K.I. Mohr<sup>1</sup>, T. Zindler<sup>1</sup>, J. Wink<sup>1</sup>

<sup>1</sup>*Microbial Strain Collection, Helmholtz Centre for Infection Research, Braunschweig, Germany*

### **Background**

Increasingly appearing resistances to antibiotics and the subsequent need for new bioactive substances is one of the fundamental challenges of infection research. Myxobacteria have a rich secondary metabolism, which places them among the best known natural product producers. To date more than 100 new metabolites and more than 500 derivatives were described from these soil dwelling, predatory microorganisms. In the past it turns out that in particular new families, genera and species of myxobacteria are reliable sources for new compounds.

### **Objectives**

Promising sources for the isolation of new myxobacteria are uncommon habitats like, for example, peat bogs or fen, which are characterized by low pH values. This habitat has been neglected with regard to the isolation of myxobacteria in the past. In our study, the diversity of myxobacteria in moor-samples from the Harz-region was evaluated by standard cultivation methods as well as by cultivation independent 16S rRNA-clone bank analyses.

### **Methods**

A total of 297 clones of myxobacterial origin were sequenced and compared to sequences of cultures, isolated from these samples, by phylogenetic analyses. It turned out that the majority of myxobacteria is only represented by clone sequences and could not be cultivated. Comparing these sequences to sequences of a public database (NCBI) revealed that most of these uncultivated myxobacteria are exclusively related to other uncultivated myxobacterial sequences from acidic soils.

### **Conclusions**

This suggests that peat bogs and fen harbor a big diversity of new myxobacterial species, genera and even families which themselves harbor a great potential of urgently needed, new secondary metabolites.

**FEMS-3032**

**Environmental microbiology - 2**

## **EVOLUTIONARY HISTORY INFLUENCES THE SALINITY PREFERENCE OF BACTERIAL TAXA IN WETLAND SOILS**

E. Morrissey<sup>1</sup>, R. Franklin<sup>2</sup>

<sup>1</sup>*Center for Ecosystem Science and Society, Northern Arizona University, Flagstaff, USA*

<sup>2</sup>*Department of Biology, Virginia Commonwealth University, Richmond, USA*

### **Background**

Salinity is a major driver of phylogenetic bacterial community composition across the globe and, given the importance of microbial community composition for ecosystem function, it is necessary to understand how salinity structures bacterial communities. If phylogenetic groups exhibit coherence in their salinity preferences, characterizing these preferences will enhance our ability to predict how changes in salinity will affect microbial communities and their associated functions.

### **Objectives**

Consequently, we aimed to examine the response of wetland bacterial community composition and function to changes in salinity and to assess whether salinity preferences were phylogenetically conserved in bacteria.

### **Methods**

To address these aims, we used a reciprocal transplant experiment of fresh- and saltwater wetlands soils.

### **Conclusions**

The salinity of both the origin and host environments affected bacterial community structure (16S rRNA gene sequences, Illumina) and activity (e.g., CO<sub>2</sub> and CH<sub>4</sub> production). Phylotypes were categorized as exhibiting a preference for freshwater, saltwater, or having no salinity preference by comparing presence/absence patterns across treatments. When these preferences were related to phylogeny, a significant influence of evolutionary history was seen in all preference categories. This phylogenetic signature was corroborated by differences in the salinity preferences of high-level taxonomic groups. The majority of  $\alpha$ -proteobacteria and  $\gamma$ -proteobacteria phylotypes preferred saltwater, while the phylotypes of  $\beta$ -proteobacteria were more likely to prefer freshwater, and phylotypes within Verrucomicrobia tended to have no salinity preference. Overall, our results indicate that salinity structures bacterial communities by selecting for organisms with phylogenetically clustered salinity preferences, and these effects on community composition may have consequences for ecosystem function.

**Environmental microbiology - 2**

**METABOLIC PATHWAY INVOLVED IN H<sub>2</sub> PRODUCTION FROM FORMATE BY  
DESULFOVIBRIO VULGARIS**

C. Mourato<sup>1</sup>, M. Martins<sup>1</sup>, J. Voordouw<sup>2</sup>, G. Voordouw<sup>2</sup>, I. A.C. Pereira<sup>1</sup>

<sup>1</sup>Universidade Nova de Lisboa,

Instituto de Tecnologia Química e Biológica António Xavier, Oeiras, Portugal

<sup>2</sup>Department of Biological Sciences, University of Calgary, Calgary, Canada

**Background**

Formate is an important metabolite in anaerobic environments, where it is one of the metabolic products of fermentative organisms and an energy source for many bacteria such as sulfate-reducing bacteria (SRB). SRB are anaerobic organisms that possess a high number of formate-dehydrogenases (FDHs) and hydrogenases (Hases), enzymes responsible for H<sub>2</sub> production from formate [1]. In sulfate-limited environments SRB grow fermentatively in syntrophy with other organisms producing H<sub>2</sub>. Moreover, it was recently demonstrated that in the absence of sulfate, *Desulfovibrio vulgaris* displays a very high H<sub>2</sub> production from formate [2].

**Objectives**

In the present work, the electron transfer mechanism involved in formate-driven H<sub>2</sub> production by SRB was studied.

**Methods**

H<sub>2</sub> production by *D. vulgaris* deletion mutants of the two main FDHs ( $\Delta fdhABC_3$  and  $\Delta fdhAB$ ) and of the four periplasmic Hases (Fe-only Hase ( $\Delta hydAB$ ), two [NiFe] Hase ( $\Delta hynAB1$  and  $\Delta hynAB2$ ), and a [NiFeSe] Hase ( $\Delta hysAB$ )) was compared with the wild-type strain in order to disclose the role of each enzyme in the metabolic pathway involved in H<sub>2</sub> production from formate [3].

**Conclusions**

This work contributes to our knowledge about the electron transfer pathways involved in H<sub>2</sub> and formate metabolism in *D. vulgaris*, showing which of the FDHs and Hases play an important role in this process.

**BACTERIAL PROFILING OF SAHARAN DUST DEPOSITION IN THE ATLANTIC OCEAN USING SEDIMENT TRAP MOORINGS – YEAR ONE RESULTS**

C. Munday<sup>1</sup>, G.J.A. Brummer<sup>1</sup>, M. van der Does<sup>1</sup>, L. Korte<sup>1</sup>, J.B.W. Stuut<sup>1</sup>

<sup>1</sup>*Geological and Chemical Oceanography,  
Netherlands Institute for Sea Research (NIOZ), 't Horntje, Netherlands*

**Background**

Large quantities of dust are transported from the Sahara Desert across the Atlantic Ocean towards the Caribbean each year, with a large portion of it deposited in the ocean. This dust brings an array of minerals, nutrients and organic matter, both living and dead. This input potentially fertilizes phytoplankton growth, with resulting knock-on effects throughout the food chain. The input of terrestrial microbial life may also have an impact on the marine microbial community.

**Objectives**

The aim is to understand the links between dust input and the bacterial community and how this relates to ocean productivity and the carbon cycle.

**Methods**

The current multi-year project consists of a transect of floating dust collectors and sub-surface sediment traps placed at 12°N across the Atlantic Ocean. Sediment traps are located 1200m and 3500m below the sea surface and all are synchronized to collect samples for a period of two weeks.

**Conclusions**

The first set of sediment trap samples were recovered using the *RV Pelagia* in November 2013 with promising results. Results from 7 sediment traps (three at 1200m and four at 3500m) were obtained. In general, the total mass flux decreased as distance from the source increased and the upper traps generally held more material than those at 3500m. Denaturing Gradient Gel Electrophoresis (DGGE) was used as a screening technique, revealing highly varied profiles, with the upper (1200m) traps generally showing more variation throughout the year. Preliminary analysis of 454 sequencing from a subset of the samples supports this observation, and detailed analysis will be presented.

**ISOLATION AND IDENTIFICATION OF BIOAEROSOLS SAMPLED BY PM2.5 FILTERS USED IN NETWORK MONITORING AIR QUALITY ABURRA VALLEY, MEDELLÍN - COLOMBIA**

D. Nanclares<sup>1</sup>, D.A. Grajales<sup>2</sup>, L.F. Gaviria<sup>1</sup>, O.I. Campuzano<sup>2</sup>, C.E. Zapata<sup>1</sup>

<sup>1</sup>Facultad de Minas, Universidad Nacional de Colombia, Medellín, Colombia

<sup>2</sup>Facultad de Ciencias, Universidad Nacional de Colombia, Medellín, Colombia

**Background**

By the recent years, it has increased the air pollution in urban environments as well as rural, due to anthropogenic activities. This has been reflected on respiratory illness or infections related to air pollutants, mainly to fine inhalable particulate matter PM2.5; nonetheless, it is rarely discussed in the aburra valley about the microorganisms associated to this sort of particles, which can cause human illness ranging from mucosa irritation and allergies to asthma and pneumonia.

**Objectives**

The purpose of this research is the isolation and identification of microorganisms present in PM2.5 filters of the stations MED-UNFM and MED-PJIC of the Air Quality Monitoring Network from the Aburrá Valley

**Methods**

Air sampling equipment BGI PQ200 semiautomatic was used for collection of biological material in PM2.5 Teflon filters 47mm in diameter. A sample of the latter was inoculated and incubated in an enrichment broth; Serial dilutions were made and were inoculated onto selective media. Each of the strains isolated, were characterized morphologically and biochemically (VITEK® 2 Compact).

**Conclusions**

In this research, several microbial species from PM2.5 filters, were isolated and identified like *Bacillus cereus*, *Acinetobacter baumannii*, *Enterococcus faecium* and *Bacillus anthracis*, all those consider as pathological microorganisms. This allows inferring that air quality, besides generating problems associated to respiratory illness, can increase the possibility of contracting bacterial infections.

**METAL-RICH TROPICAL SEDIMENT MICROBIOME UNVEILS A DIVERSE TAXONOMIC AND FUNCTIONAL MICROBIAL COMMUNITY**

P.S. Costa<sup>1</sup>, M.P. Reis<sup>1</sup>, M. Ávila<sup>1</sup>, L.R. Leite<sup>2</sup>, F.M.G. Araújo<sup>2</sup>, A.C.M. Salim<sup>2</sup>, G. Oliveira<sup>2</sup>, F. Barbosa<sup>1</sup>, E. Chartone-Souza<sup>1</sup>, A.M.A. Nascimento<sup>1</sup>

<sup>1</sup>*Biologia Geral, Universidade Federal de Minas Gerais, Belo Horizonte, Brazil*

<sup>2</sup>*Cebio, Centro de Pesquisas René Rachou Fundação Oswaldo Cruz, Belo Horizonte, Brazil*

**Background**

The Iron Quadrangle (Minas Gerais, Brazil) is one of the world's largest mining regions, being historically explored for over 300 years. Since then, many toxic metals and metalloids were released into the environment leading to contamination of water bodies. It is well known that microbial community influences the bioavailability of these toxic elements and its importance in the ecological balance of various environments.

**Objectives**

This study investigated the taxonomic and functional diversity of the microbiome from Mina Stream sediment (MSS), historically metal-contaminated, especially arsenic.

**Methods**

The environmental DNA extracted was sequenced using SOLiD and Miseq platforms for the functional and taxonomic analysis, respectively.

**Conclusions**

Taxonomic profile obtained by Greengenes database revealed a complex microbial community, with dominance of *Proteobacteria* and *Parvarcheota*. Contigs recruited bacterial and archaeal genomes, especially *Candidatus Nitrospira defluvii* and *Nitrosopumilus maritimus*, and their presence implicated them in C and N cycling in the MSS. Functional reconstruction revealed a large diverse set of genes for ammonium assimilation and ammonification. These processes have been implicated in the maintenance of N cycle and healthy of the sediment. SEED subsystems functional annotation unveiled a high diversity of metal resistance genes, suggesting that the prokaryotic community is adapted to metal contamination. Furthermore, a high metabolic diversity was detected in MSS, suggesting that the historical arsenic contamination is no longer affecting it. Finally, the results reported herein may contribute to expand the current knowledge of the microbial taxonomic and functional composition of tropical metal-contaminated freshwater sediments.

**BIODEGRADATION OF AN ORGANOPHOSPHATE, CHLORPYRIFOS BY MICROBES ISOLATED FROM AGRICULTURE SOIL**

T. Nayak<sup>1</sup>, T.K. Adhya<sup>1</sup>, M. Suar<sup>1</sup>, V. Raina<sup>1</sup>

<sup>1</sup>*KIIT School of Biotechnology, KIIT University, Bhubaneswar Orissa, India*

**Background**

Organophosphorous Pesticides (OP) are being used for pest control in many countries. Extensive use of these compounds results in their accumulation in agricultural soil, water source, affecting insects and humans. Chlorpyrifos (CP) a broad-spectrum insecticide has been used for controlling termites, beetles on paddy fields and vegetable crops. CP acts as a neurotoxin by inhibiting acetylcholinesterase, which degrades the neurotransmission agent, acetylcholine, in the nervous system. Biodegradation of CP results in the formation of a compound TCP (3,5,6-trichloro-2-pyridinol) classified as mobile, toxic also has antimicrobial property.

**Objectives**

Screening, isolation and identification of the microbial isolates for Chlorpyrifos and TCP degradation

**Methods**

Resting cell assay for Chlorpyrifos degradation in liquid media and HPLC analysis

**Conclusions**

Present investigation showed microbial strains isolated and screened from agricultural soil amended with CP. Six bacterial strains (CPD-03, CPD-5C, CPD-7, CPD-18, CPD-20 & CPD-33) showed significant degradation of CP in minimal salt media supplemented with CP @ 10 µg/ml. A resting cell assay was carried out at pH 7.2, 37 °C with CP @ 10 µg/ml and monitored over a period of 48 h, and analyzed using HPLC. The degradation efficiency of these isolates varied between 65% to 67% within 48 h. The isolates CPD-18, CPD-20 and CPD-33 were able to degrade CP and metabolize TCP up to 64% - 65 % within 48 hr compared to CPD-03, CPD-5C, CPD-7 which degraded up to 65% - 67%. These six microbial strains can extend our understanding of pesticide degradation and would be beneficial in using as a consortium for cleaning up pesticide contaminated environment.

**PREVALENCE AND ANTIBIOGRAM PROFILING OF ESCHERICHIA COLI PATHOTYPES RECOVERED FROM TYUME RIVER IN THE EASTERN CAPE PROVINCE OF SOUTH AFRICA**

A. Okoh<sup>1</sup>, S. Koba<sup>1</sup>, N. Mkwetshana<sup>2</sup>

<sup>1</sup>SA-MRC Microbial Water Quality Monitoring Center University of Fort Hare, University of Fort Hare, Alice, South Africa

<sup>2</sup>Biochemistry and Microbiology, University of Fort Hare, Alice, South Africa

**Background**

Waterborne diseases are among the leading causes of morbidity and mortality in developing countries and diarrheagenic *Escherichia coli* are one of the most important etiologic agents of acute diarrhea and represent a major public health problem in developing countries like South Africa.

**Objectives**

In this study, we assessed the prevalence and antibiogram profiles of *E. coli* pathotypes in Tyume River South Africa.

**Methods**

Twelve water samples were collected from three sites along the rivers between August 2010 and July 2011 and *E. coli* was isolated by the membrane filtration method on mFC and Chromocult agar. Identification and pathotyping of the isolates were done by polymerase chain reaction technique using species/pathotype specific primers and antibiogram was conducted using the disk agar diffusion method.

**Conclusions**

Of the 202 presumptive *E. coli* isolates recovered from the river 35% were confirmed as *E. coli*. The pathotypes prevalence was as follows: ETEC (30%); EPEC (35%); EAEC (35%); and EIEC (16%). All five *E. coli* pathotypes showed high-level resistance to ampicillin, tetracycline, cotrimoxazole, and chloramphenicol but were highly susceptible to quinolones, aminoglycosides, and novobiocin. All the EAEC, ETEC, and EIEC pathotypes were resistant against ampicillin, while 87.5% of the EAEC pathotype were resistant to carbenicillin. Also, all the pathotypes were susceptible to quinolones. *TEM* genes and integron conserved segments were observed in 80% of the isolates. The Tyume river appears to be a reservoir of pathogenic *E. coli* strains and antibiotic resistance determinants, and hence a subject of public health importance.

**Environmental microbiology - 2**

**PHYLOGENETIC CHARACTERIZATION AND COMMUNITY DIVERSITY OF  
HYDROCARBON-DEGRADING BACTERIAL POPULATIONS IN SOIL  
MICROCOSMS ENRICHED WITH VARIOUS AROMATIC HYDROCARBONS**

O. Ola<sup>1</sup>

<sup>1</sup>*Biology & The Center For Sustainability and The Environments, Albion College,  
Albion, USA*

**Background**

High quantities of various aromatic hydrocarbons such as toluene, benzene, ethylbenzene and xylene {BTEX} are ubiquitously found in nature as a result of both natural and anthropogenic influences. Despite previous research efforts devoted to understanding the degradation of hydrocarbon pollutants in various environments, yet, there is still paucity of knowledge concerning the diversity of indigenous bacterial populations that are mostly responsible for the biodegradation of various hydrocarbons.

**Objectives**

The primary focus of this study was to isolate and characterize indigenous bacterial populations in soil microcosms previously enriched with various aromatic {BEX} hydrocarbons. Also, to compare the diversity of hydrocarbon degraders between the three microcosm communities examined.

**Methods**

Combinations of standard microbiological {phenotypic} and molecular {16S ribosomal RNA gene sequencing} were used to isolate, characterize and identify 45 bacterial isolates with putative hydrocarbon-degrading capability in the three soil microcosms. Additionally, various bioinformatics and analytical tools were employed for sequence alignments and diversity measurements.

**Conclusions**

A total of 45 bacterial isolates belonging to 5 distinct phyla were phylogenetically characterized among indigenous bacterial populations with putative hydrocarbon-degrading in the soil microcosms. In general, bacterial members of the  $\gamma$ -proteobacteria {mostly *Pseudomonas* and *Acinetobacter*} dominated {between 60 to 94%} among the isolates from the three microcosms. Bacterial members belonging to the  $\beta$ -proteobacteria {*Comamonas* and *Delftia* sp} and Firmicutes {*Bacillus* sp} were also represented. Overall, the differences observed in bacterial phylotypes among the microcosms are probably attributable to the direct effects of the chemical properties of each hydrocarbon pollutant on the indigenous microbial community.

## **NOSOCOMIAL INFECTIONS IN NIGERIA: A CASE STUDY FROM DELTA STATE, NIGERIA**

A.N. Oli<sup>1</sup>, C.C. Ekejindu<sup>1</sup>, D.U. Adje<sup>2</sup>, C.C. Okoli<sup>1</sup>

<sup>1</sup>*Department of Pharmaceutical Microbiology and Biotechnology,  
Nnamdi Azikiwe University, Agulu, Nigeria*

<sup>2</sup>*Department of Clinical Pharmacy and Pharmacy Administration Faculty of Pharmacy  
, Delta State University Abraka, Abraka, Nigeria*

### **Background**

Nosocomial or hospital acquired infections (HAIs) is a serious global public health issue, causing the suffering of about 1.4 million people across the world at any given time

### **Objectives**

This study was undertaken to ascertain the prevalence of HAI in Delta State of Nigeria.

### **Methods**

This is a descriptive case study design in which structured questionnaire was administered to 96 doctors, 170 nurses, 24 pharmacists and 40 medical laboratory scientists from randomly selected government hospitals and 90 doctors, 180 nurses, 30 pharmacists and 30 medical laboratory scientists from randomly selected private hospitals, all located in the 25 Local Government Areas of Delta State. The study was carried out between May and July 2013 after Ethical Approval was granted by the Ministry of Health, Delta State.

The commonest HAIs encountered are Urinary Tract Infection (61.4%) followed by Hospital acquired Pneumonia (55.6%) and Staphylococcus aureus (54.4%) for the government hospitals. In the private sector, Hospital acquired Pneumonia (66.1%) is the commonest. The study also showed that the frequency of occurrence of HAI is higher in government than private hospitals. This can be attributed to the higher population of patients leading to overcrowding. The modes of transmission of hospital acquired pneumonia was observed to follow this order airborne > contact with blood and body fluids > contaminated instruments > contaminated hands > needle sticks.

### **Conclusions**

The prevalence of nosocomial infection in this state is very high. Efforts are needed to reduce it, improve the quality of life of patients and healthcare workers and improve healthcare delivery.

**FEMS-1055**

**Environmental microbiology - 2**

**BACTERIAL BIODIVERSITY IN THE RICE RHIZOSPHERE AND HIGH-SALT SOIL AND SEDIMENT ENVIRONMENTS FROM THE CAMARGUE REGION (FRANCE)**

J. Osman<sup>1</sup>, M. DuBow<sup>1</sup>

<sup>1</sup>Microbiologie,

*Institut de Biologie Interactive de la Cellule (I2BC) CEA CNRS Université Paris-Saclay, Orsay, France*

**Background**

The Camargue territory in the south of France is a delta triangle of 1500 km<sup>2</sup> of the Rhône River as it flows into the Mediterranean. This zone consists mostly of salty land inhabited by a diverse community of birds, wild white horses, black bulls and waterfowl, the most famous of which are pink flamingos. Rice production covers approximately 10,000 hectares which accounts for 30 percent of France's rice consumption.

**Objectives**

We are examining the microbial composition of high salinity salt ponds, soils and the rhizosphere of rice plants in the Camargue region for two consecutive years (2013-2014) in order to establish a variable-temporal comparison regarding the physical and chemical properties of the environment versus the bacterial communities present in similar (saline) environments.

**Methods**

Bacterial biodiversity of five rhizosphere sites, growing two varieties of rice (Arelate and Gageron), plus sixteen sites of sediments and soils from nearly saline wetlands, were studied using pyrosequencing of PCR-amplified 16S V3-V4 rDNA amplicons from total extracted genomic DNA.

**Conclusions**

Our preliminary results revealed bacterial populations dominated by members of the *Bacteroidetes* and *Proteobacteria* phyla. However, in sandy soils with a lower degree of salinity than the 25 ppm, we observed, members from the *Acidobacteria* phylum representing an important fraction. Ongoing analyses of diversity (Chao1, Shannon and Simpson index) and statistics such as principal component analyses (PCA) will permit a detailed description of the bacterial populations among the different sampling sites, and better comparisons with similar types of sites worldwide.

## **INVESTIGATION OF AEROBIC HETEROTROPHIC BACTERIA IN OIL RESERVOIRS IN THE SOUTHEAST ANATOLIA REGION**

N. Öz<sup>1</sup>, A. Çotuk<sup>1</sup>, E. Sungur<sup>1</sup>

<sup>1</sup>*Department of Basic and Industrial Microbiology, İstanbul University, İstanbul, Turkey*

### **Background**

Petroliferous soil has unique environment due to the presence of a variety of aliphatic and aromatic hydrocarbons, creating a distinctive habitat for certain microbial communities. Although hydrocarbons are constituted only of two elements, relative to their electron acceptors; they are exploited as growth substrates by numerous microorganisms. Some aerobic bacteria, especially *Pseudomonads* are one of the most frequently isolated bacteria from hydrocarbon-impacted environments due to their reported metabolic pathways.

### **Objectives**

The aim of this study was to determine the presence, abundance and the predominant culturable aerobic heterotrophic bacteria as well as *Pseudomonads* in 4 different production wells located in the Southeast Anatolia Region.

### **Methods**

Petroleum samples were warmed to 40-60°C for a few hours until water-phase could be observed under oil phase. Diluted water-phase samples were inoculated onto Nutrient Agar, Tryptone Soy Agar, R2A, Cetrimid Agar and Pseudomonas Agar Base with and without salt. Petri plates were incubated at 30°C for 2 days (R2A for 5 days). Genomic DNA was extracted from the pure cultures using UltraClean Microbial DNA Isolation Kit. 16S rDNA gene fragments were amplified using U968F and L1401R primers. The amplified gene fragments were subsequently analyzed using sequencing.

### **Conclusions**

It was determined that the number of aerobic heterotrophic bacteria and *Pseudomonads* was generally low/high (min. 9 cells/ml and max. 1358 cells/ml) in the oil reservoirs. 15 pure cultures were obtained from the samples. Among the cultured bacteria, *Acinetobacter guillouiae* (99.3%), *Halomonas daqingensis* (99.7%), *Suttonella indologenes* (93.1%) and *Pseudomonas stutzeri* (99.8%) were present.

**Environmental microbiology - 2**

**EVALUATING THE RELATIVE INFLUENCE OF BIOTIC AND ABIOTIC FACTORS  
ON EFFICIENCY OF BIOAUGMENTATION MEDIATED EX-SITU  
BIOREMEDIATION**

J. Pandey<sup>1</sup>

<sup>1</sup>*Department of Biotechnology, Central University of Rajasthan, Kishangarh, India*

**Background**

Soil and ground water pollution with xenobiotic chemicals is a major environmental concern. Bioremediation has been regarded as an efficient and environment friendly approach for restoration of contaminated niches. Amongst different bioremediation procedures, bioaugmentation is considered as one of the most potent approach for bioremediation. However, till date very few reports have shown successful application of this approach. It is often suggested that variety of biotic and abiotic factors e.g. indigenous microbial community, physico-chemical nature of contaminating pollutant and target soil may influence the efficiency and outcome of bioaugmentation process.

**Objectives**

To systematically address this issue, we performed a study for determination of relative influence of biotic and abiotic factors on efficiency of *p*-nitrophenol (PNP) degradation during bioaugmentation mediated *ex situ* bioremediation.

**Methods**

PNP degradation was monitored in microcosms prepared with soil samples collected from seven geographically distinct Indian provinces (viz., Assam, Andhra Pradesh, Gujarat, Karnataka, Maharashtra, Rajasthan and Tamil Nadu) having diverse physico-chemical character and native microbial communities. Soil samples were spiked with 70 ppm of PNP and subjected to bioaugmentation using pre-grown cells of degradative strain.

**Conclusions**

Quantification of residual PNP showed apparent enhancement of pollutant degradation; however, kinetics of pollutant removal varied significantly as a function of soils properties. Results from statistical analysis of PNP degradation patterns and matrices generated with microbial community and physico- chemical characteristic of soil highlighted relatively strong influence of indigenous bacterial community on biodegradation efficiency. It was observed that soil microbial community renders such impact by differentially modulating the survival of bioaugmented strain.

**AN O-NITROBENZOATE (ONB) SENSITIVE TRANSPOSON MUTANT OF ARTHROBACTER PROTOPHORMIAE STRAIN RKJ100 INDICATES FOR INVOLVEMENT OF N-ACETYLGLUCOSAMINIDASE IN BACTERIAL RESISTANCE TOWARDS ITS ELEVATED CONCENTRATIONS**

J. Pandey<sup>1</sup>

<sup>1</sup>*Department of Biotechnology, Central University of Rajasthan, Kishangarh, India*

**Background**

Microorganisms capable of thriving under extreme environments are of great significance for basic as well as applied studies. Consequently, microorganisms showing survival under extreme environments have attracted considerable interest. Several studies have shown isolation and characterization of extremophilic microorganism. However, relatively fewer studies have reported isolation and characterization of microorganisms from niches characterized by elevated concentration of anthropogenic, xenobiotic environment pollutants. Previously we had characterized *Arthrobacter protophormiae* RKJ100 for its ability to tolerate extremely high concentrations of o-nitrobenzoate (ONB), a toxic xenobiotic environmental pollutant.

**Objectives**

Main objective of present study was to characterization of gene(s)/ gene cluster(s) involved in resistance of strain RKJ100 towards elevated concentrations of ONB.

**Methods**

Random transposon mutants of strain RKJ100 were generated and screened for ONB sensitive phenotype. A sensitive mutant was defined as one which exhibits sensitivity towards ONB at  $\geq 30$  mM. Molecular and biochemical characterization of this mutant was carried out to identify the gene disrupted due to the transposition.

**Conclusions**

Results from the characterization of ONB sensitive mutants showed disruption of endo- $\beta$ -N-acetylglucosaminidase (ENGase) gene. ENGase is a non-essential enzyme involved in oligosaccharide processing and cell wall recycling many life forms. It has been shown to have role in cellular homeostasis. Results obtained

during this study present first evidence for its role in bacterial resistance towards elevated concentrations of toxic xenobiotic compound.

**BIODEGRADATION OF BISPHENOL A-LIKE ENDOCRINE DISRUPTORS BY DIVERSE MICROORGANISMS FROM RIVER SEDIMENT**

Y.H. Peng<sup>1</sup>, Y.J. Chen<sup>1</sup>, Y.J. Chang<sup>1</sup>, C.A. Tan<sup>1</sup>, Y.H. Shih<sup>1</sup>

<sup>1</sup>Department of Agricultural Chemistry, National Taiwan University, Taipei, Taiwan

**Background**

Bisphenol A (BPA) is a widely used chemical in the production of plastics and resins. Tetrabromo-BPA (TBBPA), the BPA derivatives with bromide atoms, is one of the most commonly used brominated flame retardants. The broad distribution of BPA-like pollutants in the environment raises great concern because of their endocrine-disrupting characteristics and toxicity.

**Objectives**

Developing cheap and low environmental impact remediation methods for BPA-like pollutants is emergent. Therefore, the biodegradation abilities of diverse microorganisms toward BPA and TBBPA were investigated.

**Methods**

The microcosm from acclimated sediment culture was used to evaluate the biodegradation ability of diverse microorganisms and isolate pure degraders.

**Conclusions**

The microcosm completely removed BPA (10 mg L<sup>-1</sup>) within 28 h and transformed the contaminant into several metabolic intermediates. During the degradation process, the microbial composition fluctuated and finally restricted to *Pseudomonas knackmussii* and *Methylobacterium clara*. The four isolated BPA degraders were all genetically similar to *P. knackmussii*. Although the degradation ability of mixed strains was higher than that of single strain, it was far less than that of the original microcosm. These results demonstrated the novel role of *P. knackmussii* in BPA degradation, as well as the crucial role for microbial diversity in pollutant decomposition. From the acclimated sediment culture, a novel TBBPA degrader was isolated. It degraded 70 % of the pollutant (4 mg L<sup>-1</sup>) within 5 days and transformed the pollutant to one degrading by-product. Our results are helpful to understand the natural attenuation processes of BPA-like endocrine disruptors, as well as to remediate those structural similar pollutants.

## **PRESENCE OF *P. SHIGELLOIDES* IN TEMPERATE CLIMATE ZONE LAKES**

M. Petrusic<sup>1</sup>, V. Aleksic<sup>1</sup>, A. Petrovic<sup>1</sup>, D. Obreht<sup>1</sup>, M. Tomic<sup>1</sup>, P. Knezevic<sup>1</sup>

<sup>1</sup>Department of biology and ecology, Faculty of Sciences-University of Novi Sad, Novi Sad, Serbia

### **Background**

*Plesiomonas shigelloides* is a Gram-negative rod-shaped bacterium found in aquatic environments. Most of the reports on its isolation are from tropical or subtropical areas. Furthermore, the bacterium is considered as an emerging opportunistic pathogen.

### **Objectives**

Aim of this study was to detect presence of *P. shigelloides* in lakes situated in temperate climate zone (Central Europe).

### **Methods**

Total of 42 water samples taken from Vojvodina, i.e. northern Serbia and southern Hungary lakes were examined. Some samples were taken from same locations but at different time intervals, so all isolates were obtained from geographically and/or chronologically different sources. The samples were spread directly onto Inositol Brilliant Green Bile Agar and incubated at 37 °C for 24 hours. The colonies of inositol fermenting bacteria were randomly selected, subcultivated and several preliminary tests were performed (Gram staining, catalase and oxidase test, indol production, gelatin hydrolysis and citrate utilization test). *P. shigelloides* was additionally characterized and identification was confirmed by PCR using specific primers (Ref, god). Additionally, RAPD analysis was performed to estimate genetic relationships among the isolates using 5 different primers.

### **Conclusions**

The results indicate the frequent presence of bacteria in the waters in moderate climate, since *P. shigelloides* was isolated from 81% of the samples. RAPD analysis revealed distinct DNA fingerprint patterns for each *P. shigelloides* strain. The results confirm high presence of *P. shigelloides* in temperate climate zone lakes in Central Europe, which is probably a result of global climate changes. In addition, *P. shigelloides* can represent a potential health concern in this region.

## **THE SOIL MICROBIOME: INFLUENCE OF THE DECADES-LASTING INDUSTRIAL PRODUCTION OF BETA-LACTAM ANTIBIOTICS**

M. Plačková<sup>1</sup>, A. Pitkina<sup>1</sup>, H. Marešová<sup>1</sup>, P. Kyslík<sup>1</sup>

<sup>1</sup>Laboratory of Enzyme Technology,

*Institute of Microbiology v.v.i. Academy of Sciences of the Czech Republic, Prague, Czech Republic*

### **Background**

Factory sites, wastewater treatment plants or hospitals are representative environments containing high concentrations of xenobiotics.  $\beta$ -lactam antibiotics (BLA) in these environments could directly exert a selective pressure on bacteria, resulting in spontaneous mutations or horizontal transfer of genetic elements among them. These genetic changes could pose a threat to human health, if these bacteria become multiresistant pathogens and migrate to the clinical settings. Our knowledge about the taxonomic composition of bacterial consortia from BLA contaminated environments is scarce.

### **Objectives**

To investigate and characterize bacterial community subjected to long-term selection pressure of BLA, soil samples from the factory site of a pharmaceutical company, which has been producing  $\beta$ -lactam antibiotics for more than 50 years, were taken, analyzed, and taxonomic compositions were compared to those obtained from non-polluted soils of the same area.

### **Methods**

In this study we assessed the microbial diversity on three different sites among the factory campus and two control sites (approx. 5km from the factory) using tag-encoded 454pyrosequencing of the 16s rRNA genes.

### **Conclusions**

The selection pressure of BLA did not reduce the diversities of bacterial consortia compared to those in the reference samples, although composition of the dominant species was different. The data from culture dependent study showed that the overall resistome of the polluted soil communities was boosted not only in terms of

resistance to BLAs but also within the tetracycline, macrolide, chloramphenicol, or aminocyclitol class of antibiotics.

The data demonstrate a very strong selective pressure imposed by anthropogenic activities on the transfer of resistance determinants among bacteria.

**Background**

Laccases are multicopper oxidases widely distributed in nature and catalyze the transformation of aromatic and non-aromatic compounds with reduction of molecular oxygen to water. We cloned the syntetic optimized genes, *GILCC1* and *POXA 1B* from *Ganoderma lucidum* and *Pleurotus ostreatus* respectively in *Pichia pastoris*. In expression experiments we obtained enzymatic activities of  $451.08 \pm 6.46 \text{ UL}^{-1}$  and  $0.13 \pm 0.028 \text{ UL}^{-1}$  for *GILCC1* and *POXA 1B* respectively. We are planing to employ recombinant laccases for the degradation process of kraft pulping or dye removal from effluents.

**Objectives**

Objective was to improved the enzymatic activity of each cloned genes by improving the culture media composition.

**Methods**

We use a Plackett-Burman statistical design to evaluate media volume, inocula percentage, copper, glucose,  $\text{NH}_4\text{SO}_4$ , peptone and yeast extract concentration, each one of them with two levels, to detect the positive or negative influence and contribution percentage of each one.

## Conclusions

In both cases we improved the enzymatic activity by optimizing culture media composition. In the case of *GLCC1*; treatments 1 and 9 surpassed  $1.5 \text{ UL}^{-1}$ ; which exceeds the maximum activity obtained in previous trials  $0.13 \text{ UL}^{-1}$ ; being treatment 1 which achieved higher laccase activity  $4.69 \text{ UL}^{-1}$  meaning an increase of 36.07 times. In the case of *POXA 1B*; treatments 4 and 11 surpassed  $1200 \text{ UL}^{-1}$ ; exceeding the maximum activity obtained in previous trials  $451.08 \text{ UL}^{-1}$ ; being treatment 11 which achieved higher laccase activity  $1373.72 \text{ UL}^{-1}$  meaning a 3-fold increase enzyme activity. For both laccases genes the culture time of *P. Pastoris* was 168 hours.

**Background**

We cloned the syntetic optimized gene, *POXA 1B* from *Pleurotus ostreatus* in *Pichia pastoris*. In expression experiments we obtained an enzymatic activities of  $451.08 \pm 6.46 \text{ UL}^{-1}$ . We are planing to employ a packed bed column, with the recombinant immobilized cells for dye removal from effluents.

**Objectives**

Objective was to improved the enzymatic activity of recombinant *POXA 1B* by improving the culture media composition in a bath culture of immobilized cells of the recombinant strain.

**Methods**

We use a Plackett-Burman statistical design to evaluate media volume, copper,

glucose,  $\text{NH}_4\text{SO}_4$ , peptone and yeast extract concentration, each one of them with two levels, to detect the positive or negative influence and contribution percentage of each one. After that, a Box-Behnken design allow us to optimize the more influent factor by analyzing the three levels of factor interaction through a response surface.

### **Conclusions**

We improved the enzymatic activity from 14.4U/L at 156h (first immobilized cell assay) to 1300U/L at 168 h of immobilized cells bath culture (after statistical optimization), meaning a 90.3-fold increase enzyme activity at 168 hours. The recombinant activity of the recombinant enzyme *POXA 1B* produced by using immobilized cells; exceed the maximum activity obtained in previous free cells trials 451.08  $\text{UL}^{-1}$ ; meaning a 2.88-fold increase enzyme activity at 168 hours.

**MICROBIOLOGICAL STUDY OF SEWAGE SLUDGE COMPOSTING USING MICRO-POROUS LAMINATE MEMBRANE COVER SYSTEM TECHNOLOGY**

*T. Robledo-Mahón<sup>1</sup>, A. Rodríguez-Calvo<sup>1</sup>, G.A. Silva-Castro<sup>1</sup>, B. Montoro<sup>1</sup>, B. Rodelas<sup>1</sup>, J. González-López<sup>1</sup>, C. Calvo<sup>1</sup>*

*<sup>1</sup>Microbiology, Universidad de Granada, Granada, Spain*

**Background**

Treatment of wastewater involves generation of large amounts of solid wastes worldwide, known as sewage sludge. Composting of sewage sludge from wastewater treatment plants (WWTPs) is considered a successful strategy for its sustainable recycling.

**Objectives**

The aim of this study was to investigate the bacterial community structure and population dynamics during composting, using both cultivation-dependent and cultivation-independent techniques, to gain knowledge contributing to the improvement of the efficiency of the process.

**Methods**

The composting process was conducted during 180 days in an industrial composting plant. Samples were retrieved from a full-scale pile with semi-permeable Gore-tex covers, in combination with an air insufflation system. Waste sludge from an urban WWTP was mixed with vegetal pruning wastes as bulking agent. Microbial characterization included: enumeration of viable (platable) cells, measurements of enzyme activities, phylogenetic identification of isolates by 16S-RNA gene sequencing, and characterization of bacterial communities by a next-generation, Illumina-based sequencing approach.

**Conclusions**

Composting of sewage sludge under microporous-laminate membrane covers enhanced the degradation process, compared to other composting technologies. Changes in enumeration of cultivable microbiota took place during the 15 first days of composting. High activities of enzymes dehydrogenase, protease and arylsulphatase were observed during the first five days, suggesting a high rate of substrate degradation. Pyrosequencing data demonstrated that bacterial diversity was strongly influenced by the stage of the process. The greatest bacterial diversity was observed between days 15 and 30. These results suggest that composting under microporous-membrane covers can improve the process performance and reduce the operating cost.

**Environmental microbiology - 2**

## **COMMUNITY COMPOSITION AND DIVERSITY OF N FIXING CYANOBACTERIA ASSOCIATED WITH MOSSES IN SUB-ARCTIC ECOSYSTEMS**

A.J. Russi<sup>1</sup>, I.S. Jónsdóttir<sup>1</sup>, O.S. Andrésson<sup>1</sup>

<sup>1</sup>School of Engineering and Natural Sciences,  
Faculty of Life and Environmental Sciences, Reykjavík, Iceland

### **Background**

Moss associated cyanobacterial communities (MAC) are thought to be the major drivers of the Nitrogen (N) budget at high latitudes. Most studies have been carried out in the boreal forest and the High Arctic, whereas biological N fixation in other moss-rich regions e.g. sub-arctic alpine ecosystems may also be largely MAC-based.

### **Objectives**

To evaluate diversity, abundance and N fixation activity of cyanobacteria associated with the four moss species *Racomitrium lanuginosum*, *Hylocomium splendens*, *Pleurozium schreberi* and *Sanionia uncinata*, all abundant in Icelandic ecosystems.

### **Methods**

Moss samples were collected from three moss-dominated ecosystems in Iceland. Cyanobacterial identification and quantification was carried out by phase-contrast, fluorescence and confocal scanning microscopy. Estimation of cyanobacteria relative abundance was performed by amplification and sequencing of *nifH* genes. N fixation was assessed with the acetylene reduction assay (ARA).

### **Conclusions**

The cyanobacterial strains identified appeared to be from the orders *Stigonematales* and *Nostocales*. N fixation varied over time, also it was responsive to microclimatic/micro-topographic gradients. Simulated climate warming and grazing negatively affected N fixation activity. Moss water content and type of vegetation were the most influent parameters on potential N<sub>2</sub> fixation activity. Our finding about MAC in moss-widespread sub-arctic ecosystems may have substantial impact on the understanding of the N cycle in this terrestrial environment.

## CHARACTERIZATION OF BACTERIAL COMMUNITY ASSOCIATED WITH THE DEGRADATION OF PIG CARCASSES

H. Ryu<sup>1</sup>, Y. Kim<sup>1</sup>, B. K<sup>2</sup>, K. Cho<sup>2</sup>

<sup>1</sup>Chemical Engineering, Soongsil University, Seoul, Korea

<sup>2</sup>Environmental Engineering, Ewha Womans University, Seoul, Korea

### Background

Foot-and-mouth disease virus causes a highly contagious vesicular disease of domesticated and wild ruminants and pigs. A significant volume of infected livestock carcasses should be disposed of safely, economically and environmental-friendly.

### Objectives

Composting is one of strategies for the safe disposal of infected livestock carcasses. In this study, the bacterial community associated with the degradation of pig carcasses was characterized in the composting process of them.

### Methods

The compost bin was constructed with concrete frames for the walls and floor. Two-layer stainless steel grids were installed to put the carcasses of 4 pigs (80~90 kg/individual) in the bin. The bin was filled with well-mature compost mixture. To collect compost sample, perforated stainless steel tubes, which have been specially designed to collect sample without disturbance, were installed in the bin. Bacterial community was analyzed using 16S rDNA-PCR and pyrosequencing.

### Conclusions

The results of volatile organic compounds (VOCs) monitoring indicated that the easier degradable fractions of pig carcasses decomposed during initial 50 days, and most of pig carcasses decayed during 170 days. The VOC concentrations at the top layer of compost bin were lower than VOCs at the bottom, indicating the top layer of compost can play a role as biofilter for the removal of malodor gases. Dominant bacteria at the initial stage were *Alcanivorax*, *Aquimarina*, *Atopostipes*, *Bacillus*, *Cerasibacillus*, *Pseudomonas*, *Psychrobacter*, *Terribacillus* and *Ulvibacter*. At the active degrading period of pig carcasses, *Alcanivorax*, *Bacillus*, *Clostridium*, *Ignatzschineria*, *Lentibacillus*, *Pelotomaculum*, *Sporanaerobacter* and *Tissierella* were dominated. *Caldicoprobacter*, *Clostridium*, *Sedimentibacter*, *Syntrophaceticus* and *Virgibacillus* were followed during final composting period.

## **POTENTIAL USE OF YEASTS ISOLATED FROM FORESTED WETLAND IN AZO DYES DECOLORIZATION**

A. Sampaio<sup>1</sup>, P.A. Pinto<sup>2</sup>, R.M.F. Bezerra<sup>2</sup>, A.A. Dias<sup>2</sup>

<sup>1</sup>*Biology and Environment, University of Trás-os-Montes e Alto Douro, Vila Real, Portugal*

<sup>2</sup>*CITAB, University of Trás-os-Montes e Alto Douro, Vila Real, Portugal*

### **Background**

Forested wetlands are interfaces between terrestrial and freshwater systems and play an important role in the hydrology and nutrient filtration, acting as carbon sinks and in biodiversity regulation and maintenance. Also, despite microbial biodiversity in these systems is high, the biotechnological potential of this microbial diversity has been almost ignored, particularly yeast communities.

### **Objectives**

The main purpose of this study is to evaluate the potential exhibited by yeast isolates in decolorizing different azo dyes, for future use in bioremediation.

### **Methods**

In this work, wetlands have been screened for wild yeast isolates exhibiting ability to degrade five different azo dyes, a major group of synthetic dyes highly recalcitrant to current degradation processes. From the universe of isolates selected based on different colonial morphologies, 92 yeast isolates were randomly chosen for assessing their decolorizing abilities. Hierarchical clustering, based on medium color changes during incubations, were used to evaluate differences in the performance of azo dyes decolorization.

### **Conclusions**

Yeast isolates differed markedly in their ability to decolorize the tested dyes. Among the best eleven isolates selected and identified to the species level by molecular methods, the basidiomycetous yeasts *Cryptococcus laurentii* AGG729 and *Cryptococcus podzolicus* AGG691, showed the highest dyes removal capacity. Our

results pointed out that yeasts occurring in forested wetlands, have potential to be used in biotechnological processes, being azo dyes bioremediation a case in point.

## CHARACTERIZATION OF MICROBIAL COMMUNITIES WITHIN PETROLEUM REFINERY WASTES AND THEIR CATABOLIC POTENTIAL IN BIOREMEDIATION

P. Sarkar<sup>1</sup>, A. Roy<sup>2</sup>, S. Pał, S.K. Kazy<sup>2</sup>, P. Sar<sup>1</sup>

<sup>1</sup>Department of Biotechnology, Indian Institute of Technology Kharagpur, Kharagpur, India

<sup>2</sup>Department of Biotechnology, National Institute of Technology, Durgapur, India

### Background

Autochthonous microbial communities within the highly hazardous petroleum contaminated sites could play significant role in *in situ* bioremediation. Unlike oil spill and other hydrocarbon contaminated environments, microbial diversity and their remedial potential is least studied within petroleum refinery wastes.

### Objectives

During the present study microbial diversity and their catabolic potential relevant for *in situ* bioremediation of petroleum refinery waste were studied.

### Methods

Gas chromatography mass spectrometry, ICP, and other standard methods were used to characterize the waste sludge. Orion multiparameter meter was used to determine DO, pH, ORP, temperature on site. 16S rRNA gene sequences were obtained from metagenomes through Illumina (GAIIx) sequencer. Clone library based analysis was done to reconfirm the archaeobacterial populations. 65 bacterial strains were isolated through plating on R2A medium. BIOLOG eco plates were used to ascertain community level physiological profiles.

### Conclusions

Dominance of anaerobic, moderately thermophilic, fermentative, sulphate-, iron-, nitrate- reducing, bacterial genera like *Fervidobacterium*, *Coprothermobacter*, *Thermodesulfovibrio*, *Deferribacter*, *Nitrospira*, *Anaerolinea*, *Thermoanaerobacterium*, etc. was observed. Presence of methanotrophic and methanogenic, acetoclastic, hydrogenotrophic, archaea (*Methanoseata*, *Methanolinea*, *Methanocella*, etc.) was confirmed by both NGS and clone library analysis. Bacterial strains isolated from the samples showed their affiliation to genera *Pseudomonas*, *Bacillus*, *Burkholderia*, *Enterobacter*, *Kocuria*, *Microvirgula*, *Pandoreae* etc. The isolates were screened for their ability to grow in presence of various hydrocarbons (Naphthalene, Dodecane, etc.) crude oil, oily sludge, biosurfactant production, varied temperature (15°C - 45°C), pH (3.0 - 9.0) and heavy metals. The overall study illustrated microbial community structure and their potential in survival and hydrocarbon biotransformation, which may be exploited for *in situ* bioremediation strategies.

**CHARACTERIZATION OF THE FUNGAL ICE NUCLEATION MACHINERY BY MEANS OF  
FUSARIUM ACUMINATUM**

J. Scheel<sup>1</sup>, A. Kunert<sup>1</sup>, C. Kampf<sup>1</sup>, U. Pöschl<sup>1</sup>, J. Fröhlich-Nowoisky<sup>1</sup>

<sup>1</sup>Multiphase Chemistry, Max Planck Institute for Chemistry, Mainz, Germany

**Background**

Freezing of water above -36°C is based on ice nucleation activity (INA) mediated by ice nucleators (IN), and biological particles are a potentially important source of IN in the atmosphere. INA of the fungal genus *Fusarium* was already described about 30 years ago and INA of *Fusarium* as well as INA of other fungal genera is assumed to be mediated by proteins or at least to contain a proteinaceous compound. However, to date the precise INA machinery of *Fusarium* remains unidentified.

**Objectives**

In this study we use analytical techniques to identify INA protein in surface protein extract from *Fusarium acuminatum*. The ultimate Goal is to elucidate the biological and environmental impact of fungal IN.

**Methods**

We use liquid chromatography, customized freezing assay, SDS-page, mass spectrometry and molecular methods to subsequently analyze the fungal IN machinery.

**Conclusions**

Preliminary results show that the INA protein of *F. acuminatum* is contained in the early size exclusion chromatography fractions indicating a high molecular size. Moreover we could identify a single protein band from IN active fractions at 130-145 kDa corresponding to sizes of IN proteins from bacterial species. To our knowledge this is for the first time an isolation of a single protein from *in vivo* samples, which can be assigned as IN active from *Fusarium*.

**Environmental microbiology - 2**

## **POPULATION ANALYSIS OF BACTERIA IN A LOW TEMPERATURE WATER CATCHMENT SYSTEM**

J. Schroeder<sup>1</sup>, B. Braun<sup>1</sup>, U. Szewzyk<sup>1</sup>

<sup>1</sup>*Environmental Technology, TU Berlin, Berlin, Germany*

### **Background**

Drinking water supplies are based on groundwater resources all over the world. At some locations problems with higher concentrations of iron and manganese in groundwater can occur. The principle of subsurface iron and manganese removal are periodically injections of aerated water into an anoxic aquifer through a well, resulting in the precipitation of iron and manganese hydroxides. However, the precipitation of insoluble oxyhydroxides caused by chemical and microbial processes may result in the clogging of the aquifer and pumps.

### **Objectives**

Bacterial communities of water wells from a water catchment system with subsurface iron and manganese removal were determined to identify key bacteria. Phylogenetic diversity and relative abundance of bacteria in water samples were compared between wells already in operation to those not yet operated.

### **Methods**

To estimate well-clogging, qPCR with universal primers was performed for all samples and specific primers targeting (i) *Rhodoferax* spp., (ii) *Crenothrix polyspora* and (iii) *Gallionella* spp. were applied. Furthermore, PCR-DGGE technique and 454-pyrosequencing were used to observe bacterial alterations within water samples.

### **Conclusions**

Our results showed that wells in operation contained a higher alpha-diversity, and bacterial communities were dominated by *Rhodoferax* and *Methylobacter*. Abundant groups in not yet operated wells were *Gallionella* spp. and *Crenothrix polyspora*. Redundancy analyses were performed to determine a relationship between samples and environmental factors. The parameters nitrate, iron(III) oxide, iron(II) oxide and ammonia create differences between bacterial communities in operated and not yet operated wells.

The diversity and composition of native microbial populations in water samples differed fundamentally from those influenced by operation.

## **MARINE HYDROCARBONOCLASTICUS BACTERIA AS WHOLE-CELL BIOSENSORS FOR N-ALKANES**

E. Sevilla<sup>1</sup>, L. Yuste<sup>1</sup>, F. Rojo<sup>1</sup>

<sup>1</sup>*Microbial Biotechnology, Centro Nacional de Biotecnología, Madrid, Spain*

### **Background**

Whole-cell biosensors are useful systems for the *in-situ* monitoring of seawater for hydrocarbons derived from oil spills. Currently available biosensors for hydrocarbons show limitations derived from the low solubility in water of hydrocarbons or the high ionic strength of seawater.

### **Objectives**

We compared the performance of a biosensor system for the detection of short chain alkanes in seawater, hosted in either *E. coli* (commonly used in many whole-cell biosensors but not optimized for alkane degradation) or different marine hydrocarbonoclastic bacteria specialized in assimilating alkanes.

### **Methods**

A set of reporter strains containing a plasmid harbouring the reporter circuit was constructed. Fluorescence assays were carried out to study the time-dependent response of the reporter strains to different alkanes at different concentrations, and the response of reporter strains to real samples such as seawater contaminated with petrol or crude oil.

### **Conclusions**

Some of the marine hydrocarbonoclastic bacteria tested performed better than *E. coli*. These strains showed very good response to seawater containing pure alkanes, petrol and crude oil in just 2 hours. *Alcanivorax borkumensis* proved to be the best host for the biosensor system.

<sup>2</sup>Biological Sciences, University of Calgary, Calgary, Canada

### **Background**

In an oil polluted site, several components of environmental concern can be found including Polycyclic Aromatic Hydrocarbons (PAH), Dibenzothiophene (DBT) and metals. Studies showed that the naturally occurring soil bacteria are able to transform them to safe end products (bioremediation).

### **Objectives**

1- To find tolerance of *Burkholderia fungorum* DBT1 (B.DBT1) and *Burkholderia fungorum* 95 (B.95) to DBT and PAH mixture and in planktonic and biofilm forms 2- Evaluating the growth and transformation ability of these strains in presence of selenium and tellurium as sample inorganic pollutants.

### **Methods**

The growth as biofilm in 96 well plate was established for both strains using Calgary Biofilm Device (CBD) with the method described by Ceri et al., 1999. Growth curves were drawn based on CFU counting on YMA plates. Biofilm photos were taken by Confocal Microscopy. Selenite and tellurite reduction efficacy assessment was performed based on protocols described by Kessi et al, 1999 and Turner et al, 1992 respectively.

### **Conclusions**

Both strains can tolerate high concentrations of DBT (2048 ppm) in both planktonic and biofilm forms while the mixture of PAH can only be tolerated by planktonic form for both strains. B.95 is able to tolerate the maximum used concentration of selenite (2 mM) and transform more than half amount to elemental selenium. On the other hand B.DBT1 can only convert 0.5 mM of selenite, while is able to transform completely initial 0.1 mM concentration of tellurite to elemental tellurium.

**VINASSE AS SUBSTRATE FOR GROWTH MICROBIAL CONSORTIUM-  
ALTERNATIVE FOR TREATMENT AND RE-USE WASTE.**

C. Silva<sup>1</sup>, J.F. Pires<sup>1</sup>, K.C. Reis<sup>1</sup>, G.M.R. Ferreira<sup>1</sup>, R.F. Schwan<sup>1</sup>

<sup>1</sup>Biology, Federal University of Lavras, Lavras, Brazil

**Background**

Vinasse showed to be appropriate substrate for yeast growth in single culture. The use of vinasse as a substrate for microbial biomass production can be an alternative for the treatment and reuse of this waste.

**Objectives**

The objectives of this study were (i) to evaluate the biomass production by *Bacillus subtilis* and two strains of *Saccharomyces cerevisiae* in mixed culture using the vinasse as a substrate, (ii) investigate the nutritional quality of the product generated, (iii) to evaluate the effect of biological treatment on physico-chemical parameters and level of toxicity.

**Methods**

*B. subtilis* (CCMA 0087), *S. cerevisiae* (CCMA0137) and *S. cerevisiae* (PE2) were initially grown in 100 ml vinasse medium (49% v/v vinasse, 49% distilled water, 1% glucose and 1% yeast extract). The microorganisms grown in a consortium, two by two, and each consortium was conducted in three different cell concentration. During the incubation period were monitored the cell number and pH. After that, the dry biomass and the reduction in Chemical oxygen demand (COD) and biochemical oxygen demand (BOD) of treated vinasse was evaluated.

**Conclusions**

Based on these results, the best combination and concentration of microorganisms was selected for cultivation in bioreactor. During the incubation period the bioreactor same previous parameters were monitored. In addition to the COD and BOD, the treated vinasse was evaluated for acute phytotoxicity. The data obtained showed that the two strains of *S. cerevisiae* in mixed culture with an initial population of  $10^7$  cells/mL showed 176mg/L of biomass and reducing the power polluter of vinasse.

## DISTRIBUTION AND GENOMIC ADAPTATION OF METHANOMASSILIICOCCALES ECOTYPES IN WETLANDS AND ANIMAL INTESTINAL TRACTS

A. Söllinger<sup>1</sup>, C. Schwab<sup>2</sup>, T. Weinmaier<sup>3</sup>, A. Loy<sup>3</sup>, A.T. Tveit<sup>4</sup>, C. Schleper<sup>1</sup>, T. Urich<sup>1</sup>

<sup>2</sup>Laboratory of Food Biotechnology, Institute of Food Nutrition and Health, Zürich, Switzerland

<sup>3</sup>Department of Microbiology and Ecosystem Science, Faculty of Life Sciences, Vienna, Austria

<sup>4</sup>Department of Arctic and Marine Biology, Faculty of Biosciences Fisheries and Economics, Tromsø, Norway

### Background

Methane (CH<sub>4</sub>) is a very potent greenhouse gas, mainly produced by methanogenic archaea as an endproduct of their anaerobic respiration. Methanogenic archaea are phylogenetically diverse and living in a broad range of anaerobic environments, among others, in wetlands and ruminant animals, which represent the major natural and anthropogenic CH<sub>4</sub> sources. Recently, a novel order of methanogens, the *Methanomassiliicoccales*, was discovered.

### Objectives

We aimed to assess the environmental distribution of *Methanomassiliicoccales* in different wetlands (arctic and acidic/neutral temperate peat) and animal intestinal tracts. Additionally, a metagenomic characterisation of *Methanomassiliicoccales* enrichments was intended.

### Methods

Screening for *Methanomassiliicoccales* 16S rRNA and *mcrA* genes showed that *Methanomassiliicoccales* are widely distributed in wetlands and animal intestinal tracts. Phylogenetic analyses of 16S rRNA genes revealed two distinct animal and wetland clusters, pointing to two fundamentally different ecotypes. Ruminant enrichment cultures grow in an anaerobic medium supplemented with trimethylamine and H<sub>2</sub> as substrates. *Methanomassiliicoccales* represented one major methanogenic group in the bovine rumen performing H<sub>2</sub>-dependent methylotrophic methanogenesis. Two partial *Methanomassiliicoccales* genome bins assembled from rumen metagenomes represented the two ecotypes and enabled the characterisation of the underlying genomic basis of their adaptations. Ecotype differences were reflected e.g. by the smaller genome size of the animal-associated ecotype as well as a higher abundance of genes for oxidative stress response in the soil ecotype.

### Conclusions

Our findings suggest that *Methanomassiliicoccales* represent a novel ecologically important group of methanogens with distinct animal and soil associated ecotypes adapted to these different environments. Especially the animal-associated ecotype potentially plays an important role in global CH<sub>4</sub> formation.

**OZONATION FOR THE REDUCTION OF THE MICROBIAL LOAD OF WASTEWATERS**

<sup>3</sup>CBQF – Centro de Biotecnologia e Química Fina – Laboratório Associado, Escola Superior de Biotecnologia Universidade Católica Portuguesa, Porto, Portugal

**Background**

Treated municipal wastewater contains microbial densities up to 10<sup>6</sup> CFU/100mL. Ozonation is an oxidation process widely used to disinfect water due to the strong ozone biocidal properties.

**Objectives**

This work aimed at assessing the effectiveness of ozonation on the reduction of the microbial load of treated wastewater.

**Methods**

A synthetic wastewater containing a mixture of fungi and bacteria, including antibiotic resistant and endospore forming strains, was submitted to ozonation assays performed in a 1L lab-scale reactor, with contact periods of 15, 30 and 60 min. The treatment efficiency was assessed based on the microbial enumeration and quantification of 16S rRNA, and selected indicator genes, before and after ozonation and after three days of storage at room temperature.

**Conclusions**

Ozonation for 15 min reduced the total heterotrophic bacteria and fungi by 3 log and 1 log, respectively. Coliforms and enterococci were extensively removed, being detected at densities of about 5 CFU/100mL. However, 3 days after water ozonation, a strong recovery was observed, with total heterotrophs reaching 10<sup>9</sup> CFU/100mL and fungi 10<sup>2</sup> CFU/100mL. Total coliforms and enterococci were still detected after 3 days. After 30 and 60 min of ozonation, viable cell counts were below the detection limit (1 CFU/100mL) and no recovery was observed after 3 days. Using culture independent methods, it was possible to confirm those results, being observed significant reductions of selected indicator genes after 15-30 min treatments. However, both 16S rRNA and *bla*<sub>TEM</sub> genes, but not *vanA*, were detected after 3 days recovery.

## MIGRATORY HABITS, AREA AND HABITAT INFLUENCE THE MICROBIOTA OF BIRDS IN THE DANUBE DELTA NATURAL RESERVE

M. Spinu<sup>1</sup>, E. Pall<sup>1</sup>, C.D. Sandru<sup>1</sup>, G.F. Brudasca<sup>1</sup>, A.I. Pastiu<sup>1</sup>, M. Niculae<sup>1</sup>

<sup>1</sup>Infectious Diseases, University of Agricultural Sciences and Veterinary Medicine, CLUJ-NAPOCA, Romania

### Background

Wild birds from aquatic habitats could, as reservoirs and vectors for antibiotic resistant bacterial pathogens, directly affect the health of animals and pose serious risks to residents and tourists, the microbial load and its variety increasing with the broadening of the habitat and depending on the migration area.

### Objectives

The research aimed to monitor the variation and distribution of pathogenic bacteria in birds with different migratory habits, areas and habitats in the Danube Delta.

### Methods

A total of 112 rectal and oro-pharyngeal swabs from 26 species of migratory and sedentary birds from the Danube Delta Natural Reserve were collected and subjected to classical cultivation or enrichment techniques. 113 strains were identified on Chromogenic UTI medium Brilliance™ and TCBS Cholera medium (Oxoid) as belonging to *Vibrio*, *Pseudomonas*, *Proteus*, *Escherichia*, *Staphylococcus* and *Enterococcus* genera. Pathogenic bacteria were prevalent in migratory versus sedentary birds, with alarming proportions of *Vibrio spp.* (23.89%), followed by *E.coli*/coliforms (21.26%) (table 1):

Bacterial pathogens (%) isolated from cloacal and oro-pharyngeal specimens collected from wild bird species in the Danube Delta Natural Reserve (Table 1).

	V. cholerae, V. fluvialis	V. alginolyticus, V. metschnikovii	Pseudomonas spp.	V. mimicus, V. vulnificus	Proteus spp	Coliforms	Staphylococcus spp.	Enterococcus faecalis	E. coli
Wild birds									
Sedentary	11.1	37.5	37.5	30	28.57	35.7	28.57	44	30
Migratory	88.9	62.5	62.5	70	71.43	64.3	71.43	56	70

Of total strains	7.96	7.08	7.96	8.85	6.19	12.39	18.58	22.12	8.87
------------------	------	------	------	------	------	-------	-------	-------	------

## Conclusions

Thus, the bacterial load but not the spectrum of isolated species is influenced by migration site and habits rather than habitat.

## **BIODEGRADATION OF PERCHLOROETHYLENE AND TRICHLOROETHYLENE UNDER AEROBIC CONDITION**

S. Srinivasan<sup>1</sup>, S. Lee<sup>1</sup>

<sup>1</sup>*Department of Life Science, Kyonggi University, Suwon, Korea*

### **Background**

Tetrachloroethene (also known as perchloroethylene; PCE) and trichloroethylene (TCE) are highly chlorinated hydrocarbons, are the common groundwater contaminants in industrial areas. Dechlorination of hydrocarbons is a complex process and biological dehalogenation under aerobic condition also required more clarification.

### **Objectives**

The hydrocarbon degrading bacterial communities produces mono/di oxygenase enzymes and has the potential to degrade the chlorinated hydrocarbons with co-metabolic pathways. Soil samples were collected from contaminated site and enrichment of specific microbial communities were obtained using methanol and toluene as sole carbon source.

### **Methods**

The enrichment cultures Ui-mix and MEOH-1 were examined for the ability to degrade TCE and PCE under aerobic condition. Growth and degradation rate are examined using spectrophotometer and gas chromatography equipped with ECD. The colonies on the enrichment cultures are isolated, purified and identified based on the 16S rRNA gene sequencing.

### **Conclusions**

We have developed two consortiums which can degrade the PCE and TCE completely in aerobic condition. Ui-mix and monocultures from the consortium showed highest degradation effectivity to co-metabolize TCE along with toluene as sole carbon source. Similarly, the MeOH-1 and monocultures degraded PCE under aerobic condition. The consortium Ui-mix contain diverse group of bacteria includes *Chryseobacterium*, *Pseudomonas*, *Enterobacter* and *Microbacterium*; similarly *Pseudomonas*, *Hyphomicrobium*, *Cupriavidus*, and *Microbacterium* are isolated from MeOH-1. The strains M3-1, M3-3 and M3-7 showed 98.4%, 95.3% and 94.5% removal efficiency of TCE and PCE within 20 days, respectively. Further studies have to be performed to optimize and enhance the removal efficiency and it gives a gateway for the bioremediation of chlorinated ethane.

**METHANOGENIC ACTIVITY AND DISTRIBUTION OF THE  
METHANOMICROBIALES IN TRANSITIONAL BOG AND SWAMP FOREST PEAT  
PROFILES (POLESKI NATIONAL PARK, POLAND)**

A. Szafranek-Nakoneczna<sup>1</sup>, A. Pytlak<sup>1</sup>, Z. Stępniewska<sup>1</sup>

<sup>1</sup>Biochemistry and Environmental Chemistry,  
The John Paul II Catholic University of Lublin, Lublin, Poland

**Background**

Peatlands are the largest natural carbon storage. Under good aeration conditions carbon is released as a CO<sub>2</sub> but when there is lack of oxygen, anaerobic brake down of organic matter take place and CH<sub>4</sub> release occur. In most peatlands with neutral pH, the main substrate of CH<sub>4</sub> production is acetate while in acidic, the main precursors are CO<sub>2</sub> and H<sub>2</sub>. CH<sub>4</sub> production is attributed to the activity of methanogenic *Archaea*, which, in peat soils are represented in majority by the members of the *Methanomicrobiales*.

**Objectives**

The aim of presented work were: (1) to examine which layers of the peat soil profiles (from the surface top to a mineral base) in transitional peat bog and swamp forest surrounding eutrophic Lake Moszne in Poleski National Park (East of Poland) show the highest methanogenic activity; (2) to test the presence of the *Methanomicrobiales* in investigated peat materials.

**Methods**

Methanogens were detected in fresh samples *via* FISH technique using MG1200 probe. Soil samples were further incubated anaerobically (at 5-30°C) and CH<sub>4</sub> production (gas chromatography technique) was controlled.

**Conclusions**

The highest methanogenic activity (up to 39.46 mg CH<sub>4</sub> kg dw<sup>-1</sup> d<sup>-1</sup>) below layers 45 cm (transitional bog) and 150 cm (swamp forest) were found. In all of the investigated samples the presence of coccus, bacillus and curved rods from the *Methanomicrobiales* were confirmed. Among investigated, morphologically diverse order, the dominant role plays coccus (up to 100%) while the rarest were representatives of curved rods (up to 9%).

## **RESPONSE OF THE COALBED ROCK METHANOTROPHIC COMMUNITY TO TEMPERATURE CHANGES**

A. Szafranek-Nakonieczna<sup>1</sup>, A. Pytlak<sup>1</sup>, Z. Stępniewska<sup>1</sup>, A. Kuźniar<sup>1</sup>, A. Wolińska<sup>1</sup>

<sup>1</sup>Biochemistry and Environmental Chemistry,

*The John Paul II Catholic University of Lublin, Lublin, Poland*

### **Background**

Methanotrophic bacteria are ubiquitous in the environment and play an important role in the global carbon cycling. Recently published research revealed that in spite of severe oxygen limitation, aerobic methanotrophic species are also found in deep subsurface geological formations such as coalbed rocks. These rocks are excavated in huge amounts during coal exploitation and comprise a troublesome waste. The presence of the methanotrophic community creates an opportunity to reuse these materials for the purpose of methane biofiltration; however surface conditions vary much from these *in situ*, especially according to temperature, which in geological formations is stable (c.a. 30 °C).

### **Objectives**

In the current study we investigated methanotrophic communities of the rocks originating from Upper Silesian (Poland) coal mines in terms of identity (16S rRNA sequences) and response to the temperature changes.

### **Methods**

Assays were performed in hermetic microcosms where samples of 15 g of rock were incubated under mixtures of methane and air. Headspace gases were measured by means of gas chromatography. DNA was isolated using PowerSoil® DNA Isolation Kit (MoBio) and amplicons obtained with methanotroph-specific IF/IR, IIF/IIR primers.

### **Conclusions**

The investigated microbial communities were heterogeneous and consisted of both type I and II methanotrophs. Their ability of to oxidize methane decreased along with temperature and in majority, yet not all, of the samples was inhibited at 10 °C. It was hypothesized that the potential of methane turnover in the coal bed rocks is related with identity of the methanotrophic inhabitants with type II methanotrophs ( $\alpha$ -Proteobacteria) being responsible for methane oxidation at low temperatures.

**UTILIZATION OF RHAMNOLIPIDS DURING BIOSURFACTANT-MEDIATED  
BIOREMEDIATION OF HYDROCARBON-POLLUTED SOIL**

A. Szulc<sup>1</sup>, M. Sydow<sup>1</sup>, M. Woźniak<sup>1</sup>, P. Lisiecki<sup>1</sup>, L. Ławniczak<sup>1</sup>, L. Chrzanowski<sup>1</sup>

<sup>1</sup>*Institute of Chemical Technology and Engineering, Poznan University of Technology,  
Poznan, Poland*

**Background**

It was proven that rhamnolipids are environmental-friendly biosurfactants produced by *Pseudomonas* species. There are many studies dealing with rhamnolipids-mediated bioremediation of hydrocarbons. However, it must be mentioned that both the environmental fate and the influence of rhamnolipids on microbial communities remain unexplained. We hypothesize that rhamnolipids could be more readily utilized by soil microbial communities than hydrocarbons.

**Objectives**

1. to investigate and compare biodegradation rates of rhamnolipids and hydrocarbons.
2. to investigate the effect of rhamnolipids on quantitative and qualitative composition of microbial community

**Methods**

Biodegradation rates – HPLC-MS, structure of the microbial community – Illumina.

**Conclusions**

In most cases at least 80% of monorhamnolipids and dirhamnolipids were degraded during field experiment. The biodegradation rates of hydrocarbons was significantly lower compared with rhamnolipids. Rhamnolipids are more preferentially degraded by soil microorganisms than hydrocarbon compounds. Thus, we suggest that the role of rhamnolipids during bioremediation processes may be negligible.

## **CHARACTERIZATION OF A PSEUDOMONAS SP. ISOLATED FROM BRAZILIAN SOIL AND ITS ABILITY TO DEGRADE ATRAZINE.**

A. Tonelli Fernandes<sup>1</sup>, V. Vicente Martins<sup>1</sup>, E. Guedes Stehling<sup>1</sup>

<sup>1</sup>*Clinical toxicological and chemical analysis,*

*Pharmaceutical Sciences Faculty of Ribeirão Preto, Ribeirão Preto, Brazil*

### **Background**

Atrazine is a selective and systemic herbicide used for controlling weeds in several crops. It is considered an environmental pollutant due to its high potential to contaminate the surface water and groundwater. *Pseudomonas* sp. ADP, the model strain for atrazine biodegradation, mineralizes this herbicide using it as a nitrogen source.

### **Objectives**

Characterization of a strain isolated from a Brazilian soil sample and its ability to degrade atrazine.

### **Methods**

The soil sample was collected in Ribeirão Preto, São Paulo, and processed according to the method describe by Gargouri et al. (2013), with modifications. The strain was selected from ATZ-R medium, in accordance with the formation of clear zones around the colonies. The identification was performed by 16S rRNA sequence analysis. PCR reactions for detection of *atz* genes (*atzA*, *atzB*, *atzC*, *atzD*, *atzE* and *atzF*) was carried out according to the methodology of Devers et al. (2004) and, then, sequenced. Plasmidial DNA extraction was performed according to the alkaline lysis technique, previously described by Birboin & Doly (1979). The degradation test was performed in solid and liquid ATZ-R medium.

### **Conclusions**

The strain was identified as *Pseudomonas* sp., presented all *atz* genes and a 35 MDa plasmid, however, only the *atzA* gene was detected in this plasmidial DNA. The strain was capable to mineralize this herbicide after 48 hours in solid medium, indicated by the clear zones around the colonies. The analysis of the ATZ-R liquid medium in spectrophotometer (225 nm) showed a significant decrease of atrazine after 48 hours of incubation.

**THE MICROORGANISM THAT NEVER READ THE LITERATURE - FASTEST GROWING PHOTODAMAGE TOLERANT ALGA ISOLATED FROM DESERT CRUSTS, DEPENDS ON PIONEER FILAMENTOUS CYANOBACTERIA SPECIES TO SURVIVE DESICCATION**

H. Treves<sup>1</sup>, H. Raanan<sup>1</sup>, N. Keren<sup>1</sup>, Y. Shotland<sup>2</sup>, I. Ohad<sup>1</sup>, A. Kaplan<sup>1</sup>

<sup>1</sup>Plant and Environmental Sciences, Hebrew University, Jerusalem, Israel

<sup>2</sup>Chemical Engineering, Shamoon College of Engineering, Beer-Sheva, Israel

**Background**

With the premise that unique capabilities can be found in microorganisms facing extremely harsh conditions, we focused our efforts on desert biological sand crusts (BSC), one of the harshest environments to support life. Recently, we have isolated a small green alga (named *Chlorella ohadii*), which does not conform to some of the basic fundamentals in microbial ecology and photosynthesis:

**Objectives**

1. Acquired ability to acclimate to extreme environments is usually accompanied by reduced performance under optimal conditions. We intend to show that *C. ohadii* **does not obey this rule**. In its natural habitat, *C. ohadii* is facing diurnal desiccation-hydration cycles, vast temperature amplitudes and extremely high illumination intensities, yet when grown under optimal laboratory conditions it exhibits the fastest growth rates ever reported for an alga.

2. After many years of research, some feel that we have elucidated the functioning of the photosynthetic machinery, and what sets the upper limit for algal growth. However, the unparalleled fast growth, extremely high photosynthetic rates and resistance to photodamage, suggest this **may not be the case**. Namely, *C. ohadii* has been shown to be completely resistant to photoinhibition, and its productivity was unaffected by irradiances as high as twice full sun light.

3. Survival of *C. ohadii* in its BSC habitat depends on close association with filamentous cyanobacteria; **a unique and novel mode of interspecies interaction**.

**Methods**

We wish to present detailed physiological analysis of the unique properties supporting this phenomenal growth and resistances, combined with insights from their genomic, transcriptomic and metabolomic characterization.

**Conclusions**

Treves, H., Raanan, H., Finkel, O., Berkowicz, S., Keren, N., Kaplan, A. (2013) A newly isolated *Chlorella* sp. from desert sand crusts exhibits a unique resistance to excess light intensity. FEMS Microbiology Ecology. doi:10.1111/1574-6941

## **DETERMINING THE EFFECT OF SAMPLING VOLUME AND FLOW RATES ON INVESTIGATIONS OF BACTERIAL COMMUNITY DIVERSITY IN A LOW BIOMASS AQUATIC ENVIRONMENTS**

*S. Ugarcina Perovic<sup>1</sup>, Q.M. Bautista<sup>2</sup>, M.C. Rivera<sup>2</sup>, J. Russell<sup>2</sup>, A.J. Pinto<sup>2</sup>*

<sup>1</sup>*Faculty of Sciences, University of Novi Sad, Novi Sad, Serbia*

<sup>2</sup>*School of Engineering, University of Glasgow, Glasgow, United Kingdom*

### **Background**

As water travels from treatment plant through the pipelines to consumer's taps, the diverse drinking water microbiome varies in abundance and in composition as a result of a large number of variables. A quantitative understanding of relevant variables is essential towards ensuring better control of drinking water quality. Increasingly, DNA sequencing approaches such as 454 pyrosequencing and Illumina MiSeq sequencing are being utilised to this end. Yet, little has been done to understand the influence of sample collection protocols on the data collected through DNA sequencing approaches. The ability to accurately understand the factors that affect the change in the drinking water microbiome is critically reliant on the robust approaches for sample collection.

### **Objectives**

The goal of this study was to understand the effect of sample volume and sampling flow rate on the structure and membership of drinking water bacterial communities. Understanding these effects is especially critical in drinking water systems, which represents a low biomass but high diversity aquatic environment.

### **Methods**

To do this, we sampled at five different residential sampling locations in the City of Glasgow, UK. This sampling was conducted such that five different sample volumes, ranging from 1 to 20 litres, were filtered to harvest microbial cells at each sampling location and this exercise was repeated at two different flow rates at the faucet (laminar and turbulent flow regimes).

### **Conclusions**

We will provide a detailed overview of these two variables on the reproducibility and reliability of DNA sequencing based investigations of the drinking water microbiome.

**PHYSIOLOGIC AND GENOMIC CHARACTERIZATION OF A NOVEL NITROSPIRA SPECIES ENRICHED UNDER ANAEROBIC, DENITRIFYING CONDITIONS**

M.A.H.J. van Kessel<sup>1</sup>, S. Lücker<sup>1</sup>, D.R. Speth<sup>1</sup>, M.S.M. Jetten<sup>1</sup>, H.J.M. Op den Camp<sup>1</sup>

<sup>1</sup>Microbiology, Radboud University, Nijmegen, Netherlands

**Background**

Members of the genus *Nitrospira* are dominant in many natural habitats and of vital importance for wastewater treatment. They are chemolithoautotrophic organisms capable of growth with nitrite and CO<sub>2</sub> as sole energy and carbon source. It further has been demonstrated that some *Nitrospira* can utilize simple organic carbon compounds and molecular hydrogen as alternative substrates and can switch to nitrate reduction under oxygen limitation. However, this metabolism has been assumed to be a survival strategy and in most systems studied so far *Nitrospira* was outcompeted by denitrifying organisms when anoxic conditions prevailed.

**Objectives**

Here, a community of nitrogen cycle bacteria was enriched from the anaerobic compartment of a biofilter connected to a recirculating aquaculture system.

**Methods**

The culture was fed with filtered water from the aquaculture system, supplemented with ammonium, nitrite and nitrate.

**Conclusions**

A stable enrichment culture was obtained which anaerobically converted ammonium, nitrite and nitrate into dinitrogen gas. The culture was dominated by anaerobic ammonium-oxidizing *Brocadia* species, a denitrifier (*Denitratisoma*), and a *Nitrospira* species. Anammox bacteria and *Nitrospira* co-aggregated, while the denitrifiers formed separate clusters. This culture shows that anaerobic ammonium oxidizers and nitrite oxidizers, who were considered to be mutually exclusive, can be grown as a stable co-culture. Furthermore, this shows that some *Nitrospira* species can be competitive under nitrate-reducing conditions. This study demonstrates another unexpected lifestyle for an organism believed to be only competitive under aerobic lithoautotrophic conditions. It further indicates that *Nitrospira* in combination with anammox can be of interest for anoxic wastewater treatment systems.

## **OXALATE-DEGRADING ABILITY IS UBIQUITOUS IN DIAZOTROPHIC AZOSPIRILLUM**

A. Venieraki<sup>1</sup>, M. Dimou<sup>1</sup>, E. Vezyri<sup>1</sup>, P. Katinakis<sup>1</sup>

<sup>1</sup>Dept. of Crop Science, Agricultural University of Athens, ATHENS, Greece

### **Background**

Oxalate-degrading bacteria are known from a wide variety of ecological niches and different taxonomical origins. They play important roles in local and global carbon-cycling and, when present in the guts of mammals, they seem to provide protection against excess oxalate uptake and renal stones.

### **Objectives**

In the present study, we aim to investigate the ability to grow at minimal medium with Ca-oxalate or Na-oxalate as a sole carbon source of 30 diazotrophic *Azospirillum* strains isolated from the rhizosphere of various field grown gramineous plants species grown at different geographical Greek locations, molecular characterized at our previous research works, and reference type strains. Most of these strains tested for the ability to grow at minimal medium with oxalate crystals isolated from *Amaranthus blitum* (family *Amaranthaceae*) as a sole carbon source. Additionally, we investigated for the presence of formyl-CoA transferase (*frc*) gene a molecular marker used for the specific detection and identification of oxalotrophic bacteria involved in oxalate degradation.

### **Methods**

Minimal media with Ca-oxalate/Na-oxalate or oxalate crystals from plant were used as a sole carbon source for bacterial growth. Molecular biology techniques and phylogenetic analysis for the *frc* genes.

### **Conclusions**

The majority of the examined strains display an ability to use oxalic acid as a sole carbon source. This result and the presence of the *frc* genes shows that these strains can metabolize oxalate via the oxalyl - CoA - decarboxylase pathway to produce formate and incorporate it in their metabolism.

**DETOXIFICATION AND BIODEGRADATION OF ENVIRONMENTAL  
POLLUTANTS BY MARINE MICROBIAL CONSORTIA**

G.A.L. VIEIRA<sup>1</sup>, L.A. DUARTE<sup>1</sup>, L.D. SETTE<sup>1</sup>

<sup>1</sup>*Department of Biochemistry and Microbiology, Institute of Biosciences - UNESP,  
Rio Claro, Brazil*

**Background**

The high industrial activity causes several environmental problems, mainly due to the discharge of wastes. Marine environments are susceptible to contamination by industrial waste and also may represent a target niche for microbial prospecting for bioremediation. Marine microorganisms are adapted to saline conditions and have potential for being used in many processes.

**Objectives**

To evaluate the potential of microbial consortia in detoxify and degrade environmental pollutants.

**Methods**

Microbial consortia were structured in different combinations using four ligninolytic fungi from marine environments, two bacteria from oil reservoir and two lipolytic yeasts from Antarctica, previously selected based on their capacity to produce enzymes and to degrade hydrocarbons. Erlenmeyer flasks containing 50 ml of mineral medium, the microbial consortium and the pollutant (RBBR 500 ppm and Diesel oil 1% vv) were kept in incubators for 7 (RBBR), 14 and 21 (diesel oil) days at 140 rpm and 28 °C. Samples were analyzed in Microtox for acute toxicity and ligninolytic enzymes (Lac, MnP, LiP) were quantified.

**Conclusions**

Consortium 7 showed promising results in the studies with RBBR dye, presenting discoloration up to 70% and a very low rate of mycelial adsorption (11%). Enzymatic production of Lac was up to 141 U/L. LiP and MnP production were very low. All samples containing RBBR were detoxified. Samples containing diesel oil presented no detoxification and the production of ligninolytic enzymes was higher for MnP (114 U/L). A longer period of incubation and/or a lower concentration of oil will be tested, since this compound is highly complex.

Lanzhou, China

### **Background**

**Tuberculosis (TB) is a major public health problem in China. Gansu has very high annual attendance rate of TB in China, and the province is also famous because of its severe dust storms. The epidemic timing starts in February and ends in July, and the dust storm mainly distribute throughout the spring and early summer, which strongly indicate a close linkage between causative agent of TB and dust storm events.**

### **Objectives**

We investigated the general impact of dust storms to TB across time by analyzing variation in weekly clinic visits in Gansu during 2005-2012 in relation with the climatic event.

### **Methods**

We applied Mann-Whitney-Pettitt test and regression model to detect the seasonal periodicity of TB and dust storm in a time series, and assess relationships between the meteorological variables and weekly TB clinic visits.

### **Conclusions**

By comparing the information on cases of TB of Gansu weekly reported with dust storm events, we found a clear link between population dynamics of the disease and the climate disaster: the onset of epidemics and the dust storm shared the almost same mean week. Particulate matter might be the direct reason for the outbreak of TB in dust storm days. To our knowledge, this is the first population-based study that provides a clear demonstration that epidemic of TB was affected by dust storm in China, which will help understanding the association between this environmental problem and the evolution of epidemic disease.

**GENETIC INSIGHTS INTO THE SULFUR OXIDATION PATHWAY OF SULFUR CHEMOLITHOTROPHS LIVING IN FRESHWATER LAKES**

T. Watanabe<sup>1</sup>, H. Kojima<sup>1</sup>, M. Fukui<sup>1</sup>

<sup>1</sup>*The Institute of Low Temperature Science, Hokkaido University, Sapporo, Japan*

**Background**

Chemolithotrophic sulfur-oxidizing bacteria are capable of oxidizing inorganic sulfur compounds as sources of energy for growth. A number of genomic studies have been taken place focusing on sulfur oxidizers living in habitats where a sufficient amount of reduced inorganic sulfur compounds are available. These studies revealed that taxonomically diverse sulfur chemolithotrophs use different enzymes for the oxidation of various sulfur compounds. On the other hand, sulfur chemolithotrophs living in freshwater lakes, where the availability of reduced inorganic sulfur compounds is generally low, have been overlooked. Recently, we revealed the dominance of betaproteobacteria in the sulfur-oxidizing bacterial community of freshwater lakes, and isolated several of them in pure culture.

**Objectives**

The aim of this study is to gain genetic insights into the sulfur oxidation pathway of sulfur chemolithotrophs isolated from freshwater lakes.

**Methods**

The genomes of the new isolates were sequenced and then analyzed focusing on the composition and phylogeny of genes for sulfur oxidation. In addition, their genomes were compared with available complete genomes of other sulfur oxidizers.

**Conclusions**

As the first comprehensive comparative genomic analysis focused on sulfur chemolithotrophs from freshwater lakes, the results of our study revealed that they possess common sets of genes putatively involved in sulfur oxidation. One of these gene sets was shared only by freshwater sulfur-oxidizing betaproteobacteria.

**Environmental microbiology - 2**

## **NITROTOGA - A MAIN NITRITE OXIDIZER IN LOW TEMPERATURE ENVIRONMENTS**

S. Wegen<sup>1</sup>, S. Luecker<sup>2</sup>, E. Spieck<sup>1</sup>

<sup>1</sup>Microbiology and Biotechnology, University Hamburg, Hamburg, Germany

<sup>2</sup>Microbiology, Radboud University Nijmegen, Nijmegen, Netherlands

### **Background**

*Candidatus Nitrotoga arctica* is a cold adapted nitrite-oxidizing bacterium (NOB), which was cultivated from the Siberian Arctic. Since 2007, *Nitrotoga*-like NOB could be detected in different natural and technical environments e.g. beneath the Antarctic ice sheet, in cave systems, in wastewater treatment plants and in aquaculturing facilities. Thus, they are more distributed than previously assumed and of importance for the global nitrogen cycle as well as for a successful nitrification in wastewater processing.

### **Objectives**

The aim of this project is to gain a deeper understanding of the phylogenetic diversity within the genus *Nitrotoga* belonging to the *Betaproteobacteria* and to compare representatives derived from natural and artificial ecosystems.

### **Methods**

The 16S rRNA gene was analysed combining specific and semi specific primer pairs for Eubacteria and *Nitrotoga*. Additionally, the beta subunit of the key enzyme of nitrification in *Nitrotoga* and other NOB, the nitrite oxidoreductase B (nxrB), was sequenced.

### **Conclusions**

So far, *Nitrotoga*-like bacteria from widespread habitats do not differ noticeably in their 16S rRNA gene sequence from each other, not even those from extreme or technical origin (similarity > 98%). Although they might possess various physiological features, different species cannot be recognized on basis of the 16S rRNA gene. A higher resolution was obtained by comparing the sequences of the gene *nxrB*. In contrast to the ubiquitous and phylogenetically ancient NOB genus *Nitrospira*, *Nitrotoga* does not seem to be very diverse so far. However, its high abundance in various environments makes it an important player in nitrification.

## **NAPHTHALENE DEGRADATION BY SULFATE-REDUCING MARINE COMMUNITIES**

S. Wolfson<sup>1</sup>, L.Y. Young<sup>1</sup>

<sup>1</sup>*Environmental Sciences, Rutgers The State University of New Jersey,  
New Brunswick, USA*

### **Background**

Polycyclic aromatic hydrocarbons (PAHs) are ubiquitously distributed to the environment through the extensive petroleum and chemical industries. These toxic chemicals are of concern because of continual, widespread release.

### **Objectives**

The bicyclic hydrocarbon naphthalene undergoes aerobic and anaerobic transformations, however our understanding of the details of anaerobic naphthalene degradation lags behind that of aerobic processes.

### **Methods**

Sediment was obtained from Tuckerton, NJ, where PAHs are introduced through nonpoint deposition to an otherwise relatively pristine ecosystem. Anaerobic enrichment cultures were established with 10% anoxic estuarine sediment under sulfate reducing conditions and amended with 500µM naphthalene as the sole carbon source. Naphthalene concentrations were monitored using GC/FID.

### **Conclusions**

Naphthalene loss was observed in 139 days in primary enrichments, followed by 48 days in transfer cultures. Subsequent transfers receiving 30-50% active cultures are sediment free and degrade naphthalene within 21 days. Stoichiometric loss of 3mM sulfate per 500µM naphthalene is observed. In the presence of molybdate, which inhibits sulfate reduction, no naphthalene degradation occurs, linking sulfate reduction to naphthalene metabolism. Distinct bands unique to naphthalene degrading cultures are seen in 16S rDNA analyzed by DGGE, indicating the enrichment of naphthalene degrading bacteria. By incorporating <sup>13</sup>C-Naphthalene into DNA and RNA via stable isotope probing (SIP), the active microbes responsible for naphthalene degradation can be determined. Additionally, the recovery of 2-naphthoyl-CoA-reductase from <sup>13</sup>C-DNA as well as identification of <sup>13</sup>C intermediates can help to describe the metabolic pathway. This investigation of a robust sulfidogenic marine enrichment culture advances our understanding of the diversity of microbes able to anaerobically degrade naphthalene.

**QUANTIFICATION OF SOIL MICROBIOLOGICAL ACTIVITIES BASED ON CROP TYPE (OAT, TRITICALE)\***

A. Wolinska<sup>1</sup>, A. Szafranek-Nakoneczna<sup>1</sup>, U. Zielenkiewicz<sup>2</sup>, K. Tomczyk-Zak<sup>2</sup>,  
A.M. Banach<sup>1</sup>, M.K. Blaszczyk<sup>3</sup>, Z. Stepniewska<sup>1</sup>

<sup>1</sup>Biochemistry and Environmental Chemistry,  
The John Paul II Catholic University of Lublin, Lublin, Poland

<sup>2</sup>Microbial Biochemistry, Institute of Biochemistry and Biophysics PAS, Warsaw,  
Poland

<sup>3</sup>Microbial Biochemistry, Warsaw University of Life Sciences, Warsaw, Poland

**Background**

Agriculture in Poland has been an important part of the country's economy (about 60% of Poland's total area is used for crop cultivation). It is known, that agricultural types of soil contain much smaller number of microorganisms, in comparison with natural soils. Thus we hypothesised that agricultural soils are biologically degraded and not being able to become naturally regenerated which may lead to their inability of regaining the satisfactory level of fertility.

**Objectives**

The aim of the study was to indicate which type of crop: oat or triticale is more favourable for sustaining soil microbiological activity.

**Methods**

Eight different soil units agriculturally used, and the same number of control soils not agriculturally exploited were studied. Soils were collected in April 2014, using Egner's bow from the surface layer. Under laboratory conditions the following analyses were performed: pH, electric conductivity, total carbon, phosphorus and nitrogen content, microbial biomass (chloroform fumigation), respiration (GC), soil dehydrogenase activity (TTC) and DNA isolation (chloroform extraction method with CsCl<sub>2</sub> gradient). Spearman's rho correlation coefficient was used to assess relationships between chemical and microbiological soil properties.

**Conclusions**

It was demonstrated that cultivated soils are biologically degraded, what was evidenced by lower values of all microbiological parameters in relation to control sites. Comparing crop type we found that triticale is more favourable for sustaining soils microbiological activity rather than oat. Determined positive correlations proved that pH, carbon, phosphorus and nitrogen content are the most important factors determining soil microbiological activities.

*\*Project was financed by the National Science Centre (Poland), granted on the basis of decision DEC-2013/09/D/NZ9/02482.*

## **ENVIRONMENTAL FACTORS INFLUENCED ON SOIL MICROBIOLOGICAL ACTIVITY\***

A. Wolinska<sup>1</sup>, A. Szafranek-Nakoneczna<sup>1</sup>, U. Zielenkiewicz<sup>2</sup>, A. Kuźniar<sup>1</sup>,  
M.K. Błaszczuk<sup>3</sup>, Z. Stępniewska<sup>1</sup>

<sup>1</sup>Biochemistry and Environmental Chemistry,  
The John Paul II Catholic University of Lublin, Lublin, Poland

<sup>2</sup>Microbial Biochemistry, Institute of Biochemistry and Biophysics PAS, Warsaw,  
Poland

<sup>3</sup>Microbial Biology, Warsaw University of Life Sciences, Warsaw, Poland

### **Background**

Many of recent studies have focused on documenting how soil bacterial communities are affected by specific environmental changes or disturbances. It was indicated that vegetation type, carbon and nutrient availabilities, and soil moisture may influence microbial activity at local scales, whilst soil pH seemed to be a better predictor at the continental scale.

### **Objectives**

The aim of the study was to determine effect of selected environmental factors: pH, redox potential (Eh) and total carbon (TC) on soil microbiological activity, expressed as microbial biomass (MB), DNA content, potential ammonification (PA) and most probable number (MPN) of ammonifying bacteria.

### **Methods**

Fifth representatives of *Eutric Cambisols* collected in April 2014 from the surface layer of agricultural sites were investigated. Spearman's rho correlation coefficient was used to determine relationships between environmental and microbiological soil properties.

### **Conclusions**

Positive correlations among pH, TC and all microbiological properties were reported. pH was found to be proportionally related with MB (0.73\*\*), DNA (0.84\*\*\*), PA (0.65\*\*) and MPN (0.73\*\*). Analogical trend demonstrated TC, what was confirmed by values of r coefficients, as follows: MB (0.64\*\*), DNA (0.78\*\*), PA (0.76\*\*), MPN (0.83\*\*\*). In the case of Eh it was noted that its lower values have stimulating effect on microbiological activity in *Eutric Cambisols*, as evidenced by following assigned rho: MB (-0.69\*\*), DNA (-0.83\*\*), PA (-0.75\*\*) and MPN (-0.82\*\*). Among investigated environmental factors only impact of moisture have insignificant character ( $p > 0.05$ ) in relations to tested soil microbiological properties.

*\*Project was financed by the National Science Centre (Poland), granted on the basis of decision DEC-2013/09/D/NZ9/02482.*

**THERMOPHILIC METHANOGENS REDUCE AMORPHOUS FE(III) OXIDES AND GENERATE CRYSTALLINE MAGNETITE ON CELL SURFACES**

C. Yamada<sup>1</sup>, S. Kato<sup>2</sup>, S. Kimura<sup>3</sup>, M. Ishii<sup>1</sup>, Y. Igarashi<sup>1</sup>

<sup>1</sup>Biotechnology, The University of Tokyo, Tokyo, Japan

<sup>2</sup>Bioproduction Research Institute,

National Institute of Advanced Industrial Science and Technology, Sapporo, Japan

<sup>3</sup>Biomaterial Sciences, The University of Tokyo, Tokyo, Japan

**Background**

Methane production is affected by various environmental stimuli including the presence of Fe(III) oxides [1,5]. Inhibitory effect of Fe(III) oxides and Fe(III)-reducing ability in mesophilic methanogens has been reported [2,3]. There have been only limited information about thermophilic methanogens.

**Objectives**

Thermophilic methanogens were investigated for their ability to reduce poorly crystalline Fe(III) oxides (ferrihydrite) and the inhibitory effects of ferrihydrite on their methanogenesis.

**Methods**

*Methanothermobacter thermautotrophicus* strain  $\Delta H^T$ , *Methanosaeta thermophila* strain  $PT^T$ , and *Methanosarcina thermophila* strain  $TM-1^T$  and strain FE-1 were anaerobically cultivated in various methanogenic substrates supplemented media at 55 °C in the presence or absence of ferrihydrite. The amounts of methane and concentrations of Fe(II) were measured by gas chromatography and ferrozine method, respectively.

**Conclusions**

Fe(III) reduction was observed by the thermophilic methanogens only in the presence of  $H_2$  as the reducing source [4]. While addition of ferrihydrite resulted in inhibition of methanogenesis, ferrihydrite reduction by the methanogens partially alleviates the inhibitory effects. *Methanosarcina thermophila* generated magnetite particles on its cell surfaces through ferrihydrite reduction. These findings suggest that interaction between Fe(III) minerals and methanogens has significant impacts on materials and energy cycles in anoxic environments.

<sup>3</sup>*National Institute of Infectious Diseases and Vaccinology, National Health Research Institutes, Miaoli, Taiwan*

### **Background**

Infections caused by treatment-resistant non-albicans *Candida* species, such as *C. tropicalis*, have increased. It has become an emerging challenge in managing fungal infections. Previous researches have showed that *C. tropicalis* are opportunistic yeasts exist in environment.

### **Objectives**

We are interested in whether the opportunistic yeasts may spread from environment into human body.

### **Methods**

We isolated and characterized pathogenic yeasts on the surface of fruits from supermarkets. A total of 291 isolates of 83 species from 24 different types of fruits were recovered. We have determined their species and drug susceptibility.

### **Conclusions**

Of the 83 species, 7 common pathogenic *Candida* species were detected. They included 16 *C. guilliermondii*, 15 *C. famata*, 3 each of *C. parapsilosis* and *C. tropicalis*, 2 each of *C. krusei*, *C. lusitaniae* and *C. orthopsilosis*. The drug susceptibilities of 162 of the 291 isolates were determined. Totally, 158 (97.5%), 104 (64.2%), and 102 (63%) isolates were susceptible to amphotericin B (MICs  $\leq$  4 mg/l), fluconazole (MICs  $\leq$  8 mg/l), and triadimenol (MICs  $\leq$  8 mg/l), respectively. One *C. tropicalis* isolate (F91) from wax apple had MICs at 64 mg/l for both fluconazole and tridimenol. It belongs to diploid sequence type (DST) 149, a genotype found in isolates from human as well as soil. Hence extra caution shall be taken when providing fruits or juice to severely immunocompromised patients since drug resistant pathogenic yeasts may be on the surface of fruits.

## **BIOREDUCTION OF TELLURIUM AND SELENIUM OXYANIONS BY UNACCLIMATED ANAEROBIC GRANULAR SLUDGE**

V. Yarlagadda<sup>1</sup>, P.N.L. Lens<sup>1</sup>

<sup>1</sup>EEWT, UNESCO\_IHE, Delft, Netherlands

### **Background**

Microbial reduction of chalcogen oxyanions such as tellurite and selenite is promising for development of innovative biotechnological processes for applications in bioremediation, wastewater treatment and production of functional nanomaterials.

### **Objectives**

Here, we demonstrate rapid and stable bioreduction of tellurite, for the first time, using unacclimated anaerobic granular sludge, obtained from an operating upflow anaerobic granular sludge blanket reactor treating paper mill wastewater. In addition, bioreduction of tellurite in the presence of selenite was determined.

### **Methods**

Bioreduction experiments were performed in serum bottles under different growth conditions using anaerobic granular sludge as source of microorganisms. Bioreduction of selenium and tellurium oxyanions profiles were determined at regular time intervals. Biochemical and microbial characterization of selenium and tellurium oxyanions reducing granular sludge was determined.

### **Conclusions**

Tellurite was rapidly reduced to brown and then to black colored elemental tellurium by anaerobic granular sludge. The reduction of tellurite occurred at a much faster rate than the selenite when supplied individually. Complete reduction of 1 mM of tellurite and selenite was observed in 8 and 96 h, respectively. When both tellurite and selenite were present in the medium, the reduction of tellurite was not significantly affected. But, selenite reduction was found to be slower in the presence of tellurite. It is interesting to note an overlap between the reduction of both tellurite and selenite, which is needed for production of Se-Te functional nanomaterials. Repeated bioreduction of 1 mM of tellurite was sustainable during multiple cycles of feeding in a fed-batch experiment, indicates the applicability in biological treatment and formation of Te based nanomaterials.

**MICROBIAL ASSOCIATIONS RELATED TO METHANE PRODUCTION IN AN UP-FLOW ANAEROBIC SLUDGE BLANKET TREATING MOLASSES WASTEWATER**

J. Yun<sup>1</sup>, T.G. Kim<sup>2</sup>, K.S. Cho<sup>1</sup>

<sup>1</sup>*Department of Environmental Science and Engineering, Ewha Womans University, Seoul, Korea*

<sup>2</sup>*Ecological Information Management Team, National Institute of Ecology, Choongnam, Korea*

**Background**

Anaerobic digestion of organic wastes involves complex microbial interactions. The understanding of microbial interactions in anaerobic digestion can be utilized to construct strategies for methane production stably and effectively.

**Objectives**

In this study, methane production was evaluated in the up-flow anaerobic sludge blanket (UASB) reactor using molasses wastewater, and the active bacterial and archaeal communities were characterized using rRNA-based ion torrent sequencing.

**Methods**

The UASB reactor achieved a stable process performance at an organic loading rate of 1.7~13.8 g-COD·L<sup>-1</sup>·d<sup>-1</sup> (87–95% COD removal efficiencies), and the maximum methane production rate was 4.01 L-CH<sub>4</sub>·L<sup>-1</sup>·d<sup>-1</sup> at 13.8 g-COD·L<sup>-1</sup>·d<sup>-1</sup>. Community analysis revealed that bacterial and archaeal communities shifted along with OLR, and *Lactococcus* and *Methanosaeta*, comprising up to 84% and 80% of the respective communities, drove the changes. Microbial network analysis was applied to identify associations among the relative abundances of bacterial and archaeal operational taxonomic units, environmental parameters, and reactor performance. The constructed network (average shortest path, 2.261; clustering coefficient, 0.514) revealed the prevalence of bacteria–archaea associations (50% of microbe–microbe associations) and contained seven microbial hub nodes including both bacterial and archaeal nodes. Interestingly, the *Lactococcus* and *Methanosaeta* were network hub nodes and positively correlated. In addition, they shared the other microbial hub nodes as neighbors and were positively correlated with methane production.

**Conclusions**

The results indicate that the close association between *Lactococcus* and *Methanosaeta* is responsible for the stable production of methane in the UASB reactor using molasses wastewater.

<sup>4</sup>Sustainable Agro-Ecosystems and Bioresources Department, IASMA Research and Innovation Centre Fondazione Edmund Mach, San Michele all'Adige (TN), Italy

### **Background**

Soil chemical and physical properties, which are determined both by pedo-climatic factors and by management, can significantly influence microbial communities.

### **Objectives**

Scope of this work was to assess whether given features can specifically influence defined microbial taxa in a man-managed environment such as the vineyard.

### **Methods**

Soil samples were collected in 12 vineyards located in two neighbouring groups of hills, both renowned in Italy for their wines: the Euganean Hills, whose soils are of prevalent volcanic origin, mainly from trachyte and riolite rocks, and the Berici Hills, with a marine sedimentary genesis, mainly from clay-limestone. Soil bacterial and fungal communities were determined through 16S and ITS 454 pyrosequencing analysis, their relative taxa abundances were calculated and their levels of correlation with soil characteristics were tested.

### **Conclusions**

In order of abundance, the dominant bacterial taxonomic groups across all samples were Actinobacteria, Alphaproteobacteria, Acidobacteria, Bacteroidetes, Betaproteobacteria, Chloroflexi, Gemmatimonadetes, Planctomycetes,

Deltaproteobacteria, Gammaproteobacteria. Among fungal phyla, Ascomycota largely dominated followed by Basidiomycota. Prevailing fungal classes were Dothideomycetes, Sordariomycetes, Agaromycetes, Leotiomycetes, Eurotiomycetes and Tremellomycetes. Some of these taxa and less abundant microbial groups were found to be significantly influenced by soil pH and texture. Moreover, a considerable number of significant correlations were found between the relative abundance of microbial taxa and the amount of several different chemical parameters such as total carbon, nitrogen, phosphorus, exchangeable bases and microelements.

This study provides novel insights into how soil structure and management can affect soil microbial community composition.

## EFFECT OF BIOAUGMENTATION WITH BACTERIAL STRAINS ISOLATED FROM THE SOIL OF RICE FIELDS ON COMPOSTING PROCESSES USING RICE STRAW AND SEWAGE SLUDGE

J. Zueco<sup>1</sup>, L. Marimon Vicent<sup>2</sup>, M. Iranzo Rodenas<sup>1</sup>, S. Mormeneo Bernat<sup>1</sup>,  
R. Boluda Hernández<sup>2</sup>

<sup>1</sup>Microbiology. Fac Pharmacy, University of Valencia, Burjassot, Spain

<sup>2</sup>Plant Biology (SOREiMA). Fac Pharmacy, University of Valencia, Burjassot, Spain

### Background

Composting is a biotransformation process in which solid organic matter turns into mature and stabilized material by the action of microorganisms in an aerobic process. Microorganisms play a key role in composting; the performance of the process and the quality of the final product depends on the quantitative and qualitative composition of microbial communities associated to the different stages of the process.

### Objectives

In this work, we describe the use of two bacterial strains, *Paenibacillus barcinonensis* and *Bacillus* sp. BP7, isolated from the soil of rice fields in the Ebro river delta in Spain, as bioaugmentants in composting processes using rice straw and sewage sludge as starting material.

### Methods

Composting piles were created by blending sewage sludge and rice straw at a ratio of 2.6:1 (w/w fresh weight) with a moisture content of 60%. To test the effect of the two strains, individual piles were seeded with 10<sup>8</sup> ufc/gram of either *P. barcinonensis* or *Bacillus* sp. BP7, and a series of parameters were determined during the composting process

### Conclusions

Among the parameters determined, the humification index after 25 days had increased 40% in the piles supplemented with *P. barcinonensis* and 20% in those supplemented with *Bacillus* sp. BP7, a clear indicator of the efficiency of the bioaugmentation. This was also accompanied, in the case of *P. barcinonensis*, by a change in the humic/fulvic acids ratio that went from 3.2 after 25 days in the control pile to 5.2 in the case of *P. barcinonensis*. These results suggest the potential application of bioaugmentation in composting.

Conselleria de Agricultura Pesca y Alimentación, Burjassot, Spain

### **Background**

Pharmaceutical and personal care products (PPCPs) discharged with wastewater treatment plant effluents are an emerging surface water quality concern. Ibuprofen is the most widely used member of a diverse class of pharmaceuticals termed non-steroidal anti-inflammatory drugs (NSAIDs), many of which share a phenylacetic acid (PAA) core. Ibuprofen has been detected in bodies of water worldwide. Investigations into its environmental impact have found that ibuprofen induced changes on fish, plants, algae and microbial aquatic communities at environmentally relevant concentrations.

### **Objectives**

The aim of this research was the isolation of bacteria with characteristics for potential bioaugmentation to enhance ibuprofen degradation in wastewater treatment plants and in the sewage sludge resulting from the activity of these plants.

### **Methods**

Composting piles spiked with ibuprofen were created by blending sewage sludge and rice straw at a ratio of 2.6:1 (w/w fresh weight) with a moisture content of 60% to which a concentration of 1g/l of ibuprofen was added. Samples were taken at different days in the different phases, up to 42 days when ibuprofen had been completely degraded. Microorganisms extracted from these samples were tested in minimal medium supplemented with 500 mg/ml of ibuprofen and incubated at 24°C or 55°C, to discriminate mesophilic from thermophilic microorganisms.

### **Conclusions**

Ibuprofen degradation occurred only in the samples incubated at 24°C. Plating of microorganism from these samples allowed the isolation of some 30-40 different colony morphologies that were again tested for ibuprofen degradation. Two of the isolates were confirmed to degrade ibuprofen and were partially characterized as belonging to the genus *Klebsiella*.

**DEVELOPMENT OF A TEST FOR THE DETECTION OF BACILLUS THURINGIENSIS VAR KURSTAKI IN ENVIRONMENTAL SAMPLES**

*P. Mengual Buigues<sup>1</sup>, M. Cholvi Calduch<sup>2</sup>, C. Martínez Navarro<sup>2</sup>, J. Zueco<sup>2</sup>*

<sup>1</sup>Rgto. NBQ I. Valencia, Ministerio de Defensa, Paterna, Spain

<sup>2</sup>Microbiology. Fac Pharmacy, University of Valencia, Burjassot, Spain

**Background**

*Bacillus thuringiensis* was isolated for the first time in 1902 from diseased silkworm larvae and its commercial use as an ecological insecticide started in 1958. *B. thuringiensis* var *kurstaki* (*Btk* for short) is routinely used to control caterpillar pests both at large extensions and at small gardens. The crystal toxin is only active when ingested by the caterpillars and absorbed in the alkaline digestive tract. The toxin has a relatively narrow spectrum of action and does not affect mammals birds or other insects and besides, the persistence of *Btk* on foliage is of around five days and does not accumulate on the environment. Because of its relative safety *Btk* has also been in use as a simulant by armed and security forces in exercises of response to biological or bioterrorist attacks.

**Objectives**

In this work we have developed rapid tests that can be used for the detection of the presence of *Btk* on air or surface samples after controlled release, and to measure the efficiency of decontamination measures.

**Methods**

Polyclonal antibodies were raised in rabbits by injecting them with autoclaved commercial *Btk* spores.

**Conclusions**

Immune response was confirmed by Western-Immunoblot and immunofluorescence assays and the specific IgGs, after purification by affinity chromatography using *Btk* spores, were coupled to polystyrene beads, to develop a slide agglutination test, colloidal gold, as part of lateral flow immunochromatography tests, or polystyrene ELISA plates, to develop ELISA based assays. Preliminary results confirm the validity of slide agglutination test whilst lateral flow and ELISA are under development.

## **MOLECULAR IDENTIFICATION OF MICROORGANISMS USED FOR „BACTERIOGRAPHIE“**

S. Mayrhofer<sup>1</sup>, P. Brada<sup>1</sup>, C. Ukowitz<sup>1</sup>, E. Schopf<sup>2</sup>, M. Zunabovic<sup>1</sup>, K.J. Domig<sup>1</sup>

<sup>1</sup>*University of Natural Resources and Life Sciences Vienna Department of Food Science and Technology, Institute of Food Science, Vienna, Austria*

<sup>2</sup>*University of Veterinary Medicine Vienna Department of Farm Animal and Public Health in Veterinary Medicine,  
Institute of Meat Hygiene Meat Technology and Food Science, Vienna, Austria*

### **Background**

The knowledge that bacteria use pigments to guard against UV radiation gave Erich Schopf the idea of using bacteria as unique tool for creating colors. Instead of painting artists' colors on different painting supports, he applies bacteria on agar-based media. Initially invisible, the picture gets visible due to the growth of the bacteria used. Erich Schopf has called this technique 'Bacteriographie' ([www.bacteriographie.com](http://www.bacteriographie.com)).

Meanwhile the ensemble of bacteria used for 'Bacteriographie' comprises around 900 microorganisms from different regions of the world (e.g. Austria, Germany, Greenland, Iceland, India, Indonesia, Ireland). They were collected from air, food, water, soil and recently also from holy water. Next to their ability to form pigments a general criterion is their growth at room temperatures within a foreseeable time period. Additionally, they have to undergo strict screening tests to perceive their suitability.

### **Objectives**

Although some classical microbiological tests were done to get more information about the microorganisms themselves, the identity of the isolates is generally not known. Thus, this study focused on their identification at species-level using molecular biological methods.

### **Methods**

A subset of the most important isolates (n = 120) was identified by 16S rRNA gene sequencing.

### **Conclusions**

About 40 different genera could be identified. The relation between gram-positive and gram-negative species was nearly balanced. However, also a few fungal species (e.g. *Pseudozyma* spp., *Cryptococcus* spp.) were identified. Different species of the genera *Pseudomonas*, *Flavobacterium*, *Microbacterium*, *Rhodococcus*, *Kocuria*, *Chryseobacterium* and *Arthrobacter* were frequently detected, which form yellow, orange and red pigments.

**RAPID RECOVERY OF CYANOBACTERIAL PIGMENTS IN DESICCATED BIOLOGICAL SOIL CRUSTS FOLLOWING ADDITION OF WATER**

R. Abed<sup>1</sup>, L. Polerecky<sup>2</sup>, A. Al-Habsi<sup>1</sup>, J. Oetijen<sup>3</sup>, M. Strous<sup>4</sup>, D. de Beer<sup>2</sup>

<sup>1</sup>Biology, Sultan Qaboos University, Muscat, Oman

<sup>2</sup>Microsensor, Max-Planck Institute, Bremen, Germany

<sup>3</sup>MALDI Imaging Laboratory, Bremen University, Bremen, Germany

<sup>4</sup>Department of Geosciences, University of Calgary, Calgary, Canada

**Background**

Cyanobacteria in biological soil crusts were shown to move upwards in to track water, however this it is not known how widespread this process is in other crusts.

**Objectives**

To examine soil surface colour change to green and hydrotaxis following addition of water to crusts

**Methods**

We used pigment extraction, hyperspectral imaging, microsensors and <sup>13</sup>C labelling experiments coupled to matrix-assisted laser desorption and ionization time of flight-mass spectrometry (MALD-TOF MS)

**Conclusions**

The topsoil colour turned green in less than 5 min following water addition. The concentrations of chlorophyll *a*, scytonemin and echinenon rapidly increased in the top <1 mm layer while in the deeper layer their concentrations remained low. Hyperspectral imaging showed that, in both wet and dehydrated crusts, cyanobacteria formed a layer at a depth of 0.2-0.4 mm and this layer did not move upward after wetting. <sup>13</sup>C labelling experiments and MALDI TOF analysis showed that Chl *a* was already present in the desiccated crusts and *de novo* synthesis of this molecule started only after 2 days of wetting due to growth of cyanobacteria. Microsensor measurements showed that photosynthetic activity increased concomitantly with the increase of Chl *a*, and reached a maximum rate approximately 2 hours after wetting. We conclude that the colour change of soil crusts to green upon water addition was not due to hydrotaxis but rather to the quick recovery and reassembly of pigments.

## **GEOMICROBIOLOGY OF JAZAN SABKHA, SAUDI ARABIA**

M. Albokari<sup>1</sup>, I. Mashhour<sup>1</sup>, M. Alshehri<sup>1</sup>

<sup>1</sup>Nuclear Science Research Institute (NSRI),

King Abdulaziz City for Science and Technology (KACST), Riyadh, Saudi Arabia

### **Background**

Sabkha is a unique environment of economic and geologic importance with a valuable resource of distinctive features. Saudi Arabia possesses coastal Sabkhas which are extensively distributed along both the eastern and western areas.

### **Objectives**

Therefore, samples (I and II) with depth of 50 cm were collected from a remote salt marsh at the southwest of Saudi Arabia, which is called Jazan Sabkha, to unveil the bacterial community that survive in such extreme environment.

### **Methods**

Each sample was cut horizontally at interval of 1 cm for the first 10 cm and at 5 cm for the next 20 cm. The samples are considered salty and sulphurous, where sodium and soluble chloride at the range of 11,000-34,000 ppm and 11,000-99,000 ppm, respectively, while sulfate varied from 2,070 to 18,8200 ppm. Next generation sequencing (454 pyrosequencing) was applied to determine the bacterial communities inhabiting each layer.

### **Conclusions**

Overall, *Pseudomonas* Genus was dominated in both samples with 46% and 39% for I and II, respectively. *Pseudomonas putida* was identified in each cross-section at 1cm with variable percentages. In addition, *P. veroniim*, *P. cannabina* and *Herbaspirillum rubrisubalbicans* were presented with less percentages. *Leptospirillum* spp. were detected at lower layers and at they were optimized between 15-20 cm while *Methylobacterium tardum* appeared at their maximum around 7-9 cm. Most of genera saline species of *Halobacteriaceae* family like *Halorhabdus* spp., *Halonotius* spp., *Halobaculum* spp., *Halomicrobium* spp. *Halorubrum* spp., *Halogranum* spp., *Haloplanus natans*, *Salinibacter* spp. and *Natronomonas* spp. were detected within 1-2 cm near to the salty crusty surface of Sabkah.

**CONSTRUCTION OF PUC19 PLASMID METAGENOMIC LIBRARY FOR EXPLORING NOVEL PROTEASE ENZYMES FROM LAKE ACIGOL, A HYPERSALINE LAKE IN SOUTHERN, TURKEY**

N. Balci<sup>1</sup>, M. Menekşe Kılıç<sup>2</sup>, N. Gül Karagüler<sup>2</sup>

<sup>1</sup>*Department of Geology and Geological Engineering, Istanbul Technical University, Istanbul, Turkey*

<sup>2</sup>*Faculty of Science and Letters Department of Molecular Biology and Genetics, Istanbul Technical University, Istanbul, Turkey*

**Background**

Investigations of extreme environments are important for the study of evolution relationships, discovery of new species and various ecological relations among organisms. Besides, new metabolites and novel enzymes, metabolic pathways of organisms' can be discovered from extreme environments.

**Objectives**

In this study, metagenomics approach is used to isolate potential biotechnological novel enzymes from Lake Acıgöl. Especially we have focused on proteases which are ubiquitous enzymes and they have crucial roles in different industrial applications. Research area Lake Acıgöl is located between Afyon, Denizli and Burdur city boundaries in Aegean region, Turkey. It is a good example for extreme environments due to its high salinity (about 200g/L NaCl) which makes the lake suitable for halophilic microorganisms.

**Methods**

Bacterial population of Lake Acıgöl have already been identified and Lake bacterial population consist of 38.8% Uncultured Bacterium, 30.8% Firmucutes, 15.3% Bacterioidetes, 7.6% Gammaproteobacterium and 7.6% Deltaproteobacterium. Because of the high population of uncultured microorganisms Lake Acıgöl is a potential candidate for novel enzyme exploration. To isolate extremophilic protease enzymes from Lake Acıgöl sediment samples were collected from different part of the Lake and Metagenom (DNA) isolation was carried out by manually according to Zhou et. Al., 1999 [1].

**Conclusions**

Metagenom library was constructed by using *pUC19 plasmid*. Screening studies for possible protease enzymes will be carried out using 1% of skim milk LB agar plates and Salt Tolerance Screening Method according to Culligan et. Al., 2013 [2].

**CUPRIAVIDUS METALLIDURANS CH34 PHYSIOLOGY AND INTERACTIONS WITH BASALT ON EARTH AND IN SPACE**

B. Byloos<sup>1</sup>, R. Van Houdt<sup>1</sup>, I. Vyacheslav<sup>2</sup>, N. Boon<sup>3</sup>, N. Leys<sup>1</sup>

<sup>1</sup>Microbiology Unit, SCK•CEN, Mol, Belgium

<sup>2</sup>Medical and Biological Problems (IMBP), Russian Academy of Sciences (RAS), Moscow, Russia

<sup>3</sup>Laboratory of Microbial Ecology and Technology, University of Ghent, Ghent, Belgium

**Background**

Microbe-mineral interactions have become of interest for space exploration as microbes can biomine useful elements from planetary regolith, which could serve as nutrients in a life support system.

**Objectives**

Therefore, this research aimed to assess the impact of space conditions on physiology of *Cupriavidus metallidurans* CH34 and identifying the molecular mechanisms behind microbe-mineral interactions on basalt, a lunar-type rock.

**Methods**

Survival of *C. metallidurans* CH34 was monitored after a 3-month period in mineral water with or without basalt by plate counts, flow cytometry, ICP-MS and microscopy. The effect of space conditions was studied via a flight experiment on board the Russian PHOTON-M4 capsule.

**Conclusions**

The results obtained from ground experiments showed that the cultivable fraction dropped to 10% indicating a transition to a more dormant state. In the presence of basalt, CH34 remained viable, attached and formed a biofilm. The space flight experiment indicated more viable cells compared to the ground experiment both in the absence and presence of basalt, indicating a positive effect of space flight on survival.

Additional physiological and molecular analyses are on-going to confirm these observations and to determine the molecular processes.

Acknowledgments: This work is supported by the European Space Agency (ESA-PRODEX) and the Belgian Science Policy (Belspo) through the E-GEM/BIOROCK project. We thank Kai Finster and Charles Cockell for the coordination of the BIOROCK project.

**MEMBRANE-BOUND AMYLOPULLULANASE IS ESSENTIAL FOR STARCH METABOLISM OF SULFOLOBUS ACIDOCALDARIUS DSM639**

K.H. Choi<sup>1</sup>, J. Cha<sup>1</sup>

<sup>1</sup>Microbiology, Pusan National University, Busan, Korea

**Background**

The growth of *Sulfolobus* shows that these species prefer starch or long-chain maltooligosaccharides to maltose as a carbon source and have both  $\alpha$ -amylase and  $\alpha$ -glucosidase activities. The annotation of the genome sequence of *S. acidocaldarius* assume that the gene encoding amyolytic enzyme, Saci\_1162, within the putative maltose/maltodextrin ABC transporter operon (*Saci\_1160* to *Saci\_1166*) is involved in the degradation of starch or  $\alpha$ -linked polymers into small maltooligomers.

**Objectives**

A putative amyolytic enzyme, Apu (Saci\_1162), was characterized whether it is involved in the starch metabolism in *S. acidocaldarius*.

**Methods**

The physiological role of Apu in starch metabolism was investigated by the growth and starch degradation pattern of *apu* disruption mutant as well as biochemical properties of recombinant Apu.

**Conclusions**

The  $\Delta$ *apu* mutant lost the ability to grow in minimal medium in the presence of starch, and the amyolytic activity observed in the membrane fraction of the wild-type strain was not detected in the  $\Delta$ *apu* mutant when the cells were grown in YT medium. The purified membrane-bound Apu initially hydrolyzed starch, amylopectin, and pullulan into various sizes of maltooligosaccharides, and then produced glucose, maltose, and maltotriose in the end, indicating Apu is a typical endo-acting amylopullulanase which belongs to glycosyl hydrolase family 57. The maltose and maltotriose observed in the culture medium during the exponential and stationary phase growth indicates that Apu is the essential enzyme to initially hydrolyze the extracellular starch into small maltooligosaccharides to be transported into the cell.

<sup>6</sup>Escuela de Química & Centro de Investigaciones en Productos Naturales (CIPRONA), Universidad de Costa Rica, San José, Costa Rica

**Background**

Río Sucio ('Dirty river') in Braulio Carrillo National Park (Costa Rica) is a river of volcanic origin that possesses a characteristic yellow color due to the presence of high amounts of mineral deposits from Irazu Volcano.

**Objectives**

To perform a physicochemical characterization of the Río Sucio water and to analyze the impact of these parameters on the microbial community that inhabits the river.

**Methods**

Physicochemical analysis was performed by ion-exchange chromatography (IC), inductively coupled plasma mass spectrometry (ICP-MS), scanning electron microscopy with electron dispersive spectrometer (SEM-EDS) and X-ray diffraction (XRD). Analysis of the microbial community was performed by analysis of the V5-V6 hypervariable regions of the 16S rRNA gene. PCR amplicons were sequenced on a Illumina MiSeq instrument and the sequences compared against the RDP database (Ribosomal Database project – <http://rdp.cme.msu.edu/>).

**Conclusions**

Physicochemical analysis revealed that Río Sucio is a slightly acidic river (pH 5.0) containing high concentrations of sulphate ( $502 \pm 29$  mg/L), calcium ( $96.6 \pm 2.2$  mg/L), magnesium ( $27.36 \pm 0.16$  mg/L), aluminium ( $17.1 \pm 1.9$  mg/L) and iron ( $5.20 \pm 0.11$  mg/L). The precipitated material in the bottom of the river was composed mainly of iron oxides, as indicated by SEM-EDS and XRD. Microbial diversity analysis showed that the most abundant organisms are closely related to sulfur, thiosulphate and iron oxidizing bacteria such as *Sulfuritalea* spp., *Ferrovum* spp., *Acidithiobacillus ferrooxidans*, *Leptospirillum ferrooxidans* and *Ferrithrix* spp. These observations suggest that Río Sucio has an acid rock drainage environment where the chemical composition is biologically driven by sulfur and iron oxidizing bacteria.

<sup>2</sup>Chemistry, U.S. Naval Research Laboratory, Washington DC, USA

<sup>3</sup>Center for BioMolecular and Material Science Engineering, U.S. Naval Research Laboratory, Washington DC, USA

<sup>4</sup>Acoustics, U.S. Naval Research Laboratory, Washington DC, USA

<sup>5</sup>Geosciences, U.S. Naval Research Laboratory, Stennis Space Center MS, USA

#### Background

Biological systems are frequently exposed to microwave radiation. Many studies have investigated the influence of microwaves on these systems, but controversy over methods to distinguish between thermal and non-thermal microwave effects remains.

#### Objectives

To differentiate between non-thermal and thermal microwave effects on a physiology of a microorganism, a thermophilic bacterium was grown in a constant-temperature microwave or a convection oven. Comparing the growth properties of the thermophile in these conditions will reveal non-thermal microwave effects on cell growth and

physiology. Biophysical and biochemical analysis will demonstrate changes in morphology and chemical composition arising from microwave exposure.

### **Methods**

Cell growth was analyzed by optical density (OD) measurements (supported by independent quantitative DNA analysis), and cell morphologies were characterized using electron microscopy imaging (SEM, TEM), dynamic light scattering (DLS), and atomic force microscopy (AFM). AFM was also used to probe the biophysical characteristics of the cells, in conjunction with nano-infrared spectroscopy (Nano-IR). Attenuated total reflectance infrared spectroscopy (ATR-IR) and fatty acid methyl ester (FAMES) analysis were used to determine biochemical differences between cells grown in microwave and oven conditions.

### **Conclusions**

Thermophilic bacteria were grown in a synthetic microwave such that thermal effects and microwave effects were distinguishable. These data demonstrate that there are physiological differences between cells cultured in a dielectric field and a convection oven, and that microwaves induce non-thermal changes to the structure, physiology, and chemical composition of the organism.

**DO THE PROTEINS INDUCED BY HIGH HYDROSTATIC PRESSURE IN FUNGI  
PLAY A ROLE IN TOLERANCE TO PRESSURE?**

A. Krishnaswamy<sup>1</sup>, S. Damare<sup>1</sup>

<sup>1</sup>*Biological Oceanography Division, CSIR-National Institute of Oceanography, Panjim, India*

**Background**

Deep-sea is a fascinating environment, which inspite of the extreme conditions of pressure, temperature and nutrients, is home to many life-forms. In order to survive here, the organisms need to develop mechanisms to counter these conditions. Fungi, one of the most ubiquitous eukaryotic forms of life, have also been reported from deep-sea sediments. In order to survive, they undergo both morphological and biochemical adaptations. Induction of proteins is one such response elicited by fungi for survival.

**Objectives**

In our study to understand the mechanism of survival by fungi occurring in deep- sea conditions, we are looking for proteins expressed by fungi and their role in tolerance to high hydrostatic pressure using LCMS QToF.

**Methods**

To understand the mechanism of survival of fungi, in deep- sea conditions, we examine tryptic digests of proteins expressed under various hydrostatic pressure using LCMS QToF.

**Conclusions**

The results showed that some proteins were up-regulated whereas some were down-regulated at higher pressures. Some over-expressed proteins, probably playing a role in pressure tolerance were 30 KDa heat shock protein and heat shock protein SSC1 mitochondrial. Unfortunately, none of the up-regulated proteins could be considered as ones produced exclusively in response to high hydrostatic pressure as all are reported in response to other stresses also. Along with these proteins, there were several hypothetical proteins to which no function has been assigned so far. These could well prove to be the ones limited to pressure stress, which needs to be investigated further by either inactivating the proteins or using knock-down mutations.

B. Asadi<sup>1</sup>, S.H. Motamedi<sup>1</sup>, A. Ventosa<sup>3</sup>

<sup>1</sup>*Extremophiles Laboratory Department of Microbiology,  
Faculty of Biology and Center of Excellence in Phylogeny of Living Organisms College  
of Science University of Tehran, Tehran, Iran*

<sup>2</sup>*Department of Biology, Faculty of Sciences Ferdowsi University of Mashhad,  
Mashhad, Iran*

<sup>3</sup>*Department of Microbiology and Parasitology,  
Faculty of Pharmacy University of Sevilla, Sevilla, Spain*

**Background**

Urmia Lake in the Northwest of Iran is the second largest hypersaline lake in the world which has been explored with great haloarchaeal diversity. Extreme halophilic Archaea are widely distributed in hypersaline habitats.

**Objectives**

During the course of biodiversity studies in Urmia Lake, several new extreme halophilic Archaea were isolated. Amongst them we chose strain DC8<sup>T</sup> for further characterization.

**Methods**

Strain DC8<sup>T</sup> has been characterized taxonomically using polyphasic approach. According to minimal standards we performed Molecular, biochemical, morphological and physiological tests for characterization.

**Conclusions**

16S rRNA gene sequencing showed that strain DC8<sup>T</sup> is a member of the family *Halobacteriaceae*; however, its similarity was as low as 90.1% and 89.3% to haloarchaeal taxa including *Halosimplex* and *Halobaculum* type species, respectively. The cells of strain DC8<sup>T</sup> were non-motile and pleomorphic and needs at least 2.5 M NaCl and 0.02 M MgCl<sub>2</sub> for growth. Optimal growth was at 4.0 M NaCl and 0.1 M MgCl<sub>2</sub>. The optimum pH and temperature for growth were pH 7.5 and 45°C. The G+C content of its DNA is 68.1 mol%. Polar lipid analyses revealed that strain DC8<sup>T</sup> contains phosphatidylglycerol, phosphatidylglycerol phosphate methyl ester and phosphatidylglycerol sulphate. The only quinone present was MK-8 (II-H<sub>2</sub>). The physiological, biochemical and phylogenetic differences between strain DC8<sup>T</sup> and other previously described genera of extremely halophilic archaea suggest that this

strain represents a novel species in a new genus within the family *Halobacteriaceae*, for which the name *Halositis urmiana* gen. nov., sp. nov. is proposed.

**FEMS-1534**

**LIFE ON THE EDGE: PROTEOBACTERIA AND HALOARCHAEA DOMINATE THE MICROBIAL COMMUNITY OF AN EXTREMELY HIGH ALTITUDE LAKE, LAKE LLULLAILLACO (6170 M)**

*C. Dorador<sup>1</sup>, P. Aguilar<sup>1</sup>, T. Bower<sup>2</sup>, M. Farson<sup>2</sup>*

<sup>1</sup>*Departament of Biotechnology, University of Antofagasta, Antofagasta, Chile*

<sup>2</sup>*Department of Anthropology, California State University, Fresno, USA*

**Background**

Despite the crucial role of microorganisms in lake ecosystem function, they are typically poorly studied in high altitude ecosystems. In general, there are few reports of microbial diversity in lakes located at altitudes >5000 m. Lake Llullaillaco is a previously undescribed lake located at 6170 m on the Chilean side of the Llullaillaco volcano, the second highest volcano in the world (6739 m).

**Objectives**

The aim of this study was to describe the basic morphology of Lake Llullaillaco and the microbial diversity from water samples taken from the lake in February 2013.

**Methods**

Bacterial cultures were obtained using different culture media and microbial diversity was analysed by the pyrosequencing of 16S rRNA genes of Bacteria and Archaea. At the time of sampling, the lake had an area of 0.9 ha and maximum depth of 6.8 m. Water temperature ranged between 2 and 5°C and pH was 6.5. 24 bacterial isolates were obtained belonging to the Alpha-, Beta-, Gammaproteobacteria and Actinobacteria. Bacterial diversity was dominated by Proteobacteria (86.5%), Actinobacteria (11.9 %) and Bacteroidetes (1.4%), with Beta-, and Alphaproteobacteria being the most abundant taxa. Archaeal diversity was dominated by Euryarchaeota and the Halobacteriaceae, with a high contribution of unidentified sequences.

**Conclusions**

This study is the first description of microbial diversity in Lake Llullaillaco: diversity was low and characterized by a combination of phylotypes previously described from cold environments and a series of undescribed microorganisms.

**MICROBIAL DIVERSITY IN ARMENIAN SALINE-ALKALINE SOILS AND SUBTERRANEAN SALT DEPOSITS ANALYZED BY MOLECULAR AND CULTURE-BASED METHODS**

A. Hakobyan<sup>1</sup>, H. Panosyan<sup>1</sup>, A. Trchounian<sup>1</sup>, N.K. Birkeland<sup>2</sup>

<sup>1</sup>Microbiology Microbes and Plants Biotechnology, Yerevan State University, Yerevan, Armenia

<sup>2</sup>Department of Biology and Centre for Geobiology, University of Bergen, Bergen, Norway

**Background**

One of the main directions of microbial ecology of extremophiles is the study of halophilic microorganisms' biocenoses, which are mainly found in saline lakes and other water systems as well as saline soils and salt mines. Microbial biodiversity of salt mines and saline-alkaline soils distributed on the territory of Armenia is still poor investigated.

**Objectives**

The aim of the present study was to investigate the microbial composition of saline-alkaline soils of the Ararat Plain and Avan subterranean salt deposits in Armenia.

**Methods**

For this study, clone-library construction of PCR-amplified 16S rRNA genes, DGGE-PCR fingerprinting and cultivation-dependent methods were used. 16S rRNA gene clone libraries and PCR-DGGE fingerprinting sequences were generated from total DNA extracts using universal archaeal and bacterial oligonucleotide primer sets.

**Conclusions**

Sequence analysis of bacterial and archaeal clone libraries and DGGE-PCR products from the samples indicated a dominance of *Firmicutes* and *Euryarchaeota* from the bacterial and archaeal domains, respectively. Several aerobic chemoorganotrophic endospore-forming bacteria were isolated from the salt samples and identified as representatives of the genus *Halobacillus*, *Piscibacillus*, *Virgibacillus* and *Streptomyces*. Five halophilic archaeal strains were isolated from salt stone samples. Four of the archaeal strains were most closely related to members of the genus *Haloarcula* (97-99 % similarity) and one strain most closely to the genus *Halarchaeum* (<97% similarity), indicating that Avan salt mine harbors a unique community of possible novel species.

The work was supported by the CPEA-2011/10081 grant from the Norwegian Cooperation Programme in Higher Education with Eurasia.

**Extreme environments**

**COPQ, A NOVEL FAMILY OF SMALL SECRETED PROTEINS WITH PUTATIVE RADICAL-SCAVENGING AND METAL-DETOXIFYING ACTIVITIES, ARE STRICTLY CONFINED TO THE GENERA RALSTONIA AND CUPRIAVIDUS**

*P. Janssen*<sup>1</sup>, *R. Van Houdt*<sup>1</sup>, *K. Mijndendonckx*<sup>1</sup>, *P. Monsieurs*<sup>1</sup>, *N. Leys*<sup>1</sup>,  
*C. Ouzounis*<sup>2</sup>

<sup>1</sup>*Molecular and Cellular Biology - Unit of Microbiology Institute for Environment Health and Safety (EHS), SCK•CEN, Mol, Belgium*

<sup>2</sup>*Biological Computation & Process Laboratory CERTH, SCK•CEN, Thessalonica, Greece*

**Background**

The soil bacterium *Cupriavidus metallidurans* CH34 is tolerant to a wide range of metals (1). Whole-genome transcriptomics demonstrated a common response in this organism for metal and oxidative stress (2). Some of the highly induced genes are well conserved within 14 *C. metallidurans* strains (3) and encode short proteins (coined the COPQ family) that possess a distinctive signal peptide and up to ten repetitive motifs [GSRD]XXD[PV][YF]T[DE]G[ASG].

**Objectives**

Bioinformatic analysis of the COPQ family.

**Methods**

Transcriptomic procedures are in (2). Structural predictions were performed with I-TASSER and PHYRE-2. Sequence similarity analysis was done by iterative BLAST against the non-redundant protein sequence database (nrdb – version 2014/09/10). Motif detection was done using BioGrep against 2,616 bacterial proteomes (refpep – version 2014/01/09).

**Conclusions**

BLAST analyses and BioGrep motif searches against reference protein databases showed that the CopQ family of proteins is strictly confined to the highly related species of *Cupriavidus* and *Ralstonia*. COPQ proteins are predicted to form straight, slightly helical polypeptides, probably owing to the abundance of chain-disturbing and evenly spaced glycines and prolines. The aromatic rings of the Tyr and Phe residues at the center of the motifs are fully exposed allowing easy access to reactive oxygen species (ROS).

We propose that COPQ-family proteins have a radical-scavenging function shielding cells from oxidative attack and/or metal toxicity. Highly purified COPQ proteins in single or mixed fashion are to be tested for their anti-oxidant and metal-binding

properties.

**BIODEGRADATION OF AROMATIC HYDROCARBONS BY HALOPHILIC  
ARCHEAE ISOLATED FROM ALGERIAN SEBKHAS**

S. KHEMILI-TALBI<sup>1</sup>, S. KEBBOUCHE-GANA<sup>1</sup>, S. AKMOUSSI-TOUMI<sup>1</sup>

<sup>1</sup>Biology-VALCOR, UMBB, Algiers, Algeria

**Background**

Actually, the biodegradation of hydrocarbons (specialy PAHs) has recieved great attention, however, such high and fluctuating salinity promotes the loss of cell wall integrity, protein denaturalization, and changes in osmotic pressure, the biological treatment of industrial hypersaline waste-waters and the bioremediation of polluted hypersaline environments are not possible with conventional microorganisms.

**Objectives**

The aim of our study is the identification of microorganisms that could answer these criteria for the biodegradation of extreme environments.

**Methods**

Three strains halophilic archaea *Haloarcula* sp.D21(AM982816), *Halovivax* sp.A21(AM982815) and *Natrialba* sp.C21(HG423210) were isolated from the salt lake close to Ain Salah, Algeria. These strains show good growth on extreme saline culture media (up to 25%NaCl) in the presence of diesel, naphthalene and pyrene as the sole carbon source. The strain *Natrialba* sp.C21 has a better growth on these media even at 35% of salt. However, the highest rate of biodegradation of these three hydrocarbons is labeled in the presence of extreme halophilic consortium containing the three strains. This biodegradation is marked by the high rate of growth of the strains measured by the optical density, the production of biosurfactans estimated by the emulsifying index and by the lowering of the surface tension of the culture media (below 40mN/m). In addition, the biodegradation of these hydrocarbons in the presence of the halophilic consortium is correlated with the rate of the concentration of NaCl and Mg<sup>2+</sup> in the medium.

**Conclusions**

Thus, our halophilic haloarchae strains, specialy *Natrialba* sp.C21, are potential candidates for the degradation of pollutants at high salt concentrations.

<sup>4</sup>Applied Sciences, Northumbria University, Newcastle, United Kingdom

<sup>5</sup>Human and Environmental Toxicology, University of Konstanz, Konstanz, Germany

<sup>6</sup>CIP, University of Liege, Liege, Belgium

### **Background**

Cyanobacteria produce a large variety of toxic secondary metabolites. In the Arctic and Antarctic, many unusual variants of microcystins (MCs) -the most common type of cyanobacterial freshwater toxins- have been detected. These variants are generally difficult to detect by standard methods in background-rich samples.

### **Objectives**

Therefore, there is a need to develop a screening method that can be used for a large number of environmental samples.

### **Methods**

In this study, 25 cyanobacterial samples from diverse biotopes in Svalbard (Arctic) were analyzed for the presence of MC. In a preliminary ADDA-MC specific ELISA, 18 of 20 samples were tested positive, an unusually high percentage. In contrast, a liquid chromatography-tandem mass spectrometry (LC-MS/MS) precursor-screening, newly designed to identify candidate MCs from the ADDA fragment ions, suggested the presence of MCs in nine of the 25 samples. In three of the latter, MC variants could be subsequently confirmed and identified by complete MS/MS analysis as variants of MC-RR and MC-LA, similar to those previously reported for polar habitats. In five of the same nine samples, a gene involved in toxin production -*mcyE*- was successfully amplified, validating the analytical data. The amplified gene sequences were 93-98% similar to *mcyE* genes of *Nostoc*, indicating that this genus could be responsible for MC production in these samples.

### **Conclusions**

The presence of the unusual variants in the polar regions could help to understand the evolution and ecological function of the toxins. Moreover, the toxicological risk of unusual toxins is not yet known and might be an undetected threat.

#### **'EX-SITU' PRESERVATION AND CHARACTERIZATION OF ANTARCTIC CYANOBACTERIA IN THE BCCM/ULC COLLECTION**

J. Kleinteich<sup>1</sup>, M. Renard<sup>1</sup>, C. Crahay<sup>1</sup>, V. Simons<sup>2</sup>, Y. Lara<sup>1</sup>, K. Waleron<sup>3</sup>,  
M. Waleron<sup>3</sup>, A. Wilmotte<sup>1</sup>

<sup>1</sup>CIP, University of Liege, LIEGE, Belgium

<sup>2</sup>BCCM, University of Liege, LIEGE, Belgium

<sup>3</sup>Department of Biotechnology, University of Gdansk, Gdansk, Poland

#### **Background**

The BCCM/ULC public collection of (sub)polar cyanobacteria is funded since 2011 by the Belgian Science Policy Office. An ISO9001 certificate was obtained for the public deposition and distribution of strains, as part of the multi-site certification for the BCCM consortium. BCCM/ULC is currently holding 160 public cyanobacterial strains and the catalogue is available on <http://bccm.belspo.be/catalogues/ulc-catalogue-search>.

#### **Objectives**

Continuous maintenance of living cultures, some of which are also cryopreserved, ensure the preservation and the possibility to rapidly deliver strains to clients for fundamental and applied research.

#### **Methods**

The main holding of the collection concerns (sub)polar strains isolated from different biotopes and representative of a large taxonomic diversity. The molecular characterization is underway, on the basis of 16S rRNA and ITS sequences, but also Multiple Locus Sequence Analysis and genome sequencing.

In addition, cyanobacteria are known to produce a range of secondary metabolites (e.g. alkaloids, cyclic and linear peptides, polyketides) with various bioactivities. The potential of the polar strains to produce cyanotoxins and other secondary metabolites is currently studied by ELISA, LC-MS and the detection of genes involved in their production.

#### **Conclusions**

Due to the geographic isolation and the strong environmental stressors of the habitat, the exploration of these metabolites in Antarctic cyanobacterial strains seems especially promising for biotechnology or biomedical applications.

**THE CRENARCHAEON *IGNICOCCUS HOSPITALIS* IS A POLYEXTREMOPHILIC ORGANISM WITH UNUSUAL HIGH RADIATION TOLERANCE**

D. Koschnitzki<sup>1</sup>, K. Beblo-Vranesevic<sup>1</sup>, H. Huber<sup>2</sup>, R. Rachel<sup>3</sup>, R. Wirth<sup>2</sup>, G. Reitz<sup>1</sup>, P. Rettberg<sup>1</sup>

<sup>1</sup>Department of Radiation Biology,  
Institute of Aerospace Medicine (German Aerospace Center (DLR)), Cologne,  
Germany

<sup>2</sup>Institute for Microbiology and Archaea Center,  
Faculty of Biology and Preclinical Medicine (University Regensburg), Regensburg,  
Germany

<sup>3</sup>Centre for Electron Microscopy,  
Faculty of Biology and Preclinical Medicine (University Regensburg), Regensburg,  
Germany

**Background**

The hyperthermophilic crenarchaeon *Ignicoccus hospitalis* was isolated from deep-sea hydrothermal vents living there strictly anaerobic and chemolithoautotrophic. From an astrobiological point of view, hyperthermophilic organisms are promising candidates for early Earth inhabitants, when the absence of oxygen, occasional meteorite impacts followed by heated up oceans, and the missing UV-absorbing ozone layer enabled higher radiation dose of short wavelength to penetrate Earth's surface.

**Objectives**

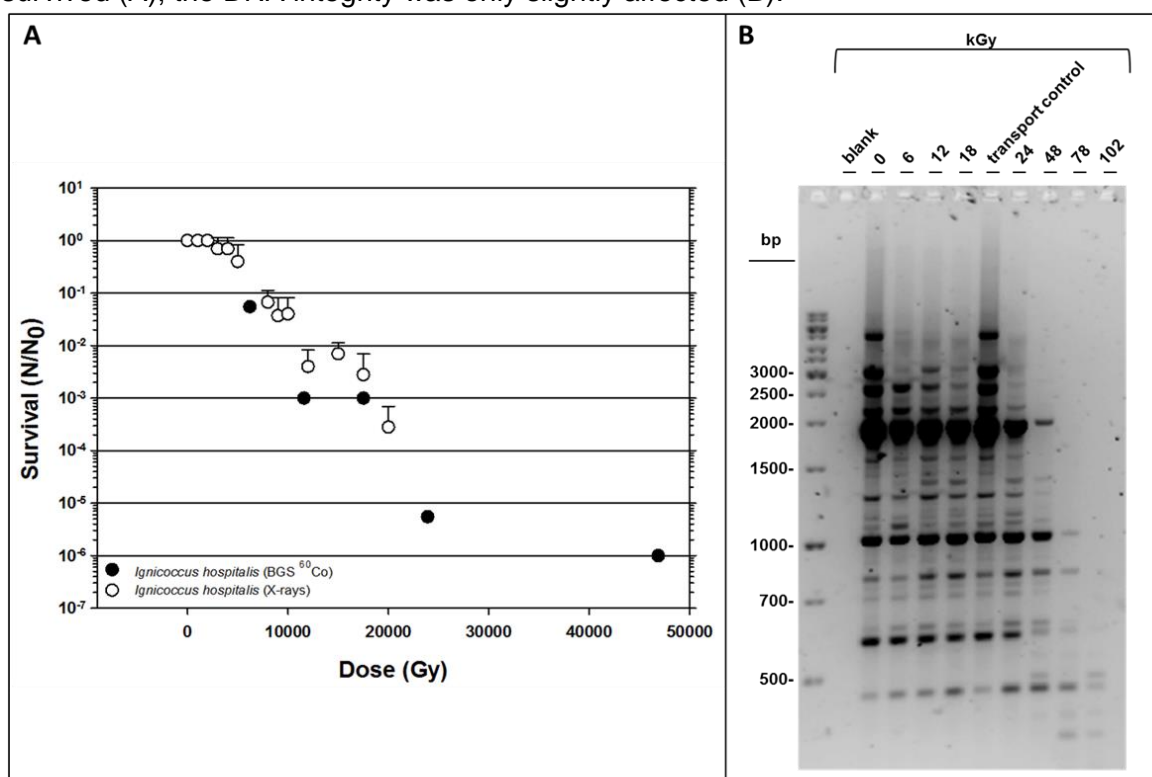

To ensure DNA integrity, *I. hospitalis* needs proper DNA repair mechanisms to cope with today's harsh environmental conditions in its natural habitat. These highly efficient DNA repair mechanisms might result in a tolerance to other yet untested harmful environmental impacts of astrobiological relevance. Therefore, *I. hospitalis*' radiation tolerance regarding ionizing and non-ionizing radiation has extensively been studied, and the DNA damage visualized on a molecular level. Future experiments will focus on repair kinetics and on the identification of proteins involved in DNA repair.

**Methods**

The survival after radiation exposure was determined by the most probable number technique (A), and PCR-based assays like RAPD (randomly amplified polymorphic DNA) analysis qualitatively confirmed changes in the genomic DNA after irradiation treatment (B).

## Conclusions

*I. hospitalis* cells showed a remarkable radiation tolerance although never exposed to it in its natural habitat. An exposure to 1000 J/m<sup>2</sup> monochromatic UV-C (254 nm) resulted in a reduction by 2-3 orders of magnitude which is in the same order as shown by *Deinococcus radiodurans*. An exposure to 24 kGy of ionizing radiation was survived (A); the DNA integrity was only slightly affected (B).

**A** Survival of *Ignicoccus hospitalis* after exposure to ionizing radiation. Cells were exposed to either  $\gamma$ -rays or X-rays. **B** RAPD profiles of genomic *I. hospitalis* DNA after ionizing radiation exposure.

<sup>4</sup>School of Arts and Sciences, St. George's University, St. Georges, Grenada

**Background**

*Ferroplasma acidarmanus* dominated the acid mine draining biofilm community in accordance with metagenomic metabolic modelling (Chen et al., 2012). One of the most impressive features of *F. acidarmanus* was its ability to survive at such an extreme proton gradient with only a cell membrane. The S-layer protects the cell against mechanical and osmotic stresses of extreme pH conditions. A rigid cell walls or S-layer were not documented neither in *F. acidarmanus* Fer1 nor *T. volcanium* as yet.

**Objectives**

Here we present an evidence for function of a gene coding for S-layer and the cellular localization of the protein in *F. acidarmanus* Fer1,

**Methods**

utilizing comparative tools including SignalP, TMHMM, SOSUI, Psort-B, Phobius, BLASTp, CDD, Pfam, Tigrfam, PDB, INTERPROSCAN, PrositeKEGG and Phylogeny.

**Conclusions**

The gene 638394352 was identified at 66-1422 (+) and coded for 452 amino acids with an isoelectric point of 10.08. The S-layer protein possessed a high content of acidic and hydrophobic amino acids. Protein played a structural role for the cell envelope and its biogenesis. We predicted two transmembrane domains of about 20 aa each anchored within the membrane while the majority of amino acids were located extracellular. The gene shared sequence homology with S-layer domain protein from *Sulfolobus islandicus*. The cellular localization model of 638394352 agreed with the cellular structure and localization of S-layer protein of orthologues *Sulfolobus*, which formed extracellular monomolecular crystalline mushroom-like

arrays of proteinaceous subunits on the cellular surface.

Figure 4. Model of cellular localization of protein product of OID 638394352 from *F. acidarmanus* fer 1 produced based on combined results of SOSUI, Phobius, SignalP, TMHMM and PSORT.

The peptide statistics, cellular localization, and protein homology, indicated that the gene was coding for S-layer domain..

## **THERMAL ADAPTATION OF ESTERASES THROUGH THE EVOLUTION OF LOOP REGIONS**

F. Kovacic<sup>1</sup>, A. Mandrysch<sup>1</sup>, C. Poojar<sup>2</sup>, B. Strodel<sup>1</sup>, K.E. Jaeger<sup>1</sup>

<sup>1</sup>Heinrich-Heine-University Düsseldorf, Institute of Molecular Enzyme Technology, Juelich, Germany

<sup>2</sup>Forschungszentrum Juelich GmbH, Institute of Complex Systems ICS-6: Structural Biochemistry, Juelich, Germany

### **Background**

Temperature exerts multiple effects on the structure and function of enzymes which are still poorly understood at the molecular level. The adaptation of microorganisms to extreme temperatures includes the evolutionary development of biocatalysts with a high catalytic efficiency under these conditions. Nowadays, such extremophilic enzymes are used as valuable tools to study relationships between protein stability, dynamics, and function.

### **Objectives**

Here, we report on a comparative biochemical and molecular dynamics analysis of four homologous esterases belonging to the hormone sensitive lipase family which were isolated from bacteria living at temperatures ranging from 10°C to 70°C.

### **Methods**

The recombinant esterases showed highly similar substrate specificities. Furthermore, their optimal temperatures and thermostabilities resembled the temperatures of the respective bacterial habitats. Apparently, the thermal properties of these esterases were optimized to sustain the temperatures of their respective habitats. Therefore, we have used this set of enzymes for the analysis of molecular determinants beyond thermal adaptation.

### **Conclusions**

The structural analysis revealed significant differences between structures arising from surface exposed loop regions. The high flexibility of these structural domains was confirmed by molecular dynamics simulations performed at temperatures ranging from 15°C to 90°C. The results led us to propose four highly flexible loops (L2, L4, L10 and L12) distant from the active site as the structural regions most relevant for thermal stability. The link of such surface exposed loop-structures to thermal stability may indicate that natural thermal adaptation is achieved by tuning atomic interactions in “non-active site” loops without interfering with the catalytic function of an enzyme.

<sup>6</sup>*Programa de Biología Celular y Molecular, Universidad de Chile, Santiago, Chile*

**Background**

Acid bioleaching environments are characterized by high levels of iron and heavy metals, which can increase the generation of reactive oxygen species and induce oxidative stress in microorganisms. Metaproteomic studies on *Leptospirillum* spp., a member of the bioleaching consortium, have shown that it contains high levels of cobalamin biosynthesis proteins. We have found that cobalamin exerts an antioxidant effect in *Leptospirillum* group II strains.

**Objectives**

The aim of this study was to clarify the possible mechanisms involved in cobalamin effect in *Leptospirillum* group II strain CF-1 through transcriptomic and proteomic approaches.

**Methods**

The sequencing and annotation of the genome were carried out using PacBio RS II technology and RAST software, respectively. Transcriptomic profile was obtained by RNA-seq using Illumina HiSeq 2500 sequencing. The mRNA abundance was calculated using Blast and expressed as RPKM (reads per kilobase per million) data. Proteomic assays were carried out using 1D-PAGE LC-MS/MS, and the LFQ intensities were normalized by MaxQuant software.

**Conclusions**

The genome analysis showed one circular chromosome with 2,709,324 bp and 3,070 coding sequences. Transcriptomic and proteomic analyses showed that cobalamin produces up-regulation of pathways involved in biosynthesis and repair of proteins, biosynthesis of iron sulfur clusters and amino acids, biofilm formation and energy metabolism proteins. Most of up-regulated pathways use S-adenosylmethionine or folate as cofactors which are products of cobalamin-dependent methionine and folate cycles. These data lead us to suggest that cobalamin could activate the central metabolism, improving the response to oxidative damage and restoring redox balance of the cell.

**THE FE-S CLUSTER ASSEMBLY (ISC) SYSTEM IS FUNCTIONAL UNDER  
OXIDATIVE STRESS AND IRON STARVATION CONDITIONS IN THE  
ACIDOPHILIC BIOLEACHING BACTERIUM LEPTOSPIRILLUM GROUP II CF1**

G. Levican<sup>1</sup>, B. Paillavi<sup>2</sup>, R. Quatrin<sup>2</sup>

<sup>1</sup>Facultad de Química y Biología, Universidad de Santiago de Chile, Santiago, Chile

<sup>2</sup>Facultad de Química y Biología, Universidad de Santiago de Chile, Santiago, Chile

**Background**

The synthesis and assembly of Fe-S clusters is a highly complex and coordinated process in living cells. The ISC system is the housekeeping [Fe-S] cluster assembly system whereas the SUF system is functional under harsh environmental conditions such as oxidative stress and iron starvation. Members of *Leptospirillum* genus are acidophilic iron-oxidizing bacteria that belong to the consortium of microorganisms that participate in the bioleaching of ores and metal recovery. Interesting, despite to inhabit in a highly oxidizing environment with high concentrations of metals, these microorganisms have only one [Fe-S] cluster assembly system, ISC

**Objectives**

In this work we evaluated the functionality of the [Fe-S] cluster biogenesis system ISC of *Leptospirillum* Group II CF-1.

**Methods**

Bioinformatic analysis and RT-PCR experiments were used to characterize the genetic clusters that contain *isc* genes and to evaluate the co-transcription of genes. The expression level of key genes *iscR*, *iscS* and *hscB* was determined by quantitative RT-PCR analysis when cells were exposed to oxidative stress and iron starvation. The functionality of the ISC system was evaluated measuring the activity of cysteine desulfurase enzyme (IscS).

**Conclusions**

The results showed that *Leptospirillum* Group II CF-1 responds to oxidative stress and iron starvation by up-regulating the [Fe-S] cluster assembly *isc* genes and increasing the activity of IscS.

<sup>2</sup>BR2 Reactor Operational Management, SCKCEN, Mol, Belgium

<sup>3</sup>Research Group Astrobiology, DLR, Köln, Germany

<sup>4</sup>Proteomics and Microbiology Group, UMons, Mons, Belgium

### **Background**

The cyanobacterium *Arthrospira* sp. PCC 8005 has been selected by the European Space Agency (ESA) for producing oxygen and food during future long-duration manned space missions, as part of the bio-regenerative life support system 'MELiSSA'. PCC 8005 must continue to produce oxygen and conserves high nutritive value while exposed to cosmic radiation in space.

### **Objectives**

The tolerance and the response of *Arthrospira* sp. PCC 8005 to ionizing radiation were investigated.

### **Methods**

Metabolically active planktonic cells of were exposed to Cobalt-60-generated gamma radiation and Helium and Iron particle radiation. The molecular response to radiation was investigated via photosynthesis, pigment, antioxidant, proteome and transcriptome analysis.

### **Conclusions**

The cells of PCC 8005 were able to survive doses of 6400 Gy of gamma, and 1000 and 2000 Gy of He and Fe particle radiation. During irradiation, cells switched quickly from an active growth state to a growth arrest mode, via a shut-down of photosynthesis and carbon fixation. Resources were rerouted to cellular protection and repair. Various antioxidant systems were activated, such as glutathione, to protect lipids, proteins and DNA. The cells activated also ssDNA repair systems and systems to remove damaged amino and nucleic acids from the cells. During recovery, the cells induced the *arh* genes, a new cluster of genes with unknown function. Finally, energy and metabolic pathways were restarted, and full recover of photosynthetic proliferation was obtained. These results show that *Arthrospira* sp.

PCC 8005 is a peculiar radiation resistant bacterium, useful for biotechnological applications, in space and on Earth.

<sup>5</sup>Universidad de Concepción, Departamento de Oceanografía, Concepción, Chile

<sup>6</sup>Universidad de Valparaíso, Centro de Investigación y Gestión de Recursos Naturales, Valparaíso, Chile

**Background**

Carbon dioxide (CO<sub>2</sub>), methane (CH<sub>4</sub>) and nitrous oxide (N<sub>2</sub>O) are three major greenhouse gases (GHG) which are naturally recycled mainly by microbiological mechanisms including respiration- CO<sub>2</sub> fixation, nitrification -denitrification and methanogenesis-methanotrophy. Microbial groups involved in GHG recycling have been detected through molecular surveys in high altitude wetlands such as Salar de Huasco. This site is a high altitude wetland characterized by its extreme physical-chemical environmental conditions (high radiation, daily temperature shifts, salinity gradients) and by the presence of novel groups within Bacteria and Archaea domains and complex microbial structures (mats) in freshwater and salt-saturated sites.

**Objectives**

The aim of this study was to determine atmospheric and dissolved GHG concentration in Salar de Huasco wetland and dry Altiplanic adjacent areas (3,800 - 4,000 masl) and the potential communities involved in its recycling during the austral dry season (November 2014).

**Methods**

GHG were measured in discrete samples from air, water and gas bubbles below microbial mats inhabiting fresh water areas of Salar de Huasco wetland by standard chromatography. Also molecular analyses of the communities were studied using massive sequencing (metagenomic and 16S rRNA barcode).

**Conclusions**

This study indicates that Salar de Huasco microbial communities process GHG very fast since despite notorious accumulation of CH<sub>4</sub> bubbles (over N<sub>2</sub>O) in cyanobacterial-microbial mats from fresh-water areas were found, the wetland was a net sink of GHG based on undersaturated values in the water and low ground air GHG levels compared with dry adjacent areas.

## **HALOPHILIC FILAMENTOUS FUNGI FROM HYPERSALINE AND POLYHALINE ENVIRONMENTS**

S. Nazareth<sup>1</sup>, V. Gonsalves<sup>1</sup>

<sup>1</sup>*Microbiology, GOA UNIVERSITY, Panjim, India*

### **Background**

The existence of halophilic fungi in hypersaline environments has now been well established, negating the former belief that their presence was as simply ubiquitous fungi, or as being merely halotolerant. Several reports have indeed demonstrated the presence of these fungi in the Dead Sea and in solar salterns.

### **Objectives**

Although hypersaline environments have been recorded as the primary econiche of halophilic fungi, the objective herein, was to ascertain the presence of this extremophilic group of fungi in polyhaline environments of the estuary and mangroves, in addition to solar salterns, and to characterise their nature of halophily.

### **Methods**

Samples of water and sediment were obtained from these econiches and plated on to medium supplemented with high concentration of solar salt. The purified isolates so obtained were screened for their halotolerance levels, by growth on media containing increasing concentrations of salt.

### **Conclusions**

Halophilic fungi were indeed isolated from polyhaline environments, as well as from hypersaline solar salterns. Most of the halophilic fungi screened were found to possess moderate halophily; some of the isolates were true halophiles, having an essential requirement of salt for growth. It is thus shown that this group of extremophilic fungi may be found in hypersaline as well as non-hypersaline marine environments.

**DEVELOPMENT OF BIOLOGICAL SOIL CRUST ON THE BARE SOIL MOUNDS AFTER SHRUB DEATH AND DECOMPOSITION IN A SEMI-ARID ECOSYSTEM**

A. Nejdat<sup>1</sup>, F. Garcia-Pichel<sup>2</sup>, R.M. Potrafka<sup>2</sup>, E. Zaady<sup>3</sup>

<sup>1</sup>*Environmental Hydrology and Microbiology, Ben-Gurion University of the Negev, Sede Boqer, Israel*

<sup>2</sup>*School of Life Sciences, Arizona State University, Tempe, USA*

<sup>3</sup>*Department of Natural Resources, Agriculture Research Organization, Gilat, Israel*

**Background**

**Background:** By the end of 2008, and following a prolonged drought period, a mass death of shrubs was observed in a semi-arid region of the Northern Negev Desert.

**Objectives**

**Objective:** This study followed the development of biological soil crusts (BSCs) on the soil mounds in the sites of the dead shrubs, spanning over a three year period, from the disappearance of the shrub skeletons until the mounds were flattened.

**Methods**

**Methods:** In addition to on-site physical measurements, BSC samples were collected and analyzed for their physical and biochemical properties (15-17 parameters) and their microbial community structure and compared to those of mature crusts.

**Conclusions**

**Conclusions:** Statistical analyses showed significant differences in the biochemical properties and the microbial community structure between the developing BSCs and the mature ones during five sampling campaigns. Interestingly, significant differences were observed also between the north-facing and the south-facing slopes of the mounds. The extent of these observed differences was linked to the sampling dates, implying an effect of the soil moisture. Significant differences persisted even after the mounds were totally flattened. This slow development of BSCs on the bare soil mounds after shrub death and decomposition in semi-arid ecosystems, may allow the establishment of new shrubs in these sites and the recovery of the affected ecosystem.

#### GDGT LIPID COMPOSITION OF THE THERMOPHILIC ARCHAEA

A.A. Perevalova<sup>1</sup>, D.S. Kopitsyn<sup>2</sup>, D.A. Beskorovaynaya<sup>2</sup>, M.S. Kotelev<sup>2</sup>, A. Novikov<sup>2</sup>

<sup>1</sup>Laboratory of hyperthermophilic microbial communities,  
Wlnogradsky Institute of Microbiology RAS, Moscow, Russia

<sup>2</sup>Physical and Colloid Chemistry, Gubkin Russian State University of Oil and Gas,  
Moscow, Russia

#### Background

The archaeal lipids differ significantly from the bacterial and eukaryotic analogs. The most studied lipids of thermophilic archaea are ether-bonded glycerides, resistant to usual lipid derivatization methods. Thus, characterization of archaeal lipid profiles is often not provided with the description of novel species.

#### Objectives

In our work, we have analyzed the composition of polar lipids, cellular fatty acids and the GDGT lipids of the several thermophilic archaea (*Thermoplasma* sp. DSM-1728<sup>T</sup>, *Desulfurococcus* sp. Z-1312<sup>T</sup>, and *Fervidicoccus* sp. Kam-940<sup>T</sup>), among them are several recently described species.

#### Methods

Polar lipids were studied by two-dimensional thin-layer chromatography [1,2], GDGT lipids were analyzed by GC-MS after iodination with subsequent reduction by Zn/CH<sub>3</sub>COOH [3]. Additionally, native GDGT lipids were analyzed by ESI-MS, and the polar groups of GDGT lipids were silylated and analyzed by GC-MS.

#### Conclusions

The polar groups of GDGT lipids of DSM-1728<sup>T</sup> contained phosphate, mannose, arabinose and gulose. This is confirmed by glycolipids and glycopospholipids revealed by TLC.

The GDGT lipids of *Thermoplasma acidophilum* DSM-1728<sup>T</sup> are dominated by GDGT4, which is confirmed by GC-MS analysis of core hydrocarbons. The polar lipid profiles of archaea studied are strikingly different, however, there are common glycopospholipids for the DSM-1728<sup>T</sup>, Z-1312<sup>T</sup>, and Kam-940<sup>T</sup> strains. The further study of lipids of these archaea by LC-MS will clarify their structures.

This work is supported by Russian Foundation for Basic Research (grant #13-04-40328) and by President of Russia (grant MK-4530.2015.4).

**USING A FUNCTION-BASED SCREEN TO IDENTIFY ACTIVE RUBISCOS FROM HYDROTHERMAL VENT ENVIRONMENTS: UNRAVELING REGULATION AND ACTIVATION OF A RUBISCO ENCODED ON A METAGENOMIC FRAGMENT**

M. Perner<sup>1</sup>, S. Böhnke<sup>1</sup>

<sup>1</sup>*Microbiology, University of Hamburg, Hamburg, Germany*

**Background**

RubisCO (Ribulose-1.5-bisphosphate Carboxylase/Oxygenase) is a key enzyme in the Calvin Benson Bassham cycle, which accounts for most of Earth's primary production. Although extensive work on RubisCO enzymes has been conducted in the last decades, we still know relatively little about the regulation and activation of RubisCO enzymes.

**Objectives**

We have developed a new activity-based screen that enables the identification of recombinant RubisCO active enzymes from metagenomic fosmid libraries. Using this screen we successfully harvested RubisCOs from a metagenomic fosmid library that was constructed from a deep-sea hydrothermal vent. After verifying the RubisCO activity, sequencing of one of the metagenomic fragments revealed a 35 kb DNA insert which encoded a RubisCO form I and form II.

**Methods**

We investigated the role of adjacent DNA regions on the RubisCO form I and form II regulation and activation by individually deleting each of the flanking genes and measuring the mutant's activity. Additional experiments with the genes' transcripts and band shift assays, to assess binding properties of the respective enzymes and genes, have furthered our understanding of how the RubisCO is regulated and likely activated.

**Conclusions**

This screen and this approach to work with the metagenomic fragments opens the door to directly studying RubisCOs from any environmental sample.

**UV-RESISTANCE PROFILING OF A POLY-EXTREMOPHILIC  
GAMMAPROTEOBACTERIUM FROM HIGH-ALTITUDE ANDEAN LAKES**

L. PORTERO<sup>1</sup>, F. Zannier<sup>1</sup>, D. Kurth<sup>1</sup>, M. Gorriti<sup>1</sup>, O. Ordoñez<sup>1</sup>, C. Belfiore<sup>1</sup>,  
M. Farias<sup>1</sup>, V. Albarracín<sup>1</sup>

<sup>1</sup>LIMLA, Planta Piloto de Procesos Industriales Microbiologicos (PROIMI),  
San Miguel de Tucuman, Argentina

**Background**

High-Altitude Andean Lakes (HAAL) at the South American Andes are exposed to high UV irradiation and high content of toxic elements. A wide variety of microorganisms named “extremophiles” were found to inhabit these environments as *Acinetobacter* sp. Ver3<sup>1</sup> and it was chosen as model poly-extremophilic HAAL’s microbe as it displayed high resistance to UV-B.

**Objectives**

The aim of this work is to integrate diverse experimental approaches to profile the UV resistance mechanisms of Ver3, herein called as “UV-resistome”.

**Methods**

DSMZ collection strains were used for comparison with Ver3. Strains were exposed to different doses of UV-B, the resistance was determined by colony forming unit counting<sup>2</sup>. Survival, proteomic profiling and biofilm development after the exposure was evaluated by incubating cells under dark (DR) or light (PR) treatments. Genomic data were analyzed identifying components related with the “UV-resistome”.

**Conclusions**

Our results shown a superior resistance to UV-B radiation of Ver3 than control strains, in all cases the recovery was more efficient after PR, and the genome sequence supported the phenomenological observations. Ver3 highlighted a number of unique genes, such as a novel cryptochrome. An “UV-resistome” was defined, mainly genes related to UV-damage repair<sup>3,4,5</sup> on DNA and genes conferring an enhanced capacity for scavenging the reactive molecular species responsible for oxidative damage. The proteomic profiling of UV-challenged cells identified up-regulated proteins such as a specific cytoplasmic catalase, a putative regulator of quorum sensing, biofilm development and down-regulated proteins related to several energy-generating pathways. This is the first report on a genome from a polyextremophilic *Acinetobacter* strain.

## **BACTERIAL DIVERSITY OF GEOTHERMAL SPRINGS IN NAGORNO-KARABAKH**

A. Saghatelyan<sup>1</sup>, H. Panosyan<sup>1</sup>, A. Trchounian<sup>1</sup>, N.K. Birkeland<sup>2</sup>

<sup>1</sup>*Microbiology Plant and Microbe Biotechnology, Yerevan State University, Yerevan, Armenia*

<sup>2</sup>*Department of Biology and Centre for Geobiology, University of Bergen, Bergen, Norway*

### **Background**

The ability of microbes to thrive in high-temperature environments has prompted researchers to study these microorganisms to better understand their physiological and molecular adaptations and eventual utilization in various biotechnological applications. Natural geothermal springs, including terrestrial hot springs are one of the habitats of thermophilic microbes. On the territory of Nagorno-Karabakh many geothermal springs with different geotectonic origins and different physicochemical properties are found.

### **Objectives**

This research is focused on investigation of the bacterial community structure of previously unexplored geothermal springs of Nagorno-Karabakh, Karvachar (70°C) and Zuar (52°C).

### **Methods**

16S rRNA gene clone libraries were constructed from total community DNA using universal bacterial oligonucleotide primer sets. Sequences were used for phylogenetic assessment of the communities.

### **Conclusions**

Sequence analysis of clones indicated that clones obtained from Karvachar samples originated from phyla *Proteobacteria* (48.6%), *Cyanobacteria* (29.7%), *Bacteroidetes* (5.4%), *Chloroflexi* (5.4%), *Verrumicrobia* (2.7%) and *Planctomycetes* (2.7%) and clones obtained from Zuar samples originated from phyla *Proteobacteria* (42.3%), *Firmicutes* (19.2%), *Bacteroidetes* (15.4%), *Cyanobacteria* (3.8%), *Tenericutes* (3.8%) and yet unclassified phylotypes (15.4% for Zuar and 3% for Karvachar). The majority of the phylotypes detected in the gene libraries shared less than 95% sequence identity with their closest matches in GenBank, indicating a unique community structure of these geothermal springs. These thermal springs can represent a resource for novel thermophilic organisms and biotechnological tools.

The work was supported by the CPEA-2011/10081 grant from the Norwegian Cooperation Programme in Higher Education with Eurasia.

#### **LIFE ON THE FROZEN CONTINENT: DIVERSITY OF RUBISCO, NIFH AND PUF<sub>LM</sub> GENES IN SOILS AROUND THE PRINCESS ELISABETH STATION, SØR RONDANE MOUNTAINS, ANTARCTICA.**

G. Tahon<sup>1</sup>, B. Tytgat<sup>1</sup>, P. Stragier<sup>1</sup>, A. Willems<sup>1</sup>

<sup>1</sup>Biochemistry & Microbiology - Laboratory of Microbiology, Ghent University, Ghent, Belgium

#### **Background**

In Antarctica, photosynthesis by Cyanobacteria is generally thought to be the main primary source of organic carbon for complex microbial communities. Many cyanobacterial species are also able to fix nitrogen. Therefore, they can survive and prosper in almost every habitat, including Antarctica, Earth's most extreme continent. However, several studies of Antarctic microbial communities have shown that Cyanobacteria are not always highly abundant. We explored the hypothesis that other bacteria must take over their role and produce organic matter as well as fix nitrogen, in order to sustain the microbial community. Light is an abundant energy source during the Antarctic summer and some bacteria can use rhodopsin-type pigments to exploit this, whereas aerobic anoxygenic photosynthetic bacteria can use bacteriochlorophyll for photosynthesis.

#### **Objectives**

The presence and diversity of non-cyanobacterial prokaryotes that possess one or several of these properties was studied in terrestrial samples gathered in the proximity of the Belgian Princess Elisabeth Station (Sør Rondane Mountains, Queen Maud Land, East-Antarctica).

#### **Methods**

RuBisCO, *nifH* and *pufLM* genes were investigated by construction of PCR clone libraries and Illumina MiSeq sequencing.

#### **Conclusions**

Preliminary results indicate an extensive diversity of the genes coding for these processes in terrestrial Antarctica.

#### **SOIL PROTEOMICS AND ATOMIC FORCE MICROSCOPY OF WATER-REPELLENT SOILS, A NEWLY RECOGNISED 'EXTREME' ENVIRONMENT**

G. van Keulen<sup>1</sup>, G. Quinn<sup>1</sup>, S.A. Gazze<sup>1</sup>, I. Hallin<sup>2</sup>, K. Sinclair<sup>1</sup>, A.E. Bond<sup>1</sup>, E. Dudley<sup>1</sup>, L. Lewis<sup>1</sup>, S. Doerr<sup>3</sup>, G.P. Matthews<sup>2</sup>

<sup>1</sup>*Institute of Life Science - College of Medicine, Swansea University, Swansea, United Kingdom*

<sup>2</sup>*Earth and Environmental Sciences - School of Geography, Plymouth University, Plymouth, United Kingdom*

<sup>3</sup>*Geography Department - College of Science, Swansea University, Swansea, United Kingdom*

#### **Background**

Soil water repellency is a common phenomenon affecting the hydrological responses of many soil and land use types in different climates. This newly recognised 'extreme' environment leads to decreased water infiltration, reduced vegetation cover, fertiliser run off and soil erosion. The fundamental (biological) causes of soil repellency and its dynamic behaviour remain poorly understood.

#### **Objectives**

This study aimed to apply metaproteomic and high-resolution imaging approaches to model and predict switches between hydrophilic and hydrophobic soil surface responses.

#### **Methods**

Extreme, moderate and sub-critical water-repellent UK grassland soils, including Park Grass at Rothamsted Research, were sampled under wettable and repellent conditions. Soils were subjected to new extraction methods for determining the specific hydrophobic and the general metaproteomes and to Atomic Force Microscopy for determination of topological and adhesion properties.

#### **Conclusions**

Using our ultrahydrophobic extraction protocol, we identified novel ultra-hydrophobic microbial proteins, which likely play an important role in the development of soil water repellency. Such proteins could be extracted from moderate and extremely hydrophobic soils with medium-low soil moisture levels, but were absent in the comparable wettable soils. In control extractions, hydrophobic proteins were only extracted from wettable soil containing a positive control, demonstrating the specificity of our novel extraction method. Our newly developed metaproteomic method required only up to 0.5g of soil. Initial comparisons revealed differences in protein profiles, suggesting altered microbial ecophysiology in response to development of water repellency. Atomic force microscopy of repellent soils showed the nanoscale coverage of repellency on particles and aggregates by determining surface adhesion properties from force curves.

**SPIRIBACTER SALINUS, A HALOPHILIC BACTERIUM DOMINANT ON  
HYPERHALINE HABITATS**

M.J. Leon<sup>1</sup>, T. Hoffman<sup>2</sup>, N. Widderich<sup>2</sup>, C. Sanchez-Porro<sup>1</sup>, E. Bremer<sup>2</sup>, A. Ventosa<sup>1</sup>

<sup>1</sup>Dept Microbiology and Parasitology, University of Seville, Seville, Spain

<sup>2</sup>Dept of Biology, Philipps University Marburg, Marburg, Germany

**Background**

Metagenomic studies carried out in salterns located in Alicante and Huelva, Spain, revealed that in intermediate salinities ponds (13-21‰ of salts) inhabits a dominant bacterial group belonging to *Gammaproteobacteria*, related to *Alkalilimnicola*, *Arhodomonas* and *Nitrococcus*.

**Objectives**

On the basis of these metagenomic studies we designed different media and growth conditions in order to isolate this bacterium that have shown to be dominant at intermediate salinities. Subsequently, we studied the strategy of osmoregulation of this successful halophilic bacterium.

**Methods**

.

**Conclusions**

We were able to isolate a microbe that has been cultured and described as *Spiribacter salinus*. Its complete genome has been sequenced and the recruitments against the available metagenomes of hypersaline aquatic habitats revealed its abundance in intermediate salinities, decreasing sharply at saturated and low salinities. *S. salinus* shows a simplified metabolic versatility, missing the chemolithotrophic and carbon fixation pathways.

We have combined physiological approaches and genomic analysis to derive a comprehensive picture of the molecular and cellular events that allow the adaptation of *S. salinus* to saline environments. A qualitative and quantitative assessment by natural abundance <sup>13</sup>C-NMR spectroscopy and high-performance liquid chromatography (HPLC) analysis, respectively, have shown that *S. salinus* is able to synthesize ectoine when is exposed to high salinity, showing an essentially linear relationship between ectoine content of the cells and the external salinity. We have also tested representatives of multiple transporter families that have been proved to sense and respond to osmotic stress, from ABC transporter as OpuA, BCCT transporter as OpuD and from the TRAP- transporter family, TeaABC.

**MONITORING OF MICROBIAL CHANGES IN DRIPPING WATER OVER 5 YEARS  
IN HESHANG CAVE, HUBEI, CENTRAL CHINA**

*H. Wang<sup>1</sup>, Y. Yun<sup>1</sup>, X. Xiang<sup>1</sup>, B. Man<sup>1</sup>, J. Zhou<sup>1</sup>, R. Zhao<sup>1</sup>, Y. Duan<sup>1</sup>*

*<sup>1</sup>School of Environmental Studies, China University of Geosciences, wuhan, China*

**Background**

Heshang Cave is a dissolution cave occurred in Cambrian dolomite. It is characterized by dark, oligotrophic, well-developed stalagmite and continuous dripping water throughout the year.

**Objectives**

Due to the great progress on the geochemical record and successful recover of microbial geolipids from stalagmite, it poses an urgent need to investigate microbial changes in terms of their relationship with environmental conditions which will help to decipher the microbial information in stalagmite.

**Methods**

Here we present a five year monitoring results about the variation of microbial communities in dripping waters in Heshang cave via 16S rRNA clone library construction and Biolog analysis of their carbon utilization. Meanwhile pH, temperature, conductivity, dripping rate, regional air temperature and precipitation were measured and collected.

**Conclusions**

Seasonal variations of bacterial communities were observed in composition, diversity and carbon utilization patterns. In autumn and winter bacterial community was dominated by Gammaproteobacteria, whereas in summer and spring Betaproteobacteria became dominant in water samples collected. Cluster and redundancy analysis indicated that regional air temperature strongly affect bacterial communities among the environmental factors investigated. Moreover the bacterial biodiversity was observed to increase with the temperature rising. These seasonal variation match well with the seasonal variation of microbial fatty acids in dripping waters in Heshang Cave which was also strongly affected by regional temperature. Our results show that microbial communities can response temperature change via multiple ways and the microbial variation recorded in stalagmite may be indicative of palaeo-temperature changes.

## **VARIATIONS BETWEEN MICROBIAL COMMUNITIES IN DEEP SUBSURFACE BOOM CLAY PIEZOMETER INSTALLATIONS**

K. Wouters<sup>1</sup>, M. Mysara<sup>1,2</sup>, H. Moors<sup>1</sup>, N. Leys<sup>1</sup>

<sup>1</sup>*Environment Health and Safety - Microbiology,*

*Belgian Nuclear Research Center SCK•CEN, Mol, Belgium*

<sup>2</sup>*Department of Bioscience Engineering, Vrije Universiteit Brussel, Belgium*

### **Background**

The subsurface Boom Clay layer is investigated as a potential host rock for geological disposal of radioactive waste in Belgium. The HADES underground research facility (EIG Euridice c/o SCK•CEN), located at 230 m depth under the site of SCK•CEN (Mol, Belgium), provides access to this clay layer for *in situ* geological, geochemical and geomicrobiological testing.

### **Objectives**

In order to predict how microbiology will affect the biogeochemical processes in a disposal scenario, the resident microbial communities in the man-made structures within Boom Clay are being characterised.

### **Methods**

In this study, water samples were collected from Boom Clay via various existing piezometers (diverse in depth, orientation, location, age, materials used). The aim was to assess differences or shared features of the microbial communities residing in piezometer boreholes, and to correlate variations to geochemical analyses.

### **Conclusions**

Along the five piezometers, bacterial communities of the filters within one piezometer seem more similar to each other compared to those in other piezometers, despite a variety of filter materials or Boom Clay layers sampled within one piezometer. It shows that technical installations (such as piezometers) can introduce and promote local variations in the clay environment and the associated bioprocesses.

Further studies of other piezometers and of clay samples are needed, to pinpoint the source bacterial community underlying *in situ* enrichment, to unravel the mechanism that shapes such microbial community in different repository conditions and to outline the relevance of the (dominant) microbial classes in defining borehole water (and gas) chemistry.

<sup>6</sup>Laboratory of Human Bacterial Pathogenesis, US National Institutes of Health, Bethesda, USA

<sup>7</sup>Microbial Genetics, University of Tübingen, Tübingen, Germany

#### **Background**

*Staphylococcus aureus* (SA) is a Gram-positive bacterium responsible for a wide range of infections in humans and animals. We previously demonstrated that SA USA400 MW2 strain induces a G2/M phase delay in human HeLa cells. This phenomenon was associated with the accumulation of the cyclin-dependent kinase Cdk1/cdc2 and with the accumulation of unphosphorylated histone H3. Additionally we showed that the G2 phase was preferential for staphylococcal internalization and intracellular replication (1).

#### **Objectives**

The objectives of the study were

- to identify the active substances, which are responsible for the cell cycle alteration,
- to understand, how this alteration hijacks defense functions of the host cells.

#### **Methods**

Using size exclusion chromatography of MW2 supernatant, followed by mass spectroscopy analysis and FACS, we identified phenol-soluble modulin alpha (PSM $\alpha$ ) peptides as the likely candidates for cell cycle alteration.

#### **Conclusions**

Synthetic PSM $\alpha$ 1 and PSM $\alpha$ 3 caused a G2/M phase transition delay. The implication of PSM $\alpha$  in cell cycle alteration was confirmed by comparison of wild type LAC wt

strain with the isogenic mutant ( $LAC\Delta psma$ ), lacking the *psma* operon that encodes PSM $\alpha$ 1 to 4, for its internalization efficiency in HeLa cells. The decreased internalization rate of  $LAC\Delta psma$  suggested a role of PSM $\alpha$  in host cell invasion.

Furthermore, PSM $\alpha$ -induced G2/M-transition delay correlated with a decrease in the defensin genes expression suggesting a diminution of antibacterial functions of epithelial cells (2). Our results open new perspectives for the investigation of the mechanisms of the SA infection.

**LACTOBACILLUS ACIDOPHILUS1 MAY PREVENT DIARRHEAL DISEASE BY VIBRIO CHOLERAЕ IN NEWBORN RABBITS**

A. Pazos<sup>1</sup>, M. Guerrero<sup>1</sup>, J. Caguazango<sup>1</sup>

<sup>1</sup>Biology, University of Nariño, Pasto, Colombia

**Background**

Acute diarrheal disease-ADD is the second cause of death in the world in children under five years old and particularly in Latin America a good proportion is caused by *Vibrio cholerae*. The high incidence of ADD produced by *V. cholerae* is mainly due to antimicrobial resistance, being mainly to get control of cholera with probiotics our scientific interest.

**Objectives**

To assess the *in vitro* and *in vivo* capacity of *Lactobacillus acidophilus*1 to prevent diarrheal disease caused by *V. cholerae* 01OGAWA, in newborn rabbits. Our working hypothesis is to evaluate the use of lactic acid bacteria-LAB in the prevention and control of ADD.

**Methods**

Isolated and identified by biochemical and molecular tests *L. acidophilus*1, from 35 Colombian children stools. The amylolytic capacity and biomass formation by *L. acidophilus*1 were standardized previously. With *L. acidophilus*1, *in vitro* and *in vivo* antagonistic activities against the enteropathogen were performed and prevention of diarrheal disease was evaluated by *V. cholerae* in newborn rabbits.

**Conclusions**

The isolate was identified as *L. acidophilus*1, who in an inoculum of  $35 \times 10^6$  bacteria/ml was able to exert the most antagonistic *in vitro* effect on *V. cholerae*. After the *Kaplan–Meier* estimator, rabbits faced to the pathogen without receiving probiotic had lower survival probability of 0.25 compared to the group of animals challenged to the pathogen and simultaneously fed with probiotic whose probability of survival was 0.95. *L. acidophilus*1 is considered a probiotic microorganism, able to survive passage through gastrointestinal tract in an animal model and prevent intestinal colonization by *V. cholerae* in newborn rabbits.

<sup>2</sup>UCIBIO@REQUIMTE Departamento de Ciências da Vida,  
Universidade Nova de Lisboa, Caparica, Portugal

<sup>3</sup>Mikrobiologisches Institut-Klinische Mikrobiologie Immunologie und Hygiene,  
Friedrich-Alexander Universität Erlangen-Nürnberg, Erlangen, Germany

### **Background**

Facultative and obligate intracellular pathogenic bacteria subvert host cell functions to create an intracellular environment for their replication and persistence. This is achieved by injection of bacterial proteins into the host cell cytoplasm via specialized type 3 or 4 secretion systems, thus reprogramming cellular pathways. Heterologous expression in the *Saccharomyces cerevisiae* yeast model is often used to understand the function of translocated effectors.

### **Objectives**

We report the expression in *S. cerevisiae* of over 30 candidate and cognate effectors from *Chlamydia trachomatis*, *Coxiella burnetii* and *Salmonella enterica* as N-terminal GFP fusions, aimed to study their subcellular localization as a means to gain insight in their function within eukaryotic cells.

### **Methods**

We present data on co-localization with fluorescent markers and the use of a battery of yeast mutants defective at specific membrane traffic stages to address differential cues recognized by these effectors.

### **Conclusions**

Most effectors showed a ubiquitous cytoplasmic distribution, either diffuse or concentrated in foci. Sometimes, as in *Coxiella* CaeA, these foci were consistent with accumulates of unfolded or aggregated protein. However, a few particular effectors displayed specific localizations. Notably, *Coxiella* AnkB was imported into the nucleus and associated to the nucleolus; *C. trachomatis* CT696, *C. burnetii* CBU-77 and *Salmonella* SteA specifically localized to cellular membranes. Particularly, *C. trachomatis* CT696 decorated the plasma membrane, *C. burnetii* CBU-77 localized at vacuolar membranes, and *Salmonella* SteA targeted simultaneously both

membranous systems. The utility of the yeast heterologous system to study the determinants for recognition by bacterial effectors of subcellular eukaryotic compartments will be discussed.

**C. CANIMORSUS AFFECTS COAGULATION BY REDUCING THE ACTIVITY OF VITAMIN K DEPENDENT CLOTTING FACTORS**

K. Hack<sup>1</sup>, J. Douxfils<sup>2</sup>, J.M. Dogné<sup>2</sup>, G.R. Cornelis<sup>1</sup>

<sup>1</sup>URBM, UNamur, Namur, Belgium

<sup>2</sup>Pharmacie, UNamur, Namur, Belgium

**Background**

*Capnocytophaga canimorsus* is a Gram-negative bacterium belonging to the oral flora of dogs. The bacterium causes rare but severe infections in humans that have been bitten or licked. Patients frequently develop severe sepsis with disseminated intravascular coagulation (DIC).

**Objectives**

Considering that several bacteria interact with coagulation factors or platelets, as well as the frequency of bleeding abnormalities in *C. canimorsus* infection, we were interested if *C. canimorsus* interferes with coagulation.

**Methods**

We incubated normal pooled plasma (NPP) with *C. canimorsus* strain 5 (Cc5) and monitored thrombin generation by a calibrated automated thrombogram (CAT) assay. Additionally, clotting times of Cc5 treated NPP were measured. Factor deficient plasma was used to assess the activity of individual coagulation factors in Cc5 treated NPP.

**Conclusions**

Cc5 inhibited thrombin generation and clotting times of NPP incubated with Cc5 were significantly increased. However, pre-treatment of Cc5 with the irreversible serine protease inhibitor AEBSF completely abolished this increase.

We observed a specific impairment of the Vitamin K dependent (VKD) factors, FX, FIX, FII and FVII. We could also show that FX was cleaved by Cc5.

To conclude, our findings suggest a proteolytic mechanism by which Cc5 affects coagulation and which causes degradation of FX.

We are now interested in finding the cleavage site, to see if the other VKD clotting factors are equally degraded and to identify the bacterial protease which mediates the cleavage.

Inhibition of coagulation could promote bacterial dissemination and also aggravate DIC associated bleeding.

<sup>2</sup>Laboratory of Veterinary Anatomy, Kitasato Univ. School of Veterinary Medicine, Towada, Japan

<sup>3</sup>Laboratory of Biomolecular Function, Kitasato Univ. School of Veterinary Medicine, Towada, Japan

<sup>4</sup>Laboratory of Zoonoses, Kitasato Univ. School of Veterinary Medicine, Towada, Japan

**Background**

*Vibrio vulnificus* causes rapid disseminating septicemia by oral infection in infected individuals who have an underlying disease, especially chronic liver diseases. Although the elucidation of specific risk factors for *V. vulnificus* infection in patients with liver diseases is of urgent importance, no appropriate experimental animal model that mimics the liver diseases in this bacterial infection has been available so far.

**Objectives**

Discover the risk factors for *V. vulnificus* infection in liver diseases patients.

**Methods**

To discover these risk factors, we generated a liver disordered mouse by performing bile duct ligation (BDL). The BDL mice were infected with the *V. vulnificus* by orogastric route.

**Conclusions**

Hepatitis developed in the BDL mice, however this did not affect mortality in mice after orogastric administration of *V. vulnificus*, suggesting that the liver disorders caused by the BDL were not risk factors for *V. vulnificus* septicemia. When the dead and surviving mice were compared, *V. vulnificus* could be detected from the spleen only in the dead group. Furthermore, significantly higher numbers of *V. vulnificus* were detected from the intestines in the dead group than in the surviving group ( $p < 0.001$ ). These findings suggested that proliferation of the challenge inoculum in the intestine was needed for the oral infection with *V. vulnificus*, and that the elimination of *V. vulnificus* in the liver and/or spleen plays a critical role in survival of the host.

## **EFFECT OF HYPOBARIC HYPOXIA ON MICROBIAL HOMEOSTASIS AND PATHOLOGICAL CONSEQUENCES IN GUT**

K.C. Mondal<sup>1</sup>, A. Adak<sup>1</sup>, D. Ojha<sup>2</sup>, K. Ghosh<sup>1</sup>, C. Vagvolgyi<sup>3</sup>

<sup>1</sup>Microbiology, Vidyasagar University, Midnapore, India

<sup>2</sup>ICMR Virus Unit, NICED, Kolkata, India

<sup>3</sup>Microbiology, University of Szeged H-6726 Szeged, Szeged, Hungary

### **Background**

At high altitude (HA), hypobaric hypoxia is a hallmark of environmental stress that faced by millions of people like pilgrims, trekkers, scientists and military personnel and they generally suffer from a group of non-specific gastrointestinal complications like anorexia, dyspepsia, nausea, acidity, haematemesis, peptic ulcers, etc. These diseases are mostly related to the alteration of intestinal microbes and their related phenomenon.

### **Objectives**

This experiment was conducted to explore the relationship between the altered atmospheric pressure with the microbial composition, which is the major functional counterpart of GI tract.

### **Methods**

Albino mice were subjected to hypobaric atmospheric pressures (55kpa) in a chemostat for 15 days and after dissection intestinal luminal contents were collected. The population of indicator bacteria were monitored by selective culture based methods and DGGE. The expression of inflammatory markers of intestinal epithelium were evaluated by qPCR and western blot.

### **Conclusions**

The quantity of facultative anaerobes like *Escherichia coli*, other strict (*Bacteroidetes* sp. and *Lactobacillus* sp.) and obligate (*Clostridium perfringens*, *Peptostreptococcus* sp) anaerobes were increased in many folds after exposure to hypoxic environment. The increased level of bacteria and their endotoxins activated p38 MAP kinase and TLR4 pathways which are related to the over expression of inflammatory cytokines and mediators like IL23, IL17F, TNF  $\alpha$ , INOS, COX2 and HIF 1 $\alpha$ . As a result mucosal layers of intestinal wall was severely inflamed and perforated which also documented by SEM studies. These consequences are greatly related to the prognosis of different gastrointestinal ailments developed during hypobaric hypoxic stress at high altitude.

**IRON ACQUISITION MECHANISMS OF THE CYSTIC FIBROSIS (CF) PATHOGEN  
BURKHOLDERIA CENOCEPACIA AND THE CORRESPONDING HOST  
RESPONSE**

W. Niamh<sup>1</sup>, J. Tyrrell<sup>1</sup>, N. Moloney<sup>2</sup>, M. Thomas<sup>3</sup>, S. Doyle<sup>2</sup>, M. Callaghan<sup>1</sup>

<sup>1</sup>Centre for Microbial Host Interactions, Institute of technology Tallaght, Dublin, Ireland

<sup>2</sup>Department of Biology, Maynooth University, Co. Kildare, Ireland

<sup>3</sup>Department of Infection and Immunity, University of Sheffield, Sheffield, United Kingdom

**Background**

*B. cenocepacia*, is a highly antibiotic resistant CF pathogen which produces low molecular weight iron chelators known as siderophores, predominantly ornibactin, to sequester iron in the host. In response to bacterial and fungal infection, mammals produce lipocalins, some of which bind siderophores.

**Objectives**

To characterise ornibactin production by *B. cenocepacia* under different conditions and the resulting host lipocalin response to ferrated ornibactin and to investigate alternative iron acquisition mechanisms by this pathogen.

**Methods**

Ornibactin gene expression detected using real-time PCR and siderophore levels measured using the CAS assay. Utilisation of iron sources assessed using growth assays. Lipocalin 1 (LCN1) was expressed in *E. coli* using the Champion™ pET 100 vector system.

**Conclusions**

This study demonstrated that in iron-depleted cultures siderophore production by *B. cenocepacia* is significantly upregulated by 4 h ( $P < 0.001$ ) with maximal production by 5 h. Furthermore, *B. cenocepacia* can acquire iron from exogenous sources such as host iron binding proteins including ferritin and hemin, and from the *Aspergillus fumigatus* xenosiderophores, fusarinine C and triacetylfusarinine C demonstrating a multifaceted iron acquisition strategy. Host response investigations have determined that recombinant LCN1 binds ferric-ornibactin with high affinity and not unferrated ornibactin. Ongoing studies are examining cellular lipocalin responses and the utilisation of additional xenosiderophores. Understanding the iron acquisition strategies and host responses to this pathogen is warranted given the potential to prevent colonisation by this pathogen if iron acquisition can be compromised.

## **INFECTION OF CAMPYLOBACTER JEJUNI REDUCES CFTR MEDIATED CL- SECRETION IN T-84**

T. Shimohata<sup>1</sup>, S. Negoro<sup>1</sup>, J. Kido<sup>1</sup>, S.H.O. Hatayama<sup>1</sup>, Y.U.R.I. Sato<sup>1</sup>, H. Iba<sup>1</sup>, M. Nakahashi<sup>1</sup>, T. Uebanso<sup>1</sup>, K. Mawatari<sup>1</sup>, A. Takahashi<sup>1</sup>

<sup>1</sup>Department of Preventive Environment and Nutrition,  
Univ of Tokushima Grad Sch of Health Biosciences, Tokushima, Japan

### **Background**

*Campylobacter jejuni* is the common bacteria cause acute gastroenteritis in humans. It has been reported that the *C.jejuni*-infection was caused by very low infective dose, and it suggested that *C.jejuni* might have a resistance system against bacterial clearance system in intestinal tract. The mucus layer in the intestinal tract is the first defense system against bacterial infection, and the condition is well maintained by water movement. Cl<sup>-</sup> transport is closely associated with water efflux on intestine. Cystic fibrosis transmembrane conductance regulator (CFTR) is the major Cl<sup>-</sup> secretory pathway which is activated by cAMP. Dysfunction of CFTR causes dehydration of mucus and accumulation of bacteria in the intestine.

### **Objectives**

CFTR is tightly related with infection of pathogenic bacteria. However, it is not clear how CFTR related with the *C. jejuni*-infection. To elucidate the role of CFTR on *C. jejuni*-infection, we investigated the Cl<sup>-</sup> secretion in T-84 on infection of *C. jejuni*.

### **Methods**

Cl<sup>-</sup> secretion was measured by <sup>125</sup>I<sup>-</sup> efflux on T-84 cells. *C. jejuni*-infection did not change <sup>125</sup>I<sup>-</sup> effluxes in steady state. Next, we confirmed forskolin or prostaglandine E2, agonists of cAMP-dependent Cl<sup>-</sup> secretion, activated <sup>125</sup>I<sup>-</sup> effluxes, which inhibited by CFTR inhibitor.

### **Conclusions**

These indicated that *C. jejuni*-infection suppressed the activation of Cl<sup>-</sup> secretion dependent on CFTR. There were hypothesized that *C. jejuni*-infection effected on water movement and the mucus dehydration, which was related with bacterial clearance system in intestinal tract.

**A STRATEGY OF PATHOGEN STREPTOCOCCUS ESCAPE MAMMALIAN PEPTIDOGLYCAN RECOGNITION PROTEINS KILLING**

J. Wang<sup>1</sup>, J. Tang<sup>2</sup>

<sup>1</sup>*translational medicine centre, No.454 Hospital, Nanjing, China*

<sup>2</sup>*Institute of Clinical Laboratory Medicine,  
PLA Research Nanjing general hospital of Nanjing Military command, Nanjing, China*

**Background**

Our previous work showed that a new GI-type IVC secretion system location in the GI similar as previous described an 89K GI-like structure of *S. suis* named S4GIs is popular in the genus streptococcus.

**Objectives**

To reveal an unknown mechanism of a novel family of peptidyl-proly isomerases (PPIases) named SP1 from S4GIs interact with mammalian peptidoglycan recognition proteins (PGRPs).

**Methods**

In this study, we show that the function of killing bacteria of innate immunity proteins PGRPs could be blocked by protein SP1. We confirmed intracellular concentration of SP1 from streptococcus depends on secretion channel of S4G and increased expression of SP1 could be regulated by the concentration of PGRPs in environment using ELISA and qRT-PCR.

**Conclusions**

In conclusion, this study indicated a new escape way of pathogenicity Streptococcus protects against mammalian innate immunity proteins killing.

## FEMS-2781

### Imaging

## MASS SPECTROMETRY IMAGING OF ACTIVE CORRODING BIOFILMS IN 3 DIMENSIONS USING LASCA MSI

J. Brauer<sup>1</sup>, I. Beech<sup>1</sup>, J. Sunner<sup>1</sup>

<sup>1</sup>Microbiology and Plant Biology, University of Oklahoma, Norman, USA

### Background

Biofilms are highly diverse and complex multispecies microbial assemblages with characteristic spatial, i.e. three-dimensional organization. Elucidating function of a biofilm community would require a detailed characterization not only of the spatial distribution of the sessile organisms but also their respective metabolites.

### Objectives

Mass spectrometry (MS) of homogenized biofilms (and other methods) have shown the importance of bacterial metabolites in the corrosion process. However, as seen in the profilometry map of a corroded coupon (Figure 1), the corrosion and the biofilm that causes it are not homogeneous. In order to gain a better understanding of the MIC process, we need to develop an instrument that can combine MS and spacial information.

### Methods

An ambient mass spectrometry imaging (MSI) system was developed specifically for imaging living biofilms on corroding lab or field samples. The Laser Ablation and Solvent Capture by Aerosol (LASCA) instrument uses an IR laser to collect a 200  $\mu\text{m}$  spot from the sample and analyzes it using a high resolution QToF. A single spot is analyzed in less than 10 seconds, allowing for thousands of spots to be analyzed and built into an ion image (Figure 2). The laser can be tuned to a specific

## Conclusions

We present a system that can create ion images of thick, uneven biofilms in 3 dimensions. We demonstrate the use of LASCA with the correlation of ion images to corrosion damage. Further, method to probe the penetration depth of biocides into a biofilm is presented.

Düsseldorf, Germany

<sup>2</sup>Institute of Bio- and Geosciences IBG-1: Biotechnology,  
Forschungszentrum Jülich GmbH, Jülich, Germany

<sup>3</sup>Institute of Complex Systems (ICS-4 Cellular Biophysics),  
Forschungszentrum Jülich GmbH, Jülich, Germany

#### Background

Genetically encoded fluorescent proteins (FPs), like GFP from the jellyfish *Aequorea victoria*, became one of the most variable and popular *in vivo* reporters in cell biology, microbiology and biomedicine. They can easily be detected by *in vivo* fluorescence techniques thus enabling the non-invasive analysis of complex cellular processes. However, beside the large size and relative slow maturation, a major drawback of GFP and its variants is their strict limitation to aerobic biological systems. This is primarily due to the fact that the autocatalytic synthesis of the chromophore depends on molecular oxygen.

#### Objectives

To conquer these limitations, we developed a new class of small cyan-green fluorescent proteins which can be used in microbes and mammalian cells under aerobic, oxygen-limited as well as anaerobic conditions. These FPs carry flavin mononucleotide (FMN) as chromophore and are thus termed FMN-binding fluorescent proteins (FbFPs).

#### Methods

To evaluate the applicability of FbFPs, the photophysical properties including the fluorescence spectra and brightness have been characterized and further improved. Furthermore, *in vivo* studies demonstrated their broad usability as reporter in (facultative) anaerobic bacteria and for bioprocess engineering. In addition, FbFPs were also be used to generate novel genetically encoded biosensors allowing the ratiometric intracellular monitoring of essential environmental parameters including molecular oxygen and pH.

#### Conclusions

The unique properties of FbFPs render them particularly valuable as *in vivo* tools for fluorescence imaging, quantitative *in vivo* analysis of gene regulation, protein

localization and bio-sensing.

**TOWARDS STRUCTURE DETERMINATION OF MACROMOLECULAR  
COMPLEXES WITHIN THEIR NATIVE ENVIRONMENT**

R. Ravelli<sup>1</sup>, A. Siroy<sup>1</sup>, S. Neumann<sup>2</sup>, D. Chen<sup>1</sup>, K. Notelaers<sup>1</sup>, Y. Xue<sup>1</sup>, F. Nijpels<sup>1</sup>,  
P. Peters<sup>1</sup>

<sup>1</sup>*M4I Division of Nanoscopy, Maastricht University, Maastricht, Netherlands*

<sup>2</sup>*Life Science Division, FEI, Eindhoven, Netherlands*

**Background**

Structures of macromolecular complexes are traditionally solved by X-ray crystallography, requiring crystals and bright X-ray sources to obtain resolutions at which side-chain densities can be seen. Last year, a revolution has taken place in the field of single-particle cryo-electron microscopy (EM), resulting in numerous high-resolution un-crystallisable structures. These breakthroughs have been made possible by the conjunction of a new generation of microscopes, detectors, and software.

In single-particle EM, thousands of noisy images of individual biomolecules are computationally combined into one 3D model. Best results are obtained when the sample of interest has been extensively purified and stabilized. During these steps, the biological context disappears, interacting partners dissociate, and unforeseen conformations could be induced.

**Objectives**

Ideally, single-particle like methods could be applied to biomolecules within their native environment. Unfortunately, almost all eukaryotic cells are too thick to be imaged by EM.

Our lab has set the long term goal to derive structures from biomolecules within their cellular environment. We label complexes with fluorescent tags to localize regions of interest (ROI) within vitrified cells. The coordinates of these ROIs are, together with the sample, transferred under cryogenic conditions into a dual-beam FIB/SEM system to trim the ROIs into ca 150nm thin lamella. Finally, the trimmed sample is cryogenically transferred to a high-end transmission EM for subsequent imaging at different orientations.

**Methods**

In here, we will report on the first results obtained with our cryo-correlative workflow on mycobacteria.

**Conclusions**

We discuss challenges and opportunities, the latter including developments such as phase plates and super-resolution microscopy.

**AUTOMATED SEGMENTATION OF INDIVIDUAL CELLS AT PHASE CONTRAST MICROSCOPY IMAGES**

J. Soukup<sup>1</sup>

<sup>1</sup>*Laboratory of signal and image processing, ICS FFPW USB, Nové Hradý, Czech Republic*

**Background**

Nowadays, computer processing of microscopic images is becoming more common as a part of research in the field of cell science, replacing slow and time-consuming manual processing by human experts. A challenging task is for example to process images of live mammalian cancer cells from a phase contrast microscope.

**Objectives**

When processing the time-lapse images of live cells, the main goal is to describe the movement and behaviour of individual cells. There are many methods available in the cases when individual cells are separated from each other, However, separating individual cells from colonies or even from cell monolayers is much more difficult.

## **Methods**

We developed a novel algorithm for segmentation of individual cells. First part separate the cells from the background and it is based on the differences in time between consecutive images and a combination of sophisticated thresholding, blurring, and morphological operations. It is fast and precise. The second part of our algorithm separates individual cells in the clusters. It uses the halos between cells (thresholding and modified skeletonization) and fills the missing parts by connecting the hanging branches of the skeleton via Dijkstra algorithm.

## **Conclusions**

We tested the algorithm on images of four cell types acquired by two different microscopes, evaluated the precision of segmentation against manual segmentation performed by a human operator. We created the software which implements our segmentation method. We added the possibility to modify the resulting segmentation. User can modify the result by merging or splitting the cell regions that was found by out algorithm.

## **STRUCTURAL STUDIES OF LEGIONELLA EFFECTORS**

K. Wong<sup>1</sup>, Y. Zhang<sup>1</sup>, G. Kozlov<sup>1</sup>, K. Gehring<sup>1</sup>

<sup>1</sup>Biochemistry, McGill University, Montreal, Canada

### **Background**

*Legionella pneumophila* is a Gram-negative bacterium and is the causative agent of Legionnaires' disease. The Dot/Icm type IV secretion system (T4SS) is one of the key virulence factors of *L. Pneumophila*. By transferring effector proteins into the host cell, the bacterium is able to replicate inside human alveolar macrophages by rapidly altering the normal host endocytic pathway after uptake. Currently, about 300 Icm/Dot dependent effectors have been identified in *L. pneumophila*; however, the biochemical functions for most of these proteins remain unknown.

### **Objectives**

Lpg1496 is an effector protein containing a conserved sequence of the SidE family in its C-terminal region. The SidE family members are present early during intracellular replication and localize to the cytoplasmic face of the replicative phagosome upon translocation. No information on other regions of lpg1496 has been available.

### **Methods**

We are exploring the three-dimensional structure of lpg1496 to probe for possible biochemical functions using structural similarity to proteins or domains of known function.

### **Conclusions**

Here, we identified two novel regions of sequence similarity in lpg1496 and showed that they form independently folded domains. Moreover, we have determined high-resolution crystal structures of these domains. Each domain consists of two  $\alpha$ -helices flanked by four  $\beta$ -strands on one side and four  $\beta$ -strands on the other side. Furthermore, we obtained the structure of the conserved C-terminal domain that shows structural similarity to HD domains and possesses phosphodiesterase activity. These studies will lead to a better understanding of the functional role of lpg1496 in *Legionella pneumophila*, and may contribute to the development of novel therapeutic treatments for Legionnaires' disease.

**NOVEL BACILLUS THURINGIENSIS ISOLATES WITH LARVICIDAL ACTIVITY AGAINST THE MOSQUITO VECTOR, CULEX PIPIENS**

A. Ali<sup>1</sup>, T. El-Kersh<sup>2</sup>, H. Hosain<sup>3</sup>

<sup>1</sup>Zoology, King Saud University, Riyadh, Saudi Arabia

<sup>2</sup>Clinical Laboratory Sciences, King Saud University, Riyadh, Saudi Arabia

<sup>3</sup>Plant Protection, King Saud University, Riyadh, Saudi Arabia

**Background**

The outbreak of mosquito vectors, the incidence of mosquito-borne diseases and the resistance of mosquitoes to conventional pesticides have recently caused a panic to the official authorities in the endemic countries. The bacterium *Bacillus thuringiensis* (*Bt*), a safe eco-friendly entomopathogenic biocontrol agent, is widely used to complement the chemical control in integrated mosquito control measures.

**Objectives**

This study was conducted to identify native mosquitocidal *Bt* isolates to be utilized in the battle against insecticides-resistant mosquito populations.

**Methods**

*Bt* isolates have been recovered from different environmental samples collected from different locations throughout Saudi Arabia. Their mosquitocidal activities were tested against *Culex pipiens* 3<sup>rd</sup> instar larvae compared to that of the reference *B. t. israelensis* (*Bti*-H14) strain. Three isolates were almost as active as *Bti*-H14, showing LC<sub>50</sub> of 4.2-4.8 µg/ml. Seven isolates showed 1.6-5.4 times more toxic than that of *Bti*-H14 (LC<sub>50</sub> of 0.91-3.03 v 4.88 µg/ml). Histopathological examination of the *Bt*-63 isolate-treated larvae showed cellular and subcellular alternations in midgut epithelia similar to that caused by *Bti*-H14.

**Conclusions**

Data of this study showed that spore-crystal mixtures of 7 native locally isolated *Bt* were higher mosquito larvicidal compared to that of *Bti*-H14. Molecular characterization of these potentially active isolates and their toxic parasporal protein crystals are currently being investigated. This study may lead to the identification of mosquitocidal *Bt* isolate(s) that could contribute to the battle against mosquito

vectors.

## **EFFECT OF GUT MICROBES ON THE EFFICACY OF BT MAIZE AGAINST LEPIDOPTERAN STEMBORERS**

*M. van Staden<sup>1</sup>, S. Claassens<sup>1</sup>, C. Bezuidenhout<sup>1</sup>, J. van den Berg<sup>2</sup>*

<sup>1</sup>*Microbiology, North-West University, Potchefstroom, South Africa*

<sup>2</sup>*Zoology, North-West University, Potchefstroom, South Africa*

### **Background**

The evolution of resistance in agricultural pests to Cry proteins threatens the sustainable use of genetically modified Bt crops. The specific mechanisms of resistance are not well understood. According to the gut microbiota theory, extensive cell lysis caused by Cry proteins provide gut microbes access to the hemocoel where they germinate and reproduce, causing septicemia and death of the host.

### **Objectives**

The main objective of this study was to determine whether microbes present in the mid-gut of *Busseola fusca* influence the efficacy of Cry 1Ab proteins.

### **Methods**

Larvae were collected from maize fields and dissected to excise the mid-gut. Mid-gut contents (intestinal bacteria) were enumerated on general media. Different morphological types were selected to test the antibiotic susceptibility of the bacteria. The most effective bacteriostatic and bactericidal antibiotics were used and the morphological types were exposed to different concentrations of these to visualise the effects of the antibiotics. This consisted of growth curve studies on all the selected bacteria. A mixture of ciprofloxacin, ampicillin and doxycycline (500 µg/ml) was incorporated into an artificial diet. Stemborer larvae were allowed to feed on this for 7 days. These larvae were then placed on Bt maize (MON810) plant material expressing Cry proteins. Larvae actively fed on the plant material.

### **Conclusions**

Results suggest that by placing antibiotic reared larvae on a Bt plant, the absence of the mid-gut microbes contributed to larval survival on Bt maize.

**GUT MICROBES OF BUSSEOLA FUSCA (LEPIDOPTERA: NOCTUIDAE)**

M. Snyman<sup>1</sup>, A.K. Gupta<sup>1</sup>, C. Bezuidenhout<sup>1</sup>, S. Claassens<sup>1</sup>, J. van den Berg<sup>2</sup>

<sup>1</sup>Microbiology, North-West University, Potchefstroom, South Africa

<sup>2</sup>Zoology, North-West University, Potchefstroom, South Africa

**Background**

Genetically modified maize plants are engineered to express insecticidal toxins derived from the bacterium *Bacillus thuringiensis*. However, field-evolved resistance of African maize stemborers (*Busseola fusca*) against Bt-maize has developed and spread throughout South Africa. Studies suggested (1) that gut bacteria are required for *B. thuringiensis*-induced mortality in most Lepidoptera species and (2) that the toxicity of *B. thuringiensis* depends on microbial community interactions within the gut.

**Objectives**

This study aimed to identify the diversity of gut-associated bacteria by both culture-dependent and culture-independent approaches.

**Methods**

A total of 133 bacterial strains were isolated from the midgut of *B. fusca* larvae collected from 30 different sites. Molecular phylogenetic analyses of 16S rRNA gene sequences revealed bacteria affiliated to *Proteobacteria*, *Actinobacteria*, and *Firmicutes*. Taxonomic distribution of these sequences placed the isolates into 20 different genera. The majority of bacteria identified were belongs to the genera *Enterococcus*, *Klebsiella*, and *Bacillus*. Culture-independent methods involved the denaturing gradient gel electrophoresis fingerprinting (DGGE), and sequence analyses of a 16S rRNA gene from the excised band supported culture recovery results. However, additional bacterial taxa not determined via culture recovery were revealed using this methodology and included members of the genera *Chryseobacterium*, *Lactobacillus*, *Lactococcus*, and *Spiroplasma*.

**Conclusions**

Some sequences represent hitherto uncharacterized novel organisms that may have not been characterised yet. The *Busseola fusca* gut represents an intriguing and unexplored niche for analyzing microbial ecology, which will provide opportunities for research involving the impact of diverse and dynamic microbial communities on developing resistance against Bt-maize.

**PRESENCE OF WOLBACHIA SP. IN DIFFERENT POPULATIONS OF CTENOCEPHALIDES FELIS: DEMOGRAPHIC HISTORY OR A WOLBACHIA SELECTIVE SWEEP?**

C. Cutillas<sup>1</sup>, A. Zurita<sup>1</sup>, M. de Rojas<sup>1</sup>, R. Callejon<sup>1</sup>

<sup>1</sup>Microbiology and Parasitology, UNIVERSITY OF SEVILLE, Seville, Spain

**Background**

The cat flea, *Ctenocephalides felis*, is the most common flea species found on cats and dogs worldwide parasitizing a wide range of hosts. It has long been recognized that many arthropods carry passenger micro-organisms. *Wolbachia* alone infects in excess of 20% of insect species at any point in time. *Wolbachia*-infected species have been found to harbour lower levels of mtDNA diversity in closely related uninfected species.

**Objectives**

At the present work we carried out a molecular and phylogeographical study of *Ctenocephalides felis* and *C. canis* from different geographical regions (Spain, South Africa and Iran). Furthermore, the presence of *Wolbachia* sp. and its influence in these populations has been tested.

**Methods**

Molecular studies were based on the amplification and sequentiation of ribosomal DNA (Internal Transcribed Spacer 2, and 18S gene) and mitochondrial DNA (*cytochrome oxidase c-1* gene).

**Conclusions**

The presence of *Wolbachia* sp. was detected in the majority of fleas from different localities. The ribosomal data showed a great homology between all the populations of *C. felis* regardless the geographical origin but significative differences respect to *C. canis*. Nevertheless, *cytochrome oxidase c-1* sequences revealed significative differences in the population of *C. felis* from South Africa, appearing these sequences with high homology with that of *C. canis*. The endosymbiont *Wolbachia* could be responsible for selective sweeps on mtDNA variability within species. We suggest an introgression of mtDNA and *Wolbachia* between *C. felis* and *C. canis*.

## **ANALYSIS OF THE IMPACT OF IRRADIATION ON SODALIS IN THE TSETSE FLY *GLOSSINA MORSITANS MORSITANS***

G. Demirbas Uzel<sup>1</sup>, A. Parker<sup>1</sup>, R. Mach<sup>2</sup>, K. Bourtzis<sup>1</sup>, M. Vreysen<sup>1</sup>, A. Abd-Alla<sup>1</sup>

<sup>1</sup>Insect Pest Control Laboratory Joint FAO/IAEA Division of Nuclear Techniques in Food and Agriculture, International Atomic Energy Agency, Vienna, Austria

<sup>2</sup>Vienna University of Technology, Institute of Chemical Engineering, Vienna, Austria

### **Background**

Tsetse flies are the sole cyclical vectors of the African trypanosomosis that causes sleeping sickness in humans and nagana in animals. *Glossina* species have established symbiotic relationships with three bacterial species: *Wigglesworthia glossinidia*, *Sodalis glossinidius*, and *Wolbachia pipientis*, mainly known as a reproductive symbiont. A salivary gland hypertrophy virus that affects reproduction of infected flies has been reported. Vector control remains the most effective approach for sustainable management of African trypanosomosis. The sterile insect technique (SIT) has proven to be such an effective method and it is based on the mass production of the targeted insect, the sterilization by irradiation, and the sequential release of sterile males.

### **Objectives**

Such releases in endemic areas might increase the disease incidence before achieving eradication. Therefore, the development of symbiont-based strategies to produce tsetse strains refractory to trypanosome infection would be ideal for SIT programmes. One approach which is currently under consideration is to modify *Sodalis* to produce anti-trypanosome factor(s) in the released sterile males.

### **Methods**

We investigated the impact of irradiation on the establishment of *Sodalis* in the tsetse fly *Glossina morsitans morsitans*

### **Conclusions**

The results indicate that irradiating 5-7 days old male flies with 110 Gy does not increase the mutation rate, as assessed in 15 genes, but it does have a negative impact on the replication rate of *Sodalis* and the salivary gland hypertrophy virus. In contrast the irradiation treatment increased the prevalence of *Wolbachia*. These data are discussed in the frame of combining a symbiont-based and SIT-based control approaches.

## **QUALITATIVE AND QUANTITATIVE ANALYSIS OF MICROBIAL DIVERSITY BY PYROSEQUENCING IN TETRANYCHUS URTICAE**

D.H. Kwon<sup>1</sup>, S.H. Lee<sup>2</sup>

<sup>1</sup>Research Institute of Agriculture and Life Sciences, Seoul National University, Seoul, Korea

<sup>2</sup>Department of Agricultural Biotechnology, Seoul National University, Seoul, Korea

### **Background**

Because of its extreme polyphagous nature, *Tetranychus urticae* is a good model organism to study the rapid adaptation mechanisms to various kinds of host plant toxins and acaricides. The symbiotic microorganism has been known as a pivotal factor in such chemical adaptation of many invertebrates. In *T. urticae*, several symbiotic bacteria (*Wolbachia*, *Cardinium*, etc) have been identified but research has been limited to the elucidation of their functional roles in cytoplasmic incompatibility.

### **Objectives**

Analysis of overall symbiotic bacterial composition in *T. urticae* is necessary as a cornerstone for the integrative study on its host adaptation and acaricide resistance development.

### **Methods**

16S rRNA pyrosequencing was conducted for nine *T. urticae* populations with different acaricide resistance properties (7 green types and 2 red types) with GS Junior Sequencing system (Roche, Branford, CT, USA) and data analysis was performed by CLcommunity program (Chunlab Inc., Seoul, Korea).

### **Conclusions**

The operational taxonomic unit by CD-HIT and TBC methods were estimated as  $85.3 \pm 22$  and  $737 \pm 220$  in average, respectively. Most bacterial species (>99%) were categorized in the order Rickettsiales mainly composed of *Wolbachia* spp. and *Rickettsia* spp. except for the acaricide-susceptible UD strain. The UD strain was composed of *Wolbachia* spp. (43.4%) and *Flavobacterium* (53.6%). Green- and red-type mites were grouped into different clades in the cluster analysis using the quantitative and qualitative traits, suggesting that the microbial diversity might be related with the phenotypic characters of body color. Further analysis would be

necessary to elucidate the functional roles of endosymbiont bacteria in regulating the intrinsic physiology of *T. urticae*.

**FEMS-0742**

**Insect-microbes interactions**

**ANALYSIS OF YEAST-LIKE SYMBIOTE DIVERSITY IN THE BROWN PLANTHOPPER (BPH), NILAPARVATA LUGENS STÅL, USING A NOVEL NESTED PCR-DGGE PROTOCOL**

X. Yu<sup>1</sup>, Y. Hou<sup>1</sup>, Z. Ma<sup>1</sup>, S. Dong<sup>1</sup>

<sup>1</sup>College of Life Sciences, China Jiliang University, Hangzhou, China

**Background**

Yeast-like symbiotes (YLS) are endosymbionts that are intimately associated with the growth, development, reproduction of their host, the brown planthopper, *Nilaparvata lugens* (Hemiptera: Delphacidae). However, it is unclear how many species of YLS are found within *N. lugens* and how they are related to each other.

**Objectives**

In order to overcome the difficulty in detecting low numbers of YLS in BPH or culturing the YLS *in vitro*, in this study, we developed a novel strategy, nested PCR–DGGE approach, which was used to analyze the diversity of YLS.

**Methods**

The nested PCR protocol was developed as follows: firstly, the 18S rDNA gene and 5.8S-ITS gene were amplified using fungal universal primers. Subsequently, these products were used as a template in a second PCR with primers ITS1GC-ITS2, ITS1FGC-ITS2 and NFGC-NR, which was suitable for DGGE. Using this highly specific molecular approach, we found several previously detected fungi: *Noda*, *Pichia guilliermondii*, *Candida* sp., and some previously undetected fungi, such as *Saccharomycetales* sp., *Debaryomyces hansenii* and some uncultured fungi.

**Conclusions**

To the best of our knowledge, this is the first study to analyze the diversity of YLS in BPH by using the PCR-DGGE system. This methodological approach can be used to assess the relationship between variation in planthopper performance and YLS community.

## **GENETIC BASIS OF CYTOPLASMIC INCOMPATIBILITY CAUSED BY CARDINIUM**

E. Mann<sup>1</sup>, C.M. Stouthamer<sup>2</sup>, S.E. Kelly<sup>2</sup>, M.S. Hunter<sup>2</sup>, S. Schmitz-Esser<sup>1</sup>

<sup>1</sup>Department for Farm Animals and Veterinary Public Health,  
Institute for milk hygiene milk technology and food science, Vienna, Austria

<sup>2</sup>University of Arizona, Department of Entomology, Tucson, USA

### **Background**

Endosymbionts of arthropods that cause cytoplasmic incompatibility (CI) manipulate host reproduction: bacteria in infected males sabotage the reproduction of uninfected mates, such that the relative fitness of uninfected females is depressed. *Cardinium* (phylum: *Bacteroidetes*) is the only bacterial lineage besides *Wolbachia* known to cause CI.

### **Objectives**

Identify genes involved with CI and host interactions by transcriptional profiling of a CI-inducing *Cardinium* in male and female parasitoid wasps (*Encarsia pergandiella*) and genome sequencing of four *Cardinium* strains causing different phenotypes.

### **Methods**

RNA was isolated from 1-3 day old male and female *Encarsia pergandiella* and bacterial mRNA was enriched using the Ribo-Zero™ Magnetic Gold Epidemiology Kit. Female and male samples were sequenced with Illumina Hi-Seq. The transcriptome was analyzed by mapping reads against the *Cardinium hertigii* genome. *Cardinium* genomes were also sequenced with Illumina HiSeq, assembled using reference-based and *de novo* assembly strategies and annotated using RAST.

### **Conclusions**

First genome comparisons revealed evidence for distinct differences between *Cardinium* strains causing different phenotypes such as the absence of the biotin synthesis pathway in parthenogenesis-inducing *Cardinium*. Currently, the metatranscriptome is analyzed in more detail, focusing on sex-specific gene expression of candidate proteins for CI and eukaryotic cell cycle regulation. A ubiquitin-specific protease and a ubiquitin ligase, genes of the putative anti-feeding prophage, and other genes involved in host cell interaction were highly expressed. We expect that the results of the transcriptome sequencing and comparison of *Cardinium* genomes causing different phenotypes will reveal first deep insights into the mechanisms of reproductive manipulation in *Cardinium*.

**Insect-microbes interactions**

## **DIETARY AND PHYLOGENETIC DETERMINANTS OF GUT COMMUNITY STRUCTURE IN HIGHER TERMITES**

A. Mikaelyan<sup>1</sup>, C. Dietrich<sup>1</sup>, T. Köhler<sup>1</sup>, D. Sillam-Dussès<sup>2</sup>, A. Brune<sup>1</sup>

<sup>1</sup>*Department of Biogeochemistry, Max Planck Institute for Terrestrial Microbiology, Marburg, Germany*

<sup>2</sup>*Laboratory of Experimental and Comparative Ethology (LEEC), University of Paris, Paris, France*

### **Background**

The microbial symbionts of termites play critical roles in the digestion of lignocellulose. Unlike wood-feeding lower termites, which are associated with cellulolytic flagellates, higher termites harbor an entirely prokaryotic gut microbiota. Simultaneously, they have considerably extended the range of their diet to lignocellulosic plant litter in various stages of humification. Since the same dietary specializations have evolved in different evolutionary lineages, higher termites offer the unique opportunity to study potential drivers of microbial community structure in the intestinal environment.

### **Objectives**

To assess the influence of host phylogeny and diet on the composition of the termite gut microbiota.

### **Methods**

We analyzed the bacterial microbiota in the hindgut of 19 higher termite species from different feeding guilds using Illumina sequencing of amplified 16S rRNA genes. Sequence reads were taxonomically classified using a curated reference database and subjected to phylogenetic and statistical analysis.

### **Conclusions**

The high similarity in the bacterial gut microbiota among the wood-feeding and humivorous members of different host lineages identified diet as a strong determinant of microbial community structure in higher termites. At higher taxonomic resolution, however, individual bacterial taxa showed a strong specificity for certain host groups, suggesting they are coevolving with their respective hosts. Nevertheless, evidence of co-cladogenesis is scarce and most bacterial lineages may not co-speciate with their respective hosts over a longer evolutionary time. Rather, the observed patterns of

host restriction seem to be enforced by a combined selection by microhabitat and ecological niche, enhanced by a vertical transmission of symbionts facilitated by the social lifestyle.

**Δ-ENDOTOXINS OF BACILLUS THURINGIENSIS FORM AMYLOID FIBRILS  
THERE ARE INVOLVED IN THE FORMATION OF PARASPORAL CRYSTALS**

*T. Yudina*<sup>1</sup>, *D. Guo*<sup>1</sup>, *I. Zalunin*<sup>2</sup>, *A. Netrusov*<sup>1</sup>

<sup>1</sup>*Microbiology, Lomonosov Moscow State University, Moscow, Russia*

<sup>2</sup>*Genetic, Research Institute for Genetics and Selection of Industrial Microorganisms, Moscow, Russia*

**Background**

The δ-endotoxins of the entomopathogenic bacterium *Bacillus thuringiensis* are multifunctional, so they are not only with highly specificity destroy invertebrate sensitive cells, but have an antimicrobial effect, leading to the destruction of cell walls and cytoplasmic membranes of some microorganisms like activities of others antimicrobial peptides and proteins (1, 2). We discovered for the first time the amyloid fibrils (AF) relating with parasporal crystals of *B. thuringiensis*.

**Objectives**

The crystals of *B. thuringiensis* subspecies: *kurstaki*, *israelensis*, *amagiensis* were the objects of our study.

**Methods**

Crystals and AF we studied using transmission electron microscopy. To confirm the formation of AF observed their interaction with the dye Congo red in the polarization interference microscope. Molecular mass of proteins was determined by PAGE electrophoresis.

**Conclusions**

δ-Endotoxins are capable to forming the AF having different thicknesses (like the previously studied AF). The degree of ordering of the AF increased near the crystals. Our research have given us reason to believe that the *B. thuringiensis* AF are involved in the formation of parasporal crystals. We discuss the ecological role and practical importance of these AF.

## **TARGETING GUT MICROBES: NOVEL APPROACH FOR INSECT CONTROL**

C.D. Patil<sup>1</sup>, S.V. Patil<sup>1</sup>

<sup>1</sup>SCHOOL OF LIFE SCIENCES, North Maharashtra University, Jalgaon, India

### **Background**

Several insects are significantly affecting global economy through insect borne diseases in Agricultural and public health sector. Developing resistance towards frontline insecticides is the major challenge in insect control. Metabolic resistance is one of the major forms of resistance mechanisms. Role of insect gut microbes in supporting normal growth and development of insect is well documented. However, the role of insect gut microbes in developing resistance & favoring insect adaptation has not yet been deeply investigated. Targeting insect gut microbes could lead to unforeseen avenues for effective management of harmful insects.

### **Objectives**

To development novel strategy of insect control by targeting insect gut microbes.

### **Methods**

Two model insects are used in the present study malaria vector *Anopheles stephensi* and cotton pest mealybug *Maconellicoccus hirsutus*. Insect guts were cured with selected antibiotic treatment. These cured mosquito larvae's and Mealybug were observed for pesticide susceptibility. *M. hirsutus* were observed for fecundity, crawler and adult development wax content. While *An. stephensi* were tested for altered susceptibility against *Bacillus thuringiensis israelensis* treatment

### **Conclusions**

We observed that gut microbes cured mosquito larvae and Mealy bug became more susceptible to pesticide and environmental factors. Hence we put forward interesting effective vector or pest control strategy by targeting gut microbes.

**MICROBIAL DIVERSITY IN GALL-INDUCED AND NON-INDUCED APICAL BRANCHES OF HAPLOPAPPUS FOLIOSUS (ASTERACEAE)**

V. Zadjelovic<sup>1</sup>, E. Severino<sup>1</sup>, C. Dorador<sup>1</sup>, C. Villagra<sup>2</sup>

<sup>1</sup>Laboratory of Microbial Complexity and Functional Ecology Bioinnovation Center CB IA, University of Antofagasta, Antofagasta, Chile

<sup>2</sup>Entomology Institute, Metropolitan University of Educational Sciences, Santiago, Chile

**Background**

Plant galls are abnormal vegetative growths that involve the participation of insect, bacteria, fungi and nematodes to induce growth. The role of microbial associations in gall formation are however, unknown.

**Objectives**

Our objective was to describe and compare the culturable diversity of bacteria and fungi from galled and non-galled apical branches in *Haplopappus foliosus*, an endemic flowering plant of the Asteraceae from Chile.

**Methods**

Fungal and bacterial isolates were grown in Sabouraud and enriched nutrient broth respectively. Molecular identification of the isolates was performed by analysis of 16SrRNA, 18SrRNA and ITS DNA genes analysis. Bioactive fungal secretions were analysed by HPLC-MS.

**Conclusions**

Our results indicate that there was a significant difference in microbial communities associated with cecidia and non-galled tissue, comprising 72% and 28% respectively. According to the Margalef index (10.25 galls and 1.95 non-galled) there was a high presence of fungi in galls 52% (n=31), bacteria 43% (n=26) and yeast 5% (n=3). Interestingly, some bacterial isolates have been described as PGPR, such as *Massilia sp.* and *Bacillus simplex*, and cellulose degrading *Cellulomonas denverensis*. Fungal isolates, have been characterized by their capacity to secrete bioactive compounds and we are currently using analytical techniques to determine potential function of these secretions in the formation of the gall association.

Knowing the microbial composition in galled and non-galled tissue will allow us to identify potential key roles in the formation of cecidia structures and develop future biotechnological strategies to prevent gall formation in endemic plants of the region.

<sup>3</sup>*Zoological Institute, Kiel University, Kiel, Germany*

<sup>4</sup>*Open Lab "Extreme biology", Kazan Federal (Volga Region) University, Kazan, Russia*

#### **Background**

There are organisms of different complexity, which can survive complete water loss conditions. Among them are bacterial and fungal spores, plant seeds, nematodes, rotifers, tardigrada. The most complex known organism with ability to withstand severe dehydration is larvae of African chironomid *P. vanderplanki*. During water depletion, larvae cells pump out water and accumulate trehalose and a number of protective proteins – Lea, Hsp, thioredoxins, etc.

#### **Objectives**

Here we attempted to investigate the bacterial community inhabiting the gut of sleeping chironomid *Polypedilum vanderplanki*, an insect able to survive complete dehydration by induction of special metabolic state anhydrobiosis.

#### **Methods**

To assess the variability of gut microbiota in *P. vanderplanki* larvae, we performed 454 pyrosequencing of 16S rRNA gene.

#### **Conclusions**

Comparison of larvae maintained under controlled laboratory conditions for more than 10 years and freshly collected from wild allowed to identify the core microbiota. Interestingly, representatives of larvae core microbiota were absent in soil samples suggesting true associations with host. By production of germ free larvae we showed that the absence of bacteria does not affect the rate of successful anhydrobiosis. However, sterile animals are suffering from the fungal infestation. We revealed that some isolated bacterial strains have antagonistic activity against fungi. Moreover, we found that during rehydration millions of virus-like particles are accumulating in the interspace between gut epithelium and peritrophic membrane. These viruses could promote the development of anhydrobiosis phenomenon in *P. vanderplanki* insect. The work is performed according to the Russian Government Program of Competitive Growth of Kazan Federal University.

**METABOLIC ACTIVITIES OF STRICTLY AND FACULTATIVELY ANAEROBIC GUT BACTERIA AND THEIR INTERACTIONS IN A GERM-FREE COCKROACH MODEL**

D. Tegtmeier<sup>1</sup>, C. Thompson<sup>1</sup>, C. Schauer<sup>1</sup>, A. Brune<sup>1</sup>

<sup>1</sup>Biogeochemistry, Max Planck Institute for Terrestrial Microbiology, Marburg, Germany

**Background**

The diverse microbial communities in the guts of termites and cockroaches represent a complex metabolic network of individual populations. In view of the special microenvironmental conditions within the gut and possible interactions among the microbiota, it is essential to investigate in how far the metabolic properties of pure cultures reflect their activities in their natural environment.

**Objectives**

To develop a protocol for the inoculation of germ-free cockroaches with defined cultures of autochthonous gut bacteria and to compare the metabolic profiles of the isolates in pure culture (*in vitro*) with their activities and interactions in the gut environment (*in situ*).

**Methods**

Pure cultures of gut bacteria were isolated from the cockroach *Shelfordella lateralis*. After inoculation of germ-free cockroaches, the strains were quantitated and localized *in situ* using qPCR, GFP-fluorescence and FISH. Gut conditions and metabolites were analyzed using microsensors, HPLC and GC.

**Conclusions**

The germ-free cockroach model provides first insights into the factors affecting the metabolism of the gut microbiota in their native environment. The strictly anaerobic *Fusobacterium* sp. (strain FuSL) and the facultatively anaerobic enterobacterium (strain EbSL) exclusively colonized the hindgut. Both strains showed high cell densities in mono-association, but the abundance of strain FuSL was much lower when co-inoculated with strain EbSL. Oxygen strongly influenced the metabolic products both under *in vitro* and *in situ* conditions. The availability of oxygen in the gut would also explain why the anaerobic strain FuSL is outcompeted by the

facultatively anaerobic strain EbSL, which should achieve higher growth yields under microoxic conditions at the gut wall.

#### **EVALUATION OF ANTIBACTERIAL EFFECT OF AMERICAN COCKROACH HEMOLYMPH ON SOME NOSOCOMIAL PATHOGENIC BACTERIA**

A. zahirnia<sup>1</sup>, M. Latifi<sup>1</sup>, M. Alikhan<sup>2</sup>

<sup>1</sup>Medical Entomology, Hamadan University of Medical Sciences, Hamadan, Iran

<sup>2</sup>Medical Microbiology, Hamadan University of Medical Sciences, Hamadan, Iran

#### **Background**

Insects due to their long evolutionary history are able to recognize many pathogenic microorganisms and defend against them. Today, due to the development of resistance to synthetic antibiotics, researchers are trying to apply insect immune-derived products.

#### **Objectives**

This study was planned to investigate the antibacterial effect of the American cockroach (*Periplaneta Americana*) hemolymph on susceptible and resistant strains of nosocomial bacteria.

#### **Methods**

Adult cockroaches were reared in insectarium ( $25 \pm 2$  and 60% humidity) .To stimulate their immune system,  $20 \mu\text{l}$  of  $10^6$  *Escherichia coli* cells were injected into coelom .After 6 hours ,induced hemolymph were collected . The antibacterial effect of extracted hemolymph were assayed in the agar diffusion method on susceptible and resistant bacteria to antibiotics of ceftazidime, imipenem and, methicillin including, susceptible *E. coli* strain "ATCC 25922"& "PTCCIBRC-M 10708", *Staphylococcus aureus* "ATCC25923", *Pseudomonas aeruginosa* "ATCC 27853" and, resistant strains of *E.coli*, *Pseudomonas aeruginosa* and, *Staphylococcus aureus* that were isolated from the hospital environment and stored in bank of bacteria. Also, non-induced hemolymph effect was evaluated on the same bacteria.

#### **Conclusions**

Evaluation of induced hemolymph effect on types of strains showed that induced hemolymph affected about 75% of susceptible bacteria strains ( $P\text{-Value} < 0.001$ ), whereas it had no effect on resistant strains. Among bacterial tested, ceftazidime-sensitive *E. coli* ( PTCC ( ,ceftazidime- sensitive *E. coli* (ATCC 25922), and methicillin-sensitive *S. aureus* (ATCC 25923) showed sensitivity to induced hemolymph ( $P\text{-Value} < 0.001$ ).

These results showed that stimulation of immunity system American cockroach leading to production of antibacterial proteins and peptides which have inhibitory effect on bacterial depending on the bacterial strains and their sensitivity.

**THE ACTIVATION OF THE AUTOPHAGIC PROCESS BY EIEC PROVIDES A SMALLER SPREAD IN THE HOST CELLS.**

H. Santos<sup>1</sup>, R. Ramos Massaro<sup>1</sup>, A. Ramos Moreno<sup>2</sup>, L. Gonçalves Ferreira<sup>1</sup>,  
M. Baquerizo Martinez<sup>1</sup>

<sup>1</sup>Clinical Chemistry and Toxicology Dept, University of São Paulo, São Paulo, Brazil

<sup>2</sup>Department of Microbiology, University of São Paulo, São Paulo, Brazil

**Background**

Autophagy has been described as an intrinsic host defense system for recognizing and eliminating intracellular-invading bacterial pathogens. However, invading pathogens have evolved mechanisms to avoid autophagic detection. Enteroinvasive *Escherichia coli* (EIEC), an important diarrheagenic *Escherichia coli*, are closely related to *Shigella*, showing remarkable phenotypic and genotypic similarities. However, the disease induced by EIEC is generally less severe than that induced by *Shigella* spp.

**Objectives**

EIEC express much less *icsB* than *S. flexneri*, our hypothesis is that EIEC are being efficiently recognized and eliminated by the host cell autophagic process. Moreover, we examined the role of *icsB* in this process.

**Methods**

We generate an *icsB* EIEC mutant by pGEM-T easy Vector System, pJP5603 plasmid and DH5- $\alpha$ pir system. The EIEC $\Delta$ *icsB* was confirmed by RT-PCR. HeLa cells were challenged with wild type EIEC and EIEC $\Delta$ *icsB* for different time points. The delipidation of LC3B was analyzed by Western Blot. Bafilomycin was used as a positive autophagy control.

**Conclusions**

Differently from *Shigella*, EIEC induce autophagy in HeLa cells and this process seems to be independently of *IcsB*. Our results suggest that other virulence factors than *IcsB* are involved in the autophagic process induced by EIEC and that *IcsB* seems to not be a mechanism of EIEC camouflage against autophagic recognition. Additionally, the activated autophagic process could be involved with the slightest spread of EIEC in the host cell, providing a better control of infection.

**SECRETORY PROSTATE APOPTOSIS RESPONSE-4 MIGHT REGULATE  
INTRACELLULAR SURVIVAL OF MYCOBACTERIA**

J.Y. Han<sup>1</sup>, Y.J. Lim<sup>1</sup>, J.A. Choi<sup>1</sup>, J.H. Lee<sup>1</sup>, S.H. Jo<sup>1</sup>, C.H. Song<sup>1</sup>

<sup>1</sup>Microbiology, Chungnam National University School of Medicine, Daejeon, Korea

**Background**

Regulation of apoptosis has become one of the hot topics in mycobacterial infection. Recently, prostate apoptosis response-4 (Par-4), a tumor suppressor protein, is known to cause apoptosis in prostate cancer cells. Par-4 also participates in apoptotic pathway via interaction with glucose regulated protein 78 (GRP 78), which is activated by endoplasmic reticulum (ER) stress under stressful situation. Previously, we reported that ER stress-induced apoptosis plays a critical role as a host defense mechanism against *Mycobacterium tuberculosis* (Mtb). In this study, we investigated the role of Par-4 during mycobacterial infection.

**Objectives**

The aim of this study was to investigate the effect of Par-4 expression on mycobacterial apoptosis in macrophages.

**Methods**

We showed that mycobacterial infection induced expression of Par-4 and GRP78. Additionally in this study, strong interaction between Par-4 and GRP78 was shown at Mtb-infected macrophage surface through quantitative colocalization analysis. To determine if apoptosis could be initiated by GRP78 and Par-4 complex, we used siRNA for Par-4 before Mtb infection. Annexin V staining was used to identify apoptotic cell death. As expected, siPar-4 decreased apoptotic cell death induced by mycobacterial infection.

**Conclusions**

We found that Mtb infection activated Par-4 expression as well as ER stress induction. The interaction of extracellular Par-4 and cell surface GRP78 led to apoptosis via activation of caspase-8/caspase-3 pathway. The intracellular survival of

Mtb H37Ra was increased in Par-4 siRNA treated macrophages. These data suggested that Par-4 plays a crucial role in the intracellular survival of mycobacteria.

## **INITIAL MICROBIAL COMMUNITY INFLUENCES GUT MICROBIOTA COMMUNITY STRUCTURE EVEN AFTER LONG-TERM DIETARY INTERVENTION**

H. Barron Pastor<sup>1</sup>, D.M. Gordon<sup>1</sup>

<sup>1</sup>*Research School of Biology. College of Medicine Biology and Environment,  
Australian National University, Canberra, Australia*

### **Background**

Short and long term dietary interventions influences the structure and activity of gut bacterial communities. Recent literature suggests that the impact of dietary changes depends on microbial community structure at the time dietary changes are initiated.

### **Objectives**

Investigate the effects of long-term dietary fibre intervention on the gut microbiota of rats from the same and different litters.

### **Methods**

Forty-five, 21-day old female rats from six different litters were fed one of three diets: 5% fibre, 26% fibre (insoluble-cellulose) and a diet consisting of 50% of a basal diet and 50% cooked red kidney beans (rich in soluble-fibre). Each animal in a litter was randomly assigned to one of the three diets. Gut microbiota composition was determined before and after 14-weeks of treatment. Microbial communities were characterized using 16s amplicon sequencing. Taxonomic affiliations were determined using Mothur and SILVA bacteria database.

At the start of the experiment the microbial communities present in a rat varied with a rat's litter membership. After 14 weeks on the experimental diets an animal's microbial community composition significantly varied with diet, but significant litter membership effects remained. After diets treatments fibre, short-chain fatty acid, nitrogen and carbon composition of the faeces depended on an animals litter membership and diet.

### **Conclusions**

The results suggest that efforts to enhance the health of humans and other animals through the use of prebiotics may have limited success in general due to among individual differences in the composition of their microbiotas and differences in how these microbiotas respond to dietary manipulation.

Soverini<sup>2</sup>, A.N. Crittenden<sup>4</sup>, A.G. Henry<sup>3</sup>, G. De Bellis<sup>1</sup>, P. Brigid<sup>2</sup>

<sup>1</sup>*Institute of Biomedical Technologies, Italian National Research Council, Segrate (MI), Italy*

<sup>2</sup>*Department of Pharmacy and Biotechnology, University of Bologna, Bologna, Italy*

<sup>3</sup>*Plant Foods in Hominin Dietary Ecology Research Group, Max Planck Institute for Evolutionary Anthropology, Leipzig, Germany*

<sup>4</sup>*Metabolism Anthropometry and Nutrition Laboratory Department of Anthropology, University of Nevada, Bologna, USA*

### **Background**

In a recently paper (Schnorr et al., 2014), we provided the first characterization of the fecal microbiota for a community of human hunter-gatherers, the Hadza of Tanzania. Our data suggested a new mutualistic layout for the gut microbiome (GM), with an enrichment in opportunistic bacteria and a depletion in health-promoting *Bifidobacterium*.

### **Objectives**

To obtain a deeper understanding of the GM-host mutualism in the Hadza, we explored the enterocyte-associated microbiome (EAM), whose layout of the EAM can inform about the functional influence on the host epithelium and other cell types in the mucosa, with critical implications for the maintenance of immune homeostasis. Microorganisms that directly interact with the enterocyte surface have a primary role in the microbiota-host cross-talk.

### **Methods**

By means of a previously developed non-invasive *ex-vivo* minimal model, based on mucus-secreting HT29 cells (Centanni et al., 2013; 2014), we characterized the EAM of 21 Hadza compared to 9 urban living Italians by 16S rRNA barcoded sequencing, and inferred the functional profiles via PICRUST.

### **Conclusions**

Compared to Italians, the Hadza EAM were characterized by a greater amount of adhesive and opportunistic microorganisms, such as Enterobacteriaceae and Pseudomonadaceae, resulting in a functional enrichment in cell motility, signal transduction, interaction and biofilm formation. Our results depict an interesting mutualistic configuration of the intestinal mucosal microbiome in Hadza that is

capable of enhanced microbiota-host cross-talk and interaction at the mucosal surface. These findings stress the importance of a deep microbe-host interaction at the intestinal mucosal interface along the course of human evolution.

<sup>2</sup>*Institute of Biomedical Technologies, Consiglio Nazionale delle Ricerche, Milan, Italy*

<sup>3</sup>*DISAAA - Agriculture Food and Agro-Environmental, University of Pisa, Pisa, Italy*

<sup>4</sup>*Agricultural and Environmental Sciences - Production Land agrienergy, University of Milan, Milan, Italy*

**Background**

The rumen, an heterogeneous microbial community including bacteria, archaea, protozoa and fungi, is a natural habitat that has evolved into an efficient system for lignocellulose degradation. Thanks to this microbiota, ruminants convert the plant materials into digestible compounds, such as volatile fatty acids, their main energetic fuels, and bacterial proteins. The equilibrium of ruminal microbiota is dependent on the diet, which carries fermentation substrates, and the efficiency of ruminal microbiota can be strongly affected by dietary changes.

**Objectives**

The objective of this study was to assess the effects of linseed or hemp seeds diet supplementation on bacterial diversity in the rumen content of goats using the Next Generation Sequencing.

**Methods**

In nine pluriparous Alpine goats fed the same pre-treatment diet for 40 days, ruminal fluid samples were collected, before feeding, using an aesophageal polyethylene probe. After this pre-treatment period the goats were arranged to three dietary treatment groups consisting of control diet (C), control diet supplemented with linseed (L) or hemp (H) seeds. Ninety days later, the same ruminal sample collection procedure was performed. The bacterial DNA was extracted using a protocol described in literature and 16S rRNA gene amplicons on V3-V4 region analyzed by Miseq (Illumina).

## **Conclusions**

In the three dietary treatment groups, bacterial community was dominated by Bacteroidetes and Firmicutes with a high abundance of Prevotellaceae, Porphyromonadaceae and Veillonellaceae and a low presence of Ruminococcaceae and Lachnospiraceae. However, L treatment seemed to affect the bacterial population, reducing the microbial diversity.

**SEQUENCE BASED COMMUNITY ANALYSIS OF POLYMICROBIAL INFECTIONS**

A. Dötsch<sup>1</sup>, S.M. Marten<sup>1</sup>, A. Decker<sup>1</sup>, S. Kirchen<sup>1</sup>, O. Armand<sup>2</sup>, M. Korsch<sup>3</sup>,  
D. Pieper<sup>4</sup>, J. Overhage<sup>1</sup>, U. Obst<sup>1</sup>

<sup>1</sup>*Institute of Functional Interfaces, Karlsruhe Institute of Technology, Eggenstein-Leopoldshafen, Germany*

<sup>2</sup>*Institute of Toxicology and Genetics, Karlsruhe Institute of Technology, Eggenstein-Leopoldshafen, Germany*

<sup>3</sup>*Dental Surgery, Dental Academy for Continuing Professional Development, Karlsruhe, Germany*

<sup>4</sup>*Microbial Interactions and Processes, Helmholtz Centre for Infection Research, Braunschweig, Germany*

**Background**

Many microbial infections involve formation of biofilms containing multiple species. Besides the difficult treatment, the taxonomic and functional characterization of the microbial communities is a major challenge and classic culture-dependent methods often fail to fully characterize the infection.

**Objectives**

Our aim is the development of Next-Generation Sequencing based methods combining analysis of 16S-amplicons with metagenomics to reveal both the taxonomic and functional diversity of infection related microbial communities with a focus on virulence and presence of resistance determinants.

**Methods**

We analyzed samples from chronic lung infections and acute infections of dental implants (peri-implantitis). Taxonomical composition was determined by sequencing barcoded amplicons of the 16S rRNA V1-V2 variable regions using Illumina technology. Sequences were compared with the Ribosome Database Project for the characterization of taxa. Selected samples were also used to isolate whole genomic DNA for metagenomic sequencing using Illumina technology. Sequences were assembled and annotated by bioinformatic gene prediction and alignment to the NCBI non-redundant nucleotide database.

**Conclusions**

The taxonomic composition of the samples both from chronic lung infections and peri-implantitis revealed complex communities in both settings. The dominant taxa included pathogenic taxa like *Pseudomonas*, *Staphylococcus* and *Streptococcus* in the cystic fibrosis lung infections and several Bacteroidetes like *Tannerella* and *Porphyromonas*, which are commonly described in such infections. Analysis of Metagenomic sequences is ongoing to reveal the functional content of the communities with focus on virulence factors and resistance determinants. Employing metagenomics and amplicon sequencing combines taxonomic accuracy and cost-efficiency with a deep insight in the functional genomic content of microbial communities.

**ANALYSIS OF MICROBIAL DNA SIGNATURES IN THE RODENT NARES AND OLFACTORY BULBS.**

M. Fraszczak<sup>1</sup>, S. Moschos<sup>1</sup>

<sup>1</sup>*Faculty of Science and Technology, University of Westminster, London, United Kingdom*

**Background**

The nose is rich in bacterial species that produce outer membrane vesicles (OMV) known to participate in inter- and intra-species signalling. These structures, however, are highly reminiscent of eukaryotic exosomes and synthetic liposomes: all of these nanostructures involve lipid bilayers containing biomolecules such as DNA, RNA and/or protein. The blood-brain barrier has long scuppered efforts of drug delivery to the brain. Encouragingly, studies have revealed that the brain can be accessed across the olfactory nasal epithelium with biotherapeutics and nanoparticles.

**Objectives**

The main aim was to investigate the hypothesis that 1) the bacterial material is present in the brain of healthy rodents without causing disease and that 2) the possible entry route is via the nasal cavity across the olfactory epithelium. In addition, we analysed the microbial DNA signatures at the phylum and class level.

**Methods**

We first attempted PCR amplification of the V3 hypervariable region of bacterial rRNA genes from the mice and rats brain DNA. Produced amplicons were the subjects of 16S phylogenetic analysis by Ion Torrent Next-Generation Sequencing and RDP analysis.

**Conclusions**

The study proved existence of microbiomes in healthy mammalian brains. The comparison of the microbial signatures indicated that at least some of the bacterial DNA is common at both tissue loci, in support of the precept that nasal bacteria or their products might enter the brain through the olfactory epithelium. In addition, there is some similarity of the bacterial species between mice and rats, though some differences were down to host-species intricacies.

**(Human) microbiome**

**METAGENOMIC CHANGES IN THE GUT OF PROTEIN ENERGY MALNUTRITION (PEM) MURINE MODEL**

S. Garg<sup>1</sup>, R.K. Malik<sup>1</sup>, T.P. Singh<sup>1</sup>

<sup>1</sup>DAIRY MICROBIOLOGY, NATIONAL DAIRY RESEARCH INSTITUTE, KARNAL, India

**Background**

Protein energy malnutrition is a potentially fatal body depletion disorder. The catastrophic effects of malnutrition include diarrhoea, malabsorption, increased intestinal permeability and alleviated immune response, thereby aggravating other pathological conditions and contribute to the global disease burden. Since effective treatment for malnutrition is lacking, therefore, metagenomic procedures allow to access the complex cross-talk between the gut and its microbial flora and understand how a different community composition affects various states of human health.

**Objectives**

The aim of the study is to develop protein energy malnourished (PEM) mice model and to evaluate the various changes in the body and organ weight, histological changes and the total protein content as compared to control. Moreover, a metagenomic approach has been employed for analysing the differences between gut microbial communities obtained from malnourished and apparently healthy mice.

**Methods**

Twelve mice were assigned to two groups (6 each/group) and fed either a malnourished (protein=2%, energy=295.2 calories) or a normal (protein=16%, energy=397.2 calories) diet. Body weight was taken till four weeks after which they were sacrificed. Weight of the visceral organs weight and their histological parameters were analysed. Faecal samples were further analysed for the differences in microbial communities between the two groups through RT-PCR. Serum samples stored under refrigerated conditions (-20°C) were also analysed for total protein content between both the groups.

**Conclusions**

The present study reveals the development of PEM model by analysing various morphological, anatomical and histological parameters. Moreover, it characterizes the microbial community resident in the gut of malnourished mice as compared to control.

Austria*

*<sup>2</sup>Sistan Branch, Iranian Fisheries Organization, Zahak, Iran*

*<sup>3</sup>(BOKU) University of Natural Resources and Life Science,  
Department of Food Science and Technology, Vienna, Austria*

**Background**

As in mammals, studies on the intestinal microbiota of fish have revealed that the bacterial community may influence growth, feed conversion, epithelial development, and immunity of the host.

**Objectives**

This study aims at applying 454 pyrosequencing approach to study the autochthonous and allochthonous-associated microbiota from snow trout.

**Methods**

In total, 32 genomic DNA samples were obtained and then Roche 454 pyrosequencing was applied to the pooled set of 16S rRNA gene amplicons. Sequence data were prefiltered and analyzed with the Quantitative Insights Into Microbial Ecology (QIIME) v 1.8.0 pipeline using default parameters.

**Conclusions**

From our analyses, distinct microbial communities were detected between the snow trout gut-associated and intestinal content-associated microbiota, as has also been observed in human, pig, mice and alligators. According to the results Firmicutes phylum members composed the prominent phyla of the mucosa-associated microbiota regardless of the fish gender. However, in luminal-associated microbiota Fusobacteria phylum group made up the most dominant group in intestinal content of male and female fish. This suggests that the abundance and diversity of bacterial populations in gut mucus is, in general, quite different from the microbiota in gut contents, indicating that some microbial species poorly colonise gut mucosa layer. Many of these bacteria might be of high physiological relevance for snow trout as these groups have been implicated in vitamin production, nitrogen cycling and carbohydrate fermentation.

**DETECTION OF SAPOVIRUS GV.2 BY THE NEXT GENERATION SEQUENCER IN THE STOOL SPECIMENS OF PATIENTS OF GASTROENTERITIS OUTBREAK FROM WHICH PATHOGEN HAD NOT BEEN IDENTIFIED**

N. Inasaki<sup>1</sup>, M. Nagoya<sup>1</sup>, M. Itamochi<sup>1</sup>, I. Shima<sup>1</sup>, M. Obuchi<sup>1</sup>, R. Inahata<sup>1</sup>, S. Hasegawa<sup>1</sup>, M. Kuroda<sup>2</sup>, T. Sata<sup>1</sup>, T. Takizawa<sup>1</sup>

<sup>1</sup>Department of Virology, Toyama Institute of Health, Imizu-city Toyama, Japan

<sup>2</sup>Pathogen genomic center, National Institute of Infectious Diseases, Shinjuku-ku Tokyo, Japan

**Background**

Causative pathogens have not been identified by ordinal examinations in some sporadic and outbreak cases of gastroenteritis received at Toyama Institute of Health. In contrast, some pathogens have been identified by metagenomic analysis using the next-generation sequencer (NGS).

**Objectives**

In this study, pathogens were searched by NGS in one outbreak of gastroenteritis from which pathogen has not been identified by conventional PCR analysis.

**Methods**

RNA-seq libraries were constructed from six specimens collected in the outbreak occurred in 3 facilities of health center for the elderly in April 2013, and were analyzed by MiSeq sequencer (Illumina).

**Conclusions**

About 20,000-50,000 reads were obtained in each specimen by NGS analysis, and 2 to 6 reads of nucleotide sequence of sapovirus (SaV) were identified from 3 specimens. These reads agreed with the part of the sequence of sapovirus Hu/Nagoya/NGY-1/2012/JPN (SaV GV.2) reported firstly in the food-borne gastroenteritis (Nagoya City in 2012) with 93-99% identity. Since multiple sequences of SaV were detected from the same specimen, the virus was suspected to be causative agent. Specific primers for SaV GV.2 were generated and PCR was performed. Products were obtained in all six samples by PCR, and their sequences

were revealed to be 99.8 % identity with that of SaV GV.2. Therefore, SaV GV.2 was concluded to be the causative agent of the present case.

Pathogens that are not able to be detected by conventional primers because of low homology may be identified by metagenomics analysis that is independent on specific primers as in this case.

<sup>1</sup>Microbiology (Molecular Biology), University of León, Leon, Spain

<sup>2</sup>Gastroenterology, Hospital de León, Leon, Spain

<sup>3</sup>Immunology, Hospital de León, Leon, Spain

<sup>4</sup>Genetic, University of León, Leon, Spain

**Background**

Celiac disease (CD) is a chronic inflammatory disorder of the small intestine that presents only in a fraction of genetically predisposed individuals following gluten consumption. Recently, several studies have suggested that abnormalities in the small intestinal microbiota might be involved in the development or the pathogenesis of CD.

**Objectives**

The objective of this study was to characterize the specific composition of the duodenal microbiota of untreated CD patients and non-CD controls without mucosa damage in order to identify possible differences in bacterial communities in the upper small intestine.

**Methods**

Intestinal bacterial communities were identified by pyrosequencing of 16S ribosomal DNA extracted from duodenal biopsies. The study group included 9 untreated CD patients and 9 non-CD controls without duodenal mucosal atrophy.

**Conclusions**

Analysis of a total of 180,825 reads of the 16S rDNA showed that the majority of them were classified within two phyla: *Firmicutes* and *Proteobacteria*. Bacterial richness and diversity was higher in non-CD controls than in untreated CD patients. The principal coordinates analysis revealed that bacterial communities of non-CD controls and untreated CD patients were dispersed without forming a clear group according to the presence or absence of the CD. There is no characteristic pattern of bacterial communities associated to untreated CD patients. There are not differences in any bacterial group community frequencies in the upper small intestine between untreated CD patients and non-CD controls.

**(Human) microbiome**

**METAGENOMIC ANALYSIS OF MICROBIOTA IN THE SEMEN OF PROSTATITIS PATIENTS: MOLECULAR APPROACHES TO ASSESS THE DIVERSITY OF MICROBIAL COMMUNITIES**

S.R. Kang<sup>1</sup>, S.S. Lee<sup>2</sup>

<sup>1</sup>Department of Bio-engineering, Kyonggi University, Suwon, Korea

<sup>2</sup>Department of Life Science, Kyonggi University, Suwon, Korea

Background

Prostatitis is one of the most common urological diseases in men and accompanied by bacterial infection in the prostate gland which occurs in 5-10% of prostatitis patients and also, frequently causes recurrent urinary tract infection. Urogenital health and diseases rely on the interaction between the host and the urogenital microbial community.

Pyrosequencing a next generation sequencing (NGS) technologies allow us to characterize microbial communities using bacterial 16S rRNA sequences with high magnitude faster than previous Sanger dideoxy chain-termination method. Therefore, the aim of this study was to identify specific microbial descents that may play crucial roles in the development of prostatitis and to examine whether the presence or abundance of these bacterial changes in semen of prostatitis patients.

Material and Methods

Semen samples were collected from prostatitis patients and extracted genomic DNA for pyrosequencing by using DNA extraction kit.

Results and Discussion

In this study, some abundant pathogenic genus, such as *Anoxybacillus*, *Staphylococcus*, *Corynebacterium*, *Pseudogluconobacter* and *Enterococcus* in the prostatitis sample were found by using the pyrosequencing techniques.

In this study, in case of normal control, *Streptococcus* and *Corynebacterium* were abundance to 33.5% and 21.2%. On the other hand, the most abundant genera in semen of prostatitis patient were *Enterococcus* (20.7%), *Pseudogluconobacter* (16.2%) and *Anoxybacillus* (14.3%). These data provided the comprehensive report on bacterial communities between normal and prostatitis patients and also, it is concluded that prostatitis is related to substantial alteration in the composition and representation of the urogenital bacterial biota.

This identified variability in community membership and structure has important implications for understanding the etiology of prostatitis, for developing diagnostic tools and for treatment.

**UNDERSTANDING OF HUMAN DANDRUFF SCALP THROUGH COMPARATIVE ANALYSIS BETWEEN MICROBIOME AND MYCOBIOME**

J. Kim<sup>1</sup>, W. Choi<sup>1</sup>, W. Kim<sup>1</sup>

<sup>1</sup>Medical microbiology, Chung-Ang University, Seoul, Korea

**Background**

Dandruff is a global common problem, up to 50% of both genders suffer from dandruff. However, although bacteria and fungi associated with dandruff are known, understanding the etiology of dandruff is incomplete.

**Objectives**

Correlation of the bacterial and fungal communities with dandruff is needed because the human skin is associated with many microorganisms with potential for both beneficial and detrimental interactions.

**Methods**

For all cases, samples from normal scalps and severe dandruff patients were collected and analyzed under protocols approved by Chung-Ang University College of Medicine IRB (Protocol #2012-02-01). From the collected samples, we amplified variable regions V1-V3 of the 16S rRNA gene (bacteria) and the D1/D2 region of the 26S rRNA gene (fungi) using universal primers and GS-FLX pyrosequencing.

**Conclusions**

Firmicutes were the most dominant in dandruff patients and showed an increase from 5.2% in cases defined as normal scalps to 91.0% in severe dandruff patients. Whereas, Proteobacteria decreased from 60.1% in the normal scalp to 6.2% in dandruff patients. Similarly fungi of the phylum Basidiomycota were associated with the normal scalp, decreasing from 66.6% to 24.7% in severe dandruff. In the Firmicutes *Staphylococcus* spp. were dominant in the dandruff scalp. In contrast, *Malassezia* spp. in the Basidiomycota were the most abundant fungus in the healthy scalp. This switch from *Malassezia* to *Staphylococcus* provides new comparative information on the microbiomes of the normal scalp and patients with exacerbated dandruff. Consequently, our results can be expected to lead to improved diagnosis and treatment.

**GENOMIC ANALYSIS OF NOVEL CHITINOLYTIC SUBSPECIES OF  
CLOSTRIDIUM SARTAGOFORME FROM BUFFALO RUMEN REVEALS ITS  
IMPORTANT ROLE IN VOLATILE FATTY ACID PRODUCTION**

R. Kothari<sup>1</sup>, N. Nathani<sup>1</sup>, S. Duggirala<sup>2</sup>, C. Joshi<sup>3</sup>

<sup>1</sup>Department of Biosciences, Saurashtra University, Rajkot, India

<sup>2</sup>Department of Microbiology, Gujarat Vidyapith, Sadra, India

<sup>3</sup>Department of Animal Biotechnology, Anand Agricultural University, Anand, India

**Background**

The rumen of herbivores is an open fermentation chamber for digestion of complex plantbiomass by highly efficient bacteria

**Objectives**

Isolation of anaerobic rumen microbes from buffalo and its pheno-genotypic analysis. Correlate the genomic analysis with metagenome data for implication of the isolate's role in rumen

**Methods**

A strain of *Clostridium sartagoforme* species was isolated from buffalo rumen, involved in cellulose and chitin degradation. The isolate was cultured between 37°C and 42°C temperature with an optimum pH of 7.5 in Hungate's medium supplemented with cellulose. Whole genome sequencing was performed using ion torrent PGM. Taxonomy study using local BLAST, showed highest phylogenetic relation with *Clostridium sartagoforme* DSM 1292 strain based on comparison of the 16S rDNA sequences. Comparison of sequences coding for housekeeping genes phosphoglycerate kinase and gyrase B confirmed its taxonomic novelty within the *Clostridium* genus. Biochemical assessment of strain's fermentation ability using AN-Biolog plate revealedthat the strain utilized more than 30 different metabolite precursors. Pathway analysis make known the organism to be highly active in the production of volatile fatty acids (VFAs).

**Conclusions**

The isolate represents a new subspecies, for which the name is proposed *Clostridium sartagoforme* AAU1 (GenBank Accession:ASRV00000000). Genomic analysis gives an insight about the role of bacteria in determining ruminant host physiology.VFAs produced by the isolate play a prominent role in animal health maintenance by contributing a major proportion of the ruminants' daily energy requirement. A deeper understanding of genes involved and enzymes encoded allow further industrial applications and modulation of the rumen for enhanced farming applications.

**METAGENOMIC ANALYSES REVEAL A CELLULOLYTIC AND FERMENTATIVE LIFESTYLE IN THE GUTS OF EPULOPISCIMUM-REPLETE SURGEONFISHES**

D. NGUGI<sup>1</sup>, S. Miyake<sup>1</sup>, M. Alnajjar<sup>1</sup>, U. Stingl<sup>1</sup>

<sup>1</sup>Red Sea Research Center,

King Abdullah University of Science & Technology (KAUST), Thuwal (Jeddah),  
Saudi Arabia

**Background**

*Epulopiscium fishelsoni*, is a giant bacterium found exclusively in the guts of surgeonfishes. Three years after the publication of an incomplete draft genome of *Epulopiscium* sp. type B from *Naso tonganus*, we still have no clue into the metabolic potential of this hitherto uncultivated symbiont, and more so, the functions of the gut microbiota in reef fishes.

**Objectives**

Hence we were prompted to fill this knowledge gap, and thus provide a foundation for understanding the physiology and ecological roles of their microbiota.

**Methods**

We therefore employed a metagenome-sequencing approach to explore the phylogenetic diversity of *Epulopiscium*, and through binning of assembled metagenomic contigs, also shed insights into their metabolism.

**Conclusions**

Our data shows that distinctive feeding guilds of surgeonfishes harbour different *Epulopiscium*-like phylotypes, and that the low-to-high intestinal abundances of these bacteria correlate with their algal diet types. Metabolic reconstruction of the draft *Epulopiscium*-like genomes from these fishes revealed a capacity to catalyze hemicellulolysis and an anaerobic fermentation lifestyle that produces acetate and lactate. Our data thus provides the first in-depth analysis into their diversity and putative symbiotic role, which in turn illuminates the potential metabolic links shaping the symbiosis between the host and the giant bacteria. We further present more insights from the draft genomes, focusing on the nature of this symbiosis, and its interconnection to the trophic ecology of the fishes.

## ASSESSMENT OF THE EFFECT OF ROUGHAGE DIET ON FUNCTIONAL CAPACITY RELATED WITH THE METABOLISM OF AROMATIC COMPOUND OF BUBALUS BUBALIS (MEHSANI BUFFALO) RUMEN METAGENOME

V. Prajapati<sup>1</sup>, A. Patel<sup>1</sup>, N. Parmar<sup>1</sup>, C. Joshi<sup>1</sup>

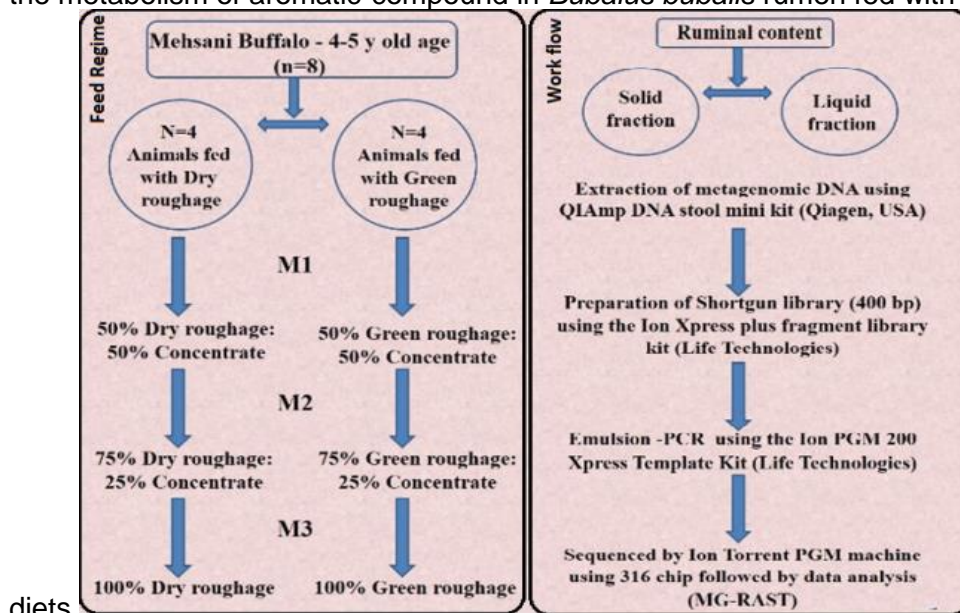

<sup>1</sup>Animal Biotechnology, Anand Agricultural University, Anand, India

### Background

Aromatic compounds comprise one-quarter of the Earth's biomass and are the second most widely distributed class of organic-compounds in nature, next to carbohydrates. In tropical-countries, the buffalo are fed on lignocellulosic agricultural by-products like cereal-straws and tree-foliage. Ruminants digest such plant-materials by microbial-processes. The role of microbiota as reservoir of its unique functional capacity related to the metabolism of aromatic-compound needs to be explored in buffalo rumen.

### Objectives

In the view of above concern, objective of the present study was to account the comparatives profiling of phylogenetic and functional-potential of genes related with the metabolism of aromatic-compound in *Bubalus bubalis* rumen fed with different

diets.

### Methods

The metagenomic analysis of liquid and solid-fraction of the rumen-biomaterial collected from *Bubalus bubalis* was carried out using high-throughput sequencing. The experimental animals received M1 diet for 6 weeks followed by M2 for 6 weeks and

then M3 for subsequent 6weeks. On the last-day of each experimental feeding period, rumen-samples were collected 3h post feeding using stomach tube.

## **Conclusions**

The work presented here describes composition of overall functional-capacity related with the genes for metabolism of aromatic-compound and responsible taxonomic-communities of buffalo rumen-ecosystem. The higher %abundance was found to be related with genes involve in peripheral-pathway for catabolism of aromatic-compound in all treatment-groups. The taxonomic analysis of metagenomic reads indicated that rumen-microbiomes were dominated by Bacteroidetes and Firmicutes phyla in the all treatments-groups. The information obtained from this research will open new-horizons towards a full understanding of functional-genes related with metabolism of aromatic-compound and metabolic-capabilities of complex-compound degrading rumen-microorganisms.

<sup>3</sup>Department of Animal Sciences, University of Vermont, Burlington, USA

<sup>4</sup>School of Animal and Comparative Biomedical Sciences, The University of Arizona, Tucson, USA

**Background**

Reindeer are large Holarctic herbivores, which rely on a consortium of anaerobic microorganisms in the rumen and hindgut to digest plant cell wall carbohydrates. Reindeer may include a large fraction of lichens in their winter diet. Lichens are high in phenolic secondary compounds, which may affect the reindeer gut microbiome, and possibly alter the output of methane. Methane is produced by methanogenic Archaea mainly from CO<sub>2</sub> and hydrogen.

**Objectives**

In this project we examined the effect of lichens on the reindeer rumen and hindgut methanogenic Archaea.

**Methods**

Rumen and cecum samples were collected from two groups of Norwegian reindeer (*Rangifer tarandus tarandus*), one group (n=4) fed lichens and one fed a standard pelleted reindeer feed (n=3). The diversity of methanogens was assessed using 454 pyrosequencing. Real-time PCR experiments were performed to estimate the population densities. All animals were sacrificed in accordance with Norwegian regulations, Sections 9 and 10 in the Norwegian Animal Welfare Act.

**Conclusions**

Densities of methanogens and protozoa were higher in the cecum of lichen-fed reindeers but no differences were found in rumen samples. *Methanobrevibacter* (≥ 97% similarity) was the major genus of Archaea in all the samples, with *M. thaueri* as the dominant species in all reindeers fed lichens (>60% on average). Remarkably, *M. ruminantium* suffered a significant increase (up to 23,8%) with a lichen-based diet in both sampling sites. In conclusion, the intake of lichens affected to some extent the microbial diversity and density of the microbiome housed in the rumen and cecum of reindeer.

<sup>2</sup>*ITB-Segrate, CNR, Milan, Italy*

**Background**

Drinking water quality is a public health concern worldwide. Growing evidences depict drinking water as a complex matrix, in which a wide diversity of microorganisms interact in a dynamic network. Recent studies reveal that drinking water treatment process can affect the microbiome structure. Moreover the occurrence of antibiotic resistance genes in water is becoming an issue of great interest as the mobile resistome can easily spread among species. Molecular techniques can give a deeper knowledge, going beyond the limit of culture-dependent methods.

**Objectives**

In this study we evaluated and standardized a new pipeline for microorganisms concentration, DNA extraction and amplification, suitable for molecular analysis and optimized for High-Throughput Sequencing (HTS) approaches.

**Methods**

We collected samples in a water treatment plant in Milan (Italy), at different steps of the potabilization processes, from the aquifer to the tap. We analyzed the presence and the relative abundance of bacteria and eukaryotic microorganisms across the water treatment plant. Furthermore the presence of specific antibiotic resistance genes was detected and quantified with Real Time PCR, at each step of water treatment process. Since molecular techniques are unable to differentiate between viable and nonviable microorganisms, live/dead ratio was estimated using SYTO9/propidium iodide staining coupled with microscopy visualization. These analyses are integrated in a broader study characterizing microbiome structure variability using HTS techniques, in order to better understand this complex ecosystem.

**Conclusions**

The results agree with those obtained in the few recent studies published till now and can help to unravel the dynamics underlying water microbiome changes.

<sup>6</sup>Centro di Ricerca per lo studio delle relazioni tra Pianta e Suolo,  
Consiglio per la Sperimentazione e la Ricerca in Agricoltura, Rome, Italy

**Background**

Phototrophic and heterotrophic bacteria have been found directly inside halite evaporites that formed as bottom-growth crusts in a hyperarid core and inside gypsum minerals. The role of microorganisms in the precipitation of authigenic minerals like carbonates, sulphides and silicates, has been documented by some authors in several natural systems.

**Objectives**

In this study the interface between biological and geochemical components in the surface crust of a saline soil was investigated. The bacterial community structure and diversity as well as the possible role of the photosynthetic microbial community in the formation of the soil crust was evaluated.

**Methods**

A variable pressure scanning electron microscope equipped with energy dispersive X-Ray diffraction analysis was used for geochemical analysis, while pyrosequencing of the V2-V3 16S rRNA gene region was used for characterizing microbial diversity and community structure.

**Conclusions**

The organization and diversity of the microbial taxa was analyzed according to the physical and chemical heterogeneity of that peculiar habitat. Mineral structures made of gypsum and halite were documented as crystallized around the filaments of cyanobacteria. A univocal causal relationship could not be established between the crystallization of gypsum or halite and cyanobacterial or algal metabolism but their compartmentalization respect to the biological mat suggested that the organisms

could have at least a physical control over the distinctive structures produced. The results provided information on the type of distribution of different bacterial and cyanobacterial groups as a function of the biogeochemical interfaces, suggesting also possible forms of microbial interaction.

**METAGENOMIC ANALYSIS OF MICROBIAL AND VIRAL COMMUNITIES WITHIN A FRESHWATER LAKE IN NORTHERN IRELAND**

C. de Leeuwe<sup>1</sup>, T. Skvortsov<sup>1</sup>, J. McGrath<sup>1</sup>, J. Quinn<sup>1</sup>, Y. McElarney<sup>2</sup>, C.C.R. Allen<sup>1</sup>, L.A. Kulakov<sup>1</sup>

<sup>1</sup>*School of Biological Sciences, Queen's University Belfast, Belfast, United Kingdom*

<sup>2</sup>*Newforge, Agri-Food and Biosciences Institute, Belfast, United Kingdom*

**Background**

Bacteriophages are the most abundant biological entities in the biosphere. They influence the evolution and dynamics of microbial populations. Although phage populations were studied extensively for the marine environment only few studies were dedicated to freshwater ecosystems.

**Objectives**

The main objective of this project is to study the phage population in Lough Neagh, the largest freshwater lake in the British Isles and to analyse interaction of these phages with bacterial hosts.

**Methods**

Both total microbial and viral subpopulations were investigated using standard protocols. Isolation of viral fractions was performed by common procedures. Pyrosequencing was used to identify bacterial communities and the dynamics of the bacterial population's changes in Lough Neagh are compared with seasonal variation. Illumina sequencing was used to characterise viral communities in the same environment.

**Conclusions**

16S rRNA analysis detected a diverse range of bacterial phylum in both water and sediment. Proteobacteria, Acidobacteria, Bacteroidetes and Planctomycetes are found in the freshwater samples which are comparable to the sediment samples. The water samples taken from Lough Neagh have bacteria phylum which are not present in the sediment samples such as Chlamydiae. Analysis of viral metagenomes detected the presence of 16S rRNA sequences probably originated from transducing particles. For example Pelagibacteraceae was identified and. this bacterial family is more commonly found in the oceans rather than a freshwater lake. Possibly this may indicate interactions between bacterial species from two different environments. Illumina analysis of viral metagenomes provided a diverse range of information and can be compared to other published metagenomes.

*<sup>2</sup>UMR 1349 Institut de Génétique Environnement et Protection des Plantes - Agro-Campus Ouest - Université de Rennes 1, INRA, Le Rheu, France*

*<sup>3</sup>UMR 1347 Agroécologie Plateforme GenoSol AgroSup - Université de Bourgogne, INRA, Dijon, France*

#### **Background**

The growing need to survey the tremendous microbial diversity in a culture independent manner, has led to the development of molecular methods through sequence profiling of conserved genes, in scientific field like ecology, agronomy, biotechnology, plant, animals or human health. Recently, the improvement of the Illumina MiSeq platform to a 2x300 bases paired-end version made it much more attractive for amplicons sequencing in metagenomics. Nevertheless, the lack of nucleotide diversity at initial sequencing positions due to sequence conservation is problematic on Illumina platforms. Moreover, validated Illumina amplicon sequencing protocols do not support more than 96 samples per run, which underutilized the overall capacity of a sequencing run.

#### **Objectives**

We therefore worked on the development of a standardized and optimized high-multiplexed metagenomic solution for the exploration of complex environments.

#### **Methods**

We developed an integrated solution combining (i) a custom and standardized amplification protocol for library preparation; (ii) a 192 custom single index validation strategy within a single run; (iii) the inclusion of a nucleotide sequence variability at the first sequencing cycles; (iv) an accurate paired-end reads assembly process and (v) a dedicated pipeline for taxonomic affiliation and microbial communities analysis.

#### **Conclusions**

Our high-multiplexing sequencing solution validated within complex metagenomics samples, provided high sequencing accuracy and technical reproducibility with no index biases based on taxonomic distribution analysis. The association of technical and bioinformatical improvements yields substantial cost reductions and provides greater target flexibility to investigate structure as well as functions of microbial communities through 16S rDNA, 18S rDNA, ITS and functional genes profiling.

**Metagenomics in the environment**

## **METAGENOMIC ANALYSIS OF NATURAL MICROBIAL COMMUNITIES IN ELECTRO-ACTIVE MARINE SEDIMENTS**

J. Geelhoed<sup>1</sup>, F. Meysman<sup>1</sup>

<sup>1</sup>*Ecosystem Studies, Royal Netherlands Institute for Sea Research, Yerseke, Netherlands*

### **Background**

In marine sediments, a novel group of filamentous sulfide-oxidizing bacteria has recently been discovered, which induce electrical currents over centimetre-scale distances. These so-called cable bacteria grow from the oxic zone into the sulfidic part of the sediment up to a depth of several centimetres. Cable bacteria use a radically novel microbial metabolism, in which electron donor and electron acceptor reactions are spatially separated: the oxidation of sulfide in anoxic sediment layers is coupled to the reduction of oxygen at the sediment surface. This mechanism is only possible when electrons liberated from sulfide oxidation are transported from cell to cell along the length of the filament to the oxic sediment surface.

### **Objectives**

To identify a marine sediment where cable bacteria are active in situ and to study the sediment microbial community using shotgun metagenomic sequencing.

### **Methods**

Depth profiles of oxygen, sulfide and pH were taken with microsensors and cable bacteria distribution with depth was evaluated using fluorescent in situ hybridisation. Metagenomic analysis was performed for different depths of the sediment: the oxic surface sediment, the suboxic zone where neither oxygen nor sulfide was present, and the deeper sulfidic zone without cable bacteria. Extracted sediment DNA was sequenced using Illumina MiSeq with 300 bp paired end reads.

### **Conclusions**

At the examined North Sea site, microsensor profiles indicated that metabolic activity of cable bacteria dominated the sediment geochemistry. The obtained metagenomic

data provide insight into the microbial community composition and functioning, and possible interactions between cable bacteria and other taxonomic groups.

**Metagenomics in the environment**

## **INFLUENCE OF INOCULA SLUDGE VOLUME INDEX ON ANAEROBIC GRANULATION**

P. Gupta<sup>1</sup>, T.R. Sreekrishnan<sup>1</sup>, Z.A. Shaikh<sup>1</sup>

<sup>1</sup>DEPARTMENT OF BIOCHEMICAL ENGINEERING AND BIOTECHNOLOGY,  
INDIAN INSTITUTE OF TECHNOLOGY DELHI, Delhi, India

### **Background**

Granulation is important for successful start-up of high-rate anaerobic reactors and usually takes long time. The influence of inoculum's Sludge Volume Index (SVI) on granulation in high-rate upflow Hybrid Anaerobic Reactor (HAR) was studied.

### **Objectives**

Understanding of microbial community changes due to variations in SVI will help in providing novel reactor setting up conditions to obtain faster granulation rate in high rate anaerobic reactor.

### **Methods**

Ten HARs were operated with inoculum having different values of SVI (100 to 325), SVI were varied by adding different amount of inoculum (10% to 50% of the reactor volume). The methanogenic and bacterial community structures of anaerobic sludge obtained from these ten HARs were examined using culture-independent techniques like DGGE and qPCR.

### **Conclusions**

Results showed that granulation was achieved in HARs with SVI values ranging from 150-210 or 18% to 27% inoculum of the reactor volume. DGGE identified 17 methanogenic and 22 bacterial operational taxonomic units in the ten reactors' samples. DGGE analyses showed dominance of *Methanosaeta* and *Methanosarcina*-like species in reactors where granules were formed. qPCR analysis also confirmed that granulating reactors were rich in aceticlastic methanogens especially *Methanosaetaceae*. Bacterial rRNA genes obtained from DGGE results, were affiliated to four Orders -*Clostridiales*, *Lactobacillales*, *Actinomycetales* and *Bacteroidales*. But, no significant correlation was observed between granulation and bacterial abundance. The concentration of bacterial 16s rRNA genes was found to be less in granulating than non-granulating systems unlike methanogenic genes. Thus, this study suggests to make conditions favorable for growth of aceticlastic methanogens to decrease granulation time.

<sup>2</sup>Georg-August-Universität Göttingen, Institut für Mikrobiologie und Genetik,  
Göttingen, Germany

<sup>3</sup>Heinrich-Heine-University Düsseldorf, Institute of Bioorganic Chemistry, Düsseldorf,  
Germany

<sup>4</sup>Heinrich-Heine-University Düsseldorf, Institute of Molecular Enzyme Technology,  
Düsseldorf, Germany

### **Background**

Environmental DNA derived from uncultured bacteria has huge potential as a source of novel bioactive molecules as shown by recent screening campaigns of metagenome libraries which revealed a number of novel protein families, extremozymes and secondary metabolites. Before constructing a metagenomic library, the choice of the habitat should be carefully considered because it predefines the types and properties of biocatalysts to be discovered.

### **Objectives**

In this study, we have constructed a metagenomic library in *Escherichia coli* DH10b with DNA isolated from the microbial population of a slaughterhouse drain biofilm. By comparative screening for lipolytic, proteolytic and detergent activities we have identified number of clones producing bioactive molecules.

### **Methods**

By applying a functional screening assay for biosurfactant activity, two haemolytic and surface-active clones (SA343, SA354) were identified. Sequence and structural homology analyses revealed that they contained genes encoding N-acyl amino acid synthases (NAS) located on environmental DNA fragments.

### **Conclusions**

The respective NAS proteins (Nas343 and Nas354) were shown to be responsible for the haemolytic phenotype and the biosurfactant synthesis *in vivo*. The molecular organisation of the NAS domain linked here to a c-di-GMP binding domain has so far not been identified in any other known protein. The produced biosurfactant was purified and identified by NMR spectroscopy as N-myristoyl-tyrosine. Its biophysical properties including the critical micelle concentration and the ability to reduce surface tension were compared with chemically synthesised N-myristoyl-tyrosine and shown to be in a similar range. Interestingly, N-acyltyrosine also showed antibiotic activity against various Gram-negative and Gram-positive bacteria.

**MICROORGANISMS INVOLVED IN CARBON AND NITROGEN CYCLING IN THE ARABIAN SEA OXYGEN MINIMUM ZONE**

C. Lüke<sup>1</sup>, D.R. Speth<sup>1</sup>, M. Kox<sup>1</sup>, L. Villanuava<sup>2</sup>, M.S.M. Jetten<sup>1</sup>

<sup>1</sup>Microbiology, Radboud University, Nijmegen, Netherlands

<sup>2</sup>Division Texel, NIOZ, 't Horntje, Netherlands

**Background**

Oxygen minimum zones (OMZs) play a major role in marine biogeochemical cycling. They are characterized by a high microbial diversity adapted to life along an oxic-anoxic gradient. In particular anammox and/or denitrification are dominant processes in these zones accounting for significant loss of nitrogen from the ocean. However, other processes within the nitrogen and also carbon cycling have not been explored well.

**Objectives**

To get insights into the organisms involved in carbon and nitrogen cycling in the Arabian Sea OMZ, we studied the meta-genomes of filtered ocean water recovered at two different depths, the upper zone (170m deep, PA2) and the central zone (600m, PA5).

**Methods**

We systematically screened for marker genes indicative for key nitrogen and carbon cycling processes by blasting the meta-genomes data against manually curated functional gene databases.

**Conclusions**

Both zones are characterized by a large fraction of alpha, gamma and delta-proteobacteria. In PA5, anammox contributed a significant amount to the overall diversity (about 8%) whereas Thaumarchaea were present in higher numbers in the upper zone (about 9%). The predominance of nitrifying archaea over bacteria could also be confirmed by *amoA* diversity. No bacterial *amoA* was detected in the entire dataset, and only very few sequences related nitrogen fixation were recovered. Furthermore, no canonical methane oxidizers could be found. However, *pmoA* sequences only distantly related to known diversity are present and could be linked to a published single cell genome, indicating the possibility of a cryptic methane cycle in the Arabian sea OMZ.

#### **MICROBIOMES OF THE BUILT ENVIRONMENT ARE ALTERED BY DIFFERENT ROOM MAINTENANCE**

A. Mahnert<sup>1</sup>, C. Moissl-Eichinger<sup>2</sup>, H. Müller<sup>1</sup>, A.J. Probst<sup>3</sup>, R.A. Ortega<sup>1</sup>,  
P.A. Vaishampayan<sup>4</sup>, K.J. Venkateswaran<sup>4</sup>, G. Berg<sup>1</sup>

<sup>1</sup>Graz University of Technology, Institute of Environmental Biotechnology, Graz, Austria

<sup>2</sup>Internal Medicine (BioTechMed), Medical University Graz, Graz, Austria

<sup>3</sup>Lawrence Berkeley National Laboratory, Earth Science Division, Berkeley, USA

<sup>4</sup>Jet Propulsion Laboratory, Biotechnology and Planetary Protection Group, Pasadena, USA

#### **Background**

The excessive removal of microbes from controlled built environments like intensive care units, operation theatres and especially cleanrooms is daily routine. However effects of these stringent maintenance procedures on our surrounding microbiomes in indoor environments are unknown.

#### **Objectives**

Since recent studies showed the enormous potential of the human microbiome towards our health, this study aims to resolve the interactive interference of all microbiomes in the built environment and determines its potential for human well-being indoors<sup>1</sup>.

#### **Methods**

High throughput deep sequencing technologies were applied for shotgun metagenomes and 16S/18S rRNA and ITS gene amplicons of Archaea, Bacteria, Eukaryota and fungi. Viability assays using ATP (adenosine tri-phosphate) and PMA (propidium monoazide) were deployed to identify potential viable microbiomes and supported by qPCR to investigate microbial abundance<sup>2,3</sup>. The biotechnological potential was further characterized by VOC's (volatile organic compounds) assays of culturable indoor bacteria<sup>4</sup>.

#### **Conclusions**

These assays revealed high reduction of viable microbial abundance in cleanrooms<sup>5</sup>, higher similarities of viable microbiomes between controlled and uncontrolled areas compared to the total microbial fraction, distinct profiles of microbial communities from floors, medical devices and workplaces in an intensive care unit, and for all controlled built environments not only an overlap with the human, but also the plant microbiome. Hence plant leaves could be identified as a main source for microbial distribution on the surrounding indoor environment.

The knowledge of certain key species and their ecological key functions in controlled as well as uncontrolled built environments will help to control indoor environments in a more sophisticated way for our health inside buildings in the future.

**ACIDOPHILIC AUTOTROPHS AND HETEROTROPHS FACILITATES SLUDGE STABILISATION WITH SIMULTANEOUS HEAVY METAL LEACHING**

A. Mehrotra<sup>1</sup>, T.R. Sreekrishnan<sup>1</sup>

<sup>1</sup>*Biochemical Engineering and Biotechnology, Indian Institute of Technology Delhi, New Delhi, India*

**Background**

Presence of heavy metals impedes use of sewage sludge as a fertilizer. Simultaneous sludge digestion and metal leaching (SSDML) combines conventionally distinct stages of metal leaching and sludge stabilisation into one, making the process economically attractive. Insights into the microbial community involved could enable further optimization of the process.

**Objectives**

To evaluate the performance of SSDML and understand corresponding microbial (bacterial) community shifts. .

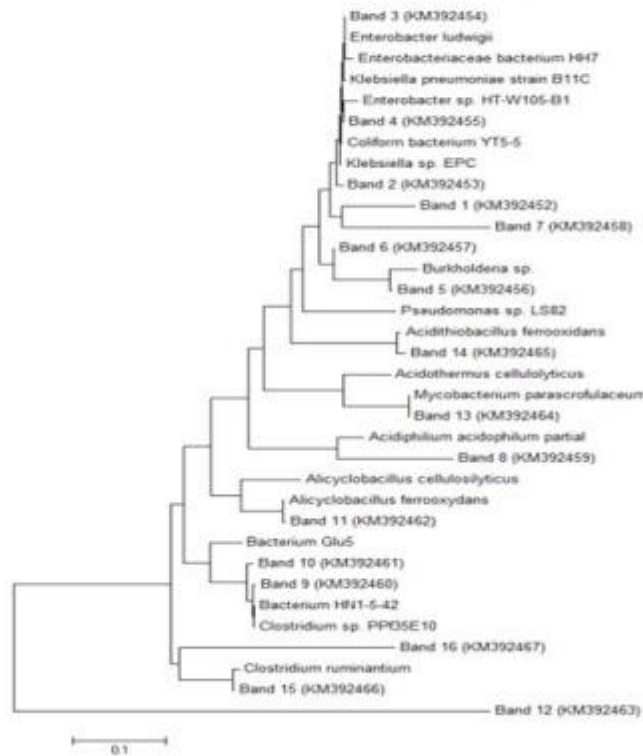

**Figure 1. Bacterial DGGE profile during the process (0, 2, 4, 6, 8, 10, 12 and 15 are the n<sup>th</sup> day of operation of experiment)**

**Figure 2. Unweighted pair group method with arithmetic mean (UPGMA) analysis of DGGE profile in Figure 1**

**Figure 3. Phylogenic relationship of bacterial 16S rRNA sequences obtained from bands eluted from gel shown in Figure 1**

## Methods

Batch study was carried out at 37°C for 15 days after adding sulfur to heavy metal contaminated sludge, with aeration rate of 0.6 vvm. Samples for heavy metals, volatile suspended solids (VSS) analyses and DNA extraction were collected regularly.

## Conclusions

Bio-oxidation of sulfur to  $H_2SO_4$  lowered the pH aiding leaching of metals. Zinc, chromium, cadmium and lead reduced by 86.75%, 64.26%, 79.17% and 69.58% in the dry sludge respectively. Concomitantly, VSS reduction of 49.40 % was obtained making the sludge stable.

*Acidithiobacillus ferrooxidans* and *Acidiphilium acidophilum* were found to be the main bioleaching microorganisms through 16S rDNA PCR-Denaturing Gradient Gel Electrophoresis (DGGE) analysis, in contrast to the commonly reported sulfur-oxidising *Acidithiobacillus thiooxidans*. *Enterobacter*, *Alicyclobacillus cellulolyticus* and *Pseudomonas* were the dominant heterotrophic organisms present across all samples. UPGMA analysis showed a significant microbial shift during the course of operation which could be mainly attributed to the change in pH and solids content.

Thus, after the single stage treatment of SSDML, sludge obtained was stabilised with reduced heavy metal load. PCR-DGGE analysis showed that both heterotrophs and bioleaching microorganisms were present and adapting well according to the dynamic pH.

**QUALITATIVE AND QUANTITATIVE BIAS ESTIMATION OF MICROBIAL COMMUNITY ANALYSIS USING BARCODED 454 FLEX+ METHODOLOGY FOR CLAY CONTAINING GEOLOGICAL SAMPLES**

*H. Moors<sup>1</sup>, K. Wouters<sup>1</sup>, M. Mysara<sup>1</sup>, P. Monsieurs<sup>1</sup>, N. Leys<sup>1</sup>*

*<sup>1</sup>Microbiology, SCK•CEN, Mol, Belgium*

**Background**

High throughput sequencing methodology can be used to determine the composition of environmental microbial communities. Generally, a barcoded PCR amplicon of the omnipresent 16S rDNA gene is used to unravel complex microbial communities. However, several biases and technical difficulties linked to this methodology, may jeopardize the outcome of the community analysis. For instance, it is often difficult to extract DNA out of environmental samples due to interferences caused by the geological matrix. This is especially true for clay containing geological samples. Beside, often containing highly reactive dissolved organic materials, clayey soils are also known for their high sorption capacity of (biological) macromolecules. Therefore, the presence of clay minerals may be responsible for additional biases when analyzing microbial communities of soil or geological samples.

**Objectives**

To quantify the biases, qualitatively and quantitatively, caused by the presence of clay minerals, during analysis of the composition of microbial communities in geological samples, with high throughput barcoded 454 Flex+ DNA sequencing methodology.

**Methods**

Four identical bacterial mockup samples were made, by mixing 18 different soil bacteria. Boom clay was only added to two samples. DNA was extracted, with an identical DNA extraction procedure. The 16S rDNA gene was PCR amplified with four different barcoded 16S<sub>341</sub>-forward primers and one 16S<sub>1492</sub>-reverse primer. The amplicons were sequenced using the 454 Flex+ DNA sequencing methodology. The data were treated with our in house developed bioinformatics pipeline, including the tools, NoDe and CATCh.

**Conclusions**

At the start of the FEMS-symposium 2015 the results and conclusions will be ready to be presented.

**BIOINFORMATICS ALGORITHMS TO GET ACCURATE 16S RRNA HIGH THROUGHPUT SEQUENCING DATA.**

M. Mysara<sup>1</sup>, J. Raes<sup>2</sup>, N. Leys<sup>1</sup>, P. Monsieurs<sup>1</sup>

<sup>1</sup>Unit of Microbiology, SCK•CEN, Mol, Belgium

<sup>2</sup>Bioscience Engineering, Vrije Universiteit Brussel, Brussels, Belgium

**Background**

The revolution in new sequencing technologies has led to an explosion of possible applications, including microbial biodiversity studies via bacterial 16S rRNA amplicon sequencing

**Objectives**

All 16S rRNA amplicon sequencing data suffer from the presence of erroneous sequences: (i) chimeric sequences introduced by the PCR reaction, and (ii) sequencing errors produced by the sequencing platform itself. As such, there is a need for efficient algorithms to remove those erroneous sequences in order to be able to accurately assess the microbial diversity.

**Methods**

First, a machine learning method called CATCh (Combining Algorithms to Track Chimeras) is able to integrate the output of existing chimera detection tools into a new more powerful method, outperforming all existing tools. Second, NoDe (Noise Detector) was introduced as an algorithm to correct 454 pyrosequencing errors, showing a significant improvement in reducing the error rate (reduction of 67 to 75%) and dramatic decrease in computational cost compared to state-of-the-art tools. Similarly, IPED (Illumina Paired End Denoiser) was introduced as first tool in the field for the denoising of MiSeq sequencing data.

**Conclusions**

Integrating both CATCh and NoDe/IPED into the preprocessing pipeline of 16S rRNA amplicon sequencing data significantly increases the reliability of the data, demonstrated by the positive effect on the clustering of the sequencing data in operational taxonomic units (OTUs). When tested on mock communities (MiSeq as well as 454 pyrosequencing platform), the number of OTUs closely approaches the actual number of species present in the mock samples. Both tools are freely available at <http://science.sckcen.be/en/Institutes/EHS/MCB/MIC/Bioinformatics/>.

**MYCOSPHERE EFFECT OF THE PINE MUSHROOM (TRICHOLOMA MATSUTAKE) ON THE DIVERSITY, COMMUNITY STRUCTURE, AND FUNCTIONAL PROFILES OF SOIL MICROBES**

S.Y. Oh<sup>1</sup>, J. Fong<sup>1</sup>, M.S. Park<sup>1</sup>, Y.W. Lim<sup>1</sup>

<sup>1</sup>*School of Biological Sciences, Seoul National University, Seoul, Korea*

**Background**

The mycosphere is a distinct soil environment affected by fungal hyphal activities. Because mycosphere affects microbial activity, it is a valuable source of understanding microbial dynamics in soil ecosystem.

**Objectives**

The main objective of this study is to explore the mycosphere effect of *T. matsutake* by comparing bacterial and fungal diversity, community structure, and functional profiles in different zones of the fairy ring. We expanded on the design of past studies by comparing multiple fairy rings across two geographical locations.

**Methods**

We extracted soil DNA from mycosphere samples in fairy ring of *T. matsutake* and adjacent soil samples.

After processing pyrosequencing data, we conducted metagenomic analysis for microbial diversity, community structure, and functional profiles.

**Conclusions**

Across samples, community was similar within but different between mycosphere and non-mycosphere samples—microbial diversity was lower in the mycosphere compared to non-mycosphere zones. Many ectomycorrhizal fungi were negatively correlated with the presence of *T. matsutake*. Analysis of bacterial functional profiles predicted distinct bacterial activity between zones; in mycosphere samples, xenobiotic biodegradation and metabolism, and amino acid metabolism were high, but carbohydrate metabolism, and glycan biosynthesis and metabolism were low compared to non-mycosphere samples. Overall, similar functional activity of mycosphere zones across fairy rings and geographic locations imply a mycosphere effect of *T. matsutake*, by recruiting mutualistic taxa and excluding antagonistic ones based on the functional trait.

**COMPARATIVE ANALYSIS OF METAGENOMES FROM FILTER UNITS OF FULL-SCALE HYBRID TREATMENT WETLAND**

*K. Oopkaup<sup>1</sup>, T. Ligi<sup>1</sup>, K. Tiirik<sup>1</sup>, M. Truu<sup>1</sup>, H. Nõlvak<sup>1</sup>, U. Mander<sup>1</sup>, J. Truu<sup>1</sup>*

*<sup>1</sup>Department of Geography, University of Tartu, Tartu, Estonia*

**Background**

Treatment wetlands (TW) have become widely used for wastewater treatment over the recent decade for their cost-effective building and maintenance. While physical and chemical pollutant removal mechanisms in TWs are well known, understanding of microbial processes related to pollutant removal in TWs is still low. Metagenomics offers the ability to examine directly the genomic content of microbial communities, complementing taxonomic information with functional capability.

**Objectives**

(1) to characterize microbial communities in vertical and horizontal sub-surface flow (VSSF and HSSF respectively) filter units of a full-scale TW treating wastewater from a schoolhouse for over ten years; (2) evaluate the functional potential of bacterial and archaeal communities.

**Methods**

Water samples, including influent, effluent and intermediate well, together with filter media biofilm from both units were used for shotgun sequencing with Illumina MiSeq system. Metagenomes were assembled into contigs and used for microbial profiling, identifying functional genes and relating them to nitrogen, phosphorus and carbon cycle.

**Conclusions**

Domain distributions showed the dominance of Bacteria (>95%), a small fraction of Eukaryotes (>2%), Archaea (>1%) and Viruses (0.2%). Samples of filter material had similar bacterial dominant phyla, but different distribution of lower taxonomic ranks. Wastewater samples had diverse bacterial community distribution between samples. Over one-third of archaeal sequences belonged to methanogenic species. Nitrogen metabolism in VSSF and HSSF filter units was dominated by ammonia assimilation related genes followed by nitrate and nitrite ammonification, denitrification and nitrogen fixation related genes. Phosphorous metabolism was dominated by phosphate metabolism genes.

#### **HIERBIN - A METHOD FOR DETAILED FUNCTIONAL ANNOTATION AND QUANTIFICATION IN METAGENOMES**

T. Österlund<sup>1</sup>, V. Jonsson<sup>1</sup>, E. Kristiansson<sup>1</sup>

<sup>1</sup>*Mathematical Sciences,*

*University of Gothenburg and Chalmers University of Technology, Gothenburg, Sweden*

#### **Background**

Metagenomics aims for sequencing and identification of DNA from communities of microorganisms in their natural environment. By estimating and comparing gene abundances between samples we can get a picture of the functional role of the metagenome, i.e. which genes and pathways are abundant at different conditions. Methods for functional metagenomics typically rely on identification of functional domains such as PFAMs, TIGRFAMs and COGs. However, this results in a broad classification of gene products since many proteins can be classified into the same functional domain. The human gut gene catalog, for instance, is predicted to contain more than 5 million genes, but the number of PFAM domains is only around 10,000.

#### **Objectives**

We present HierBin, a new method for functional annotation and quantification in metagenomes, giving a more detailed functional description of the metagenome and performing better in identification of changes between conditions.

#### **Methods**

First a supervised classification step is used to identify known functional domains in the data. Secondly, each domain is divided into subdomains using unsupervised clustering based on sequence similarity. Finally the abundance of each subdomain is quantified by mapping the sequence reads to the subdomain sequence and differentially abundant subdomains are identified.

#### **Conclusions**

We show, by evaluating on resampled data, that our method performs better in predicting differential abundant genes than methods using only functional domains for gene prediction and detects differences at higher resolution that would be invisible at lower resolution.

Finally, we apply our method both to metagenomics data from the human gut as well as environmental samples.

**Metagenomics in the environment**

**METAGENOMIC ANALYSIS OF MICROBIAL COMMUNITIES IN RAPID SAND FILTER TREATING GROUNDWATER. COMMUNITY DIVERSITY AND METABOLIC POTENTIAL**

A. Palomo<sup>1</sup>, S. Rasmussen<sup>2</sup>, T. Sicheritz-Ponten<sup>2</sup>, B.F. Smets<sup>1</sup>

<sup>1</sup>Environmental Engineer, Technical University of Denmark, Kgs. Lyngby, Denmark

<sup>2</sup>Center for Biological Sequence Analysis, Technical University of Denmark, Kgs. Lyngby, Denmark

**Background**

Rapid sand filtration is a drinking water production technology widely used in Europe and other countries around the world. This technique allows the removal of ammonia, manganese, ferrous iron, methane, sulfides and other compounds from groundwater by a combination of physical, chemical and biological processes. During many years, it has been recognized that microbial activity plays an important role in these processes.

**Objectives**

Therefore, it is essential to study the microbial composition in these rapid sand filters and how these communities interact and facilitate the removal of pollutants.

**Methods**

In this study, six samples from a rapid sand filter were analyzed through a metagenomic approach. By building a non-redundant gene catalog we identify the microbial diversity and the metabolic pathways occurring in this system.

**Conclusions**

*Nitrospirae* and *Proteobacteria* were the dominant phyla. The functional genetic potential included most of genes related to nitrogen oxidation (specially abundant in the nitrification pathway) and to methane oxidation. Genes involved in different CO<sub>2</sub> fixation pathways were also abundant. Genera typically implicated in manganese oxidation as *Hyphomicrobium* and in iron oxidation as *Gallionella* were also abundant in the catalog. This investigation has so far revealed the main biological processes occurring in these ecosystems. In the next step, we will try to assemble genomes of the most abundant genotypes of the rapid sand filter community.

### **INTRODUCING A COMPLETE METAGENOMICS ANALYSIS PIPELINE, BASED ON AN OPTIMAL COMBINATION OF ILLUMINA SEQUENCING TECHNOLOGY AND AN EASY TO USE ONLINE PLATFORM**

*W. Pirovano<sup>1</sup>, D. Derek Butler<sup>1</sup>, A. Costessi<sup>1</sup>*

<sup>1</sup>NGS, BaseClear, Leiden, Netherlands

#### **Background**

Direct sequencing of metagenomes is commonly implied for bacterial community analysis related to food research, biotechnological processes and clinical diagnostics.

#### **Objectives**

Commonly the taxonomic classification of sequences is based on unique target regions such as the 16S ribosomal gene which includes a number of unique variable regions. In this work we present an overview of a new and comprehensive Metagenomics analysis pipeline that we are using to prepare, sequence and analyze metagenomics samples from a range of environments.

#### **Methods**

In this holistic approach we start with laboratory techniques that take into account and reduce as much as possible the sources of possible bias that can be introduced into metagenomics datasets by laboratory steps like sampling procedures and DNA isolation. We further include both biological and technical controls to continually validate the process.

#### **Conclusions**

The bioinformatic analysis is performed using overlapping paired-end reads which are annotated through the Greengenes database (De Santis *et al.*, 2006). Finally we introduce the 'BaseClear metaGenome Browser' (BmGB)<sup>TM</sup>, <https://metagenomics.baseclear.com>, an online platform in which researchers (with or without any bioinformatics training) can easily interpret the taxonomic composition of hundreds of metagenomes using intuitive interfaces and efficient analyses. The workflow is tested on a number datasets and results are discussed.

**LIMITS TO ROBUSTNESS, REPRODUCIBILITY AND ECOLOGICAL  
CONSISTENCY IN THE DEMARCATION OF OPERATIONAL TAXONOMIC UNITS**

T.S.B. Schmidt<sup>1</sup>, J.F. Matias Rodrigues<sup>1</sup>, C. von Mering<sup>1</sup>

<sup>1</sup>*Institute for Molecular Life Sciences, University of Zurich, Zurich, Switzerland*

**Background**

The demarcation of *Operational Taxonomic Units* (OTUs) from complex sequencing datasets is a key step in large-scale characterizations of microbial communities. However, it remains unclear how well the various proposed OTU clustering algorithms approximate 'true' microbial taxa, and many conceptually distinct approaches continue to be used.

**Objectives**

We explored different aspects of OTU clustering, in particular the robustness, reproducibility and ecological consistency of OTU demarcation.

**Methods**

In a global and comprehensive survey of roughly one million microbial SSU sequences, we objectively quantified biases introduced by several widely employed algorithms.

**Conclusions**

We observed surprising trends in the robustness of sequence clustering to changing parameters, and with regard to the reproducibility of OTU-based findings. Moreover, we explored the ecological consistency of OTUs – based on the assumption that, like true microbial taxa, they should show measurable habitat preferences (niche conservatism). We systematically parsed sequence annotations to obtain broad ecological descriptions of sampling sites. Based on these, we observed that sequence-based microbial OTUs generally showed high levels of ecological consistency. However, different OTU clustering methods resulted in marked differences in the strength of this signal. We found that hierarchical average and complete linkage clustering provided the most robust and reproducible partitions with regard to a wide range of parameters. Moreover, complete linkage clustering provided the ecologically most consistent clusters. Assuming that ecological consistency can serve as an objective external benchmark for cluster quality, we

concluded that hierarchical complete linkage clustering, should be the default choice for OTU clustering.

COPPE Federal University of Rio de Janeiro (UFRJ), Rio de Janeiro, Brazil

<sup>2</sup>Biology, Federal University of Rio de Janeiro, Rio de Janeiro, Brazil

<sup>3</sup>Biology, Instituto de Pesquisas Jardim Botânico do Rio de Janeiro, Rio de Janeiro, Brazil

Background: Turf algae holobionts (host macroalgae plus microbiome) are widespread in coral reefs worldwide. They are also the most abundant benthic structures in the Abrolhos reef Bank (Brazil), with more than 50% benthic coverage. Abrolhos reefs turfs are morphologically diverse regarding color and texture, but their microbial matrix is not well known. Objectives: Our aim was to perform a metagenomic characterization of the prokaryotic microbiome of the different morphologic types of turf algae holobionts from Abrolhos reefs. Methods: We used metagenomic approaches to obtain the whole communities associated with turfs assemblages, collected at different reefs during March and October 2013, totaling 22 samples. Results: Filamentous, non-heterocystous cyanobacteria were the dominant microbial phototrophs of the holobionts. Main macroalgal in the holobiont were red, green and brown seaweeds. 15,27 million reads were generated using Illumina sequencing. Proteobacteria (36.8%, N = 1.564,678), Cyanobacteria (28.8%, N = 1.222,446), and Bacteroidetes (10.2%, N = 434,897 ) were dominant among the turf algae prokaryotic microbiome. Major microbial components of the turf algae holobiont are *Roseobacter* sp., *Silicibacter* sp., *Dinoroseobacter* sp., *Congregibacter* sp., *Maribacter* sp., and Cyanobacteria. Genes belonging to aerobic anoxygenic photosynthesis (AAnP), sulfur metabolism (e.g. S oxidation, and DMSP consumption) and virulence potential (adhesins, fibronectin/fibrinogen-binding protein, type IV pili, superoxide dismutase) were found in the turf algae microbiomes. Conclusion: The complex assemblies of microbial guilds render turf holobionts important competitive advantages allowing them to outcompete other benthic organisms and dominate vast reef areas.

<sup>3</sup>*Laboratory of Soil Science - Department of Geology and Soil Science, Ghent University, Ghent, Belgium*

**Background**

Antarctica is a continent of extremes. Low availability of liquid water and nutrients, extreme low temperatures and high levels of radiation exert high selective pressures on organisms. Consequently, most life forms are microbial. Estimations indicate that as little as 1-3 % of the continental surface represents ice-free regions. Relatively few biological studies focus on terrestrial samples which most often originate from the McMurdo dry valleys that make out the largest contiguous ice-free area. Mountain tops protruding through the ice sheets (*nunataks*) are less frequently studied although they might function as havens and reservoirs for terrestrial organisms. Geological data shows the presence of different kinds of bedrock in the Sør Rondane mountains (Queen Maud Land, East Antarctica). Patches of macroscopic organisms (lichens, mosses and arthropods) are scattered throughout these ice-free islands, indicating a high amount of variability in the presence of organic matter, and hence nutrients for microbial life. Here we present the results of a large scale sampling effort in the eastern Sør Rondane Mountains of such ice-free regions near the Belgian Princess Elisabeth station.

**Objectives**

We examined the composition and distribution of bacterial communities in these refugia, and investigated the possible impact of environmental parameters on these community compositions.

**Methods**

Samples were subjected to both a genetic fingerprinting technique (ARISA) and second generation sequencing (Illumina MiSeq 300PE).

**Conclusions**

Preliminary results indicate an effect of bedrock type and presence of macrobiotic organisms.

Faculdade de Ciências da Nutrição e Alimentação Universidade do Porto. UCIBIO/R  
EQUIMTE. Faculdade de Farmácia Universidade do Porto, Porto, Portugal

**Background**

*Salmonella* 4,[5],12:i:- has become a new epidemic serotype in Europe associated with human infections, being the identification/tracking of its clones crucial to contain their spread.

**Objectives**

We assessed the trends in *S.* 4,[5],12:i:- clones distribution and their association with antibiotic and metal resistance/tolerance genes in Portuguese isolates. Results were also compared with previous data from the last decade (2002-2010).

**Methods**

*S.* 4,[5],12:i:- isolates (n=158), confirmed by PCR (*fliB-fliA/fljB*), from different sources (clinical/food) and regions of Portugal (2010-2014) were analyzed. They were screened for sulfamethoxazole resistance genes (*sul1-sul2-sul3*) and other class 1 integrons genes (*int1*, *qac* and gene cassettes) by PCR. Detection of metal tolerance genes [copper (*pcoD*), silver/copper (*silA*) and mercury (*merA*)] and other antibiotic resistance genes by PCR, susceptibility to 10 antibiotics [ampicillin (A), chloramphenicol (C), gentamicin (G), kanamycin, nalidixic acid, ciprofloxacin, streptomycin (S), sulfamethoxazole (Su), tetracycline (T) and trimethoprim (Tr)] (CLSI/EUCAST) and clonality by PFGE were performed in representative isolates.

## Conclusions

We detected the presence of the 3 clones currently circulating in Europe: i) 'European clone' (75%; *sul2* and absence of *intl1/sul1/qacEdelta1*; mostly ASSuT-*bla*<sub>TEM</sub>-*strA-strB-sul2-tetB* and carrying *pcoD+silA+merA*), which has expanded throughout this study period; ii) 'Spanish clone' [6%; *intl1*; *qacEdelta1+qacH*; mostly AC(G)SSuTTr-*bla*<sub>TEM</sub>-*cmlA-floR-(aac(3)-IV)-aadA-sul1-sul2-sul3-tetA-dfrA12* and carrying *merA-silA*] and iii) 'Southern-European clone' (1%; *intl1*; *qacH*; CSSuTTr-*cmlA-aadA-strA-strB-sul3-tetB-dfrA12*) mostly with similar MDR and/or PFGE-types described since 2002. A marked decreased frequency of Spanish and Southern-European clones was observed contrasting with the expansion of the European clone characterized by ASSuT-phenotype and copper/silver/mercury tolerance genes, which might facilitate adaptation and success of these strains.

<sup>1</sup>Microbiología y Parasitología, University of Seville, Sevilla, Spain

<sup>2</sup>Biología Vegetal y Ecología, University of Seville, Sevilla, Spain

**Background**

As an adjunct to phytoremediation strategies and as part of an effort to make this technology more efficacious, a number of scientists have begun to explore the possibility of using plants and the microbial populations colonizing the rhizosphere.

**Objectives**

A glasshouse experiment using soil from a metal-contaminated estuary was designed to investigate the effect of a native bacterial *consortium*, isolated from *Spartina maritima* rhizosphere and selected owing to their plant growth promoting (PGP) properties and multiresistance to heavy metals, in plant growth and metal accumulation.

**Methods**

Plants of *S. maritima* were randomly assigned to three soil bioaugmentation conditions (without inoculation, one inoculation and repeated inoculations during experimental period) for 30 days. Growth parameters and photosynthetic traits, together with total concentrations of several metals, including As, Cu, Pd and Zn were determined in roots and/or leaves.

**Conclusions**

Bacterial inoculation improved *S. maritima* root growth, through a beneficial effect on its photosynthetic rate ( $A_N$ ) due to its positive impact on functionality of PSII and chlorophyll concentration. Also, bacterial inoculation favoured water use efficiency (WUE) of *S. maritima*, through the increment in  $A_N$ , stomatal conductance and in root-to-shoot ratio. Moreover, this consortium was able to stimulate plant metal uptake specifically in roots, with increases of up to 19% for As, 65% for Cu, 40% for Pb and 29% for Zn. On the basis of these results, bioaugmentation of *S. maritima* with the selected bacterial consortium can be claimed to enhance plant adaptation and metal rhizoaccumulation during marsh restoration programs.

<sup>2</sup>Department of Biosciences Biotechnologies and Biopharmaceutics, University of Bari, Bari, Italy

<sup>3</sup>Department of Biosciences, University of Milan, Milan, Italy

<sup>4</sup>CNR, Institute for Chemical-Physical Processes, Bari, Italy

**Background**

While bacteria belonging to the *Sphingobium* genus are generally known for their capacity to degrade poly-aromatic hydrocarbons, their response to high concentrations of metal ions has been largely disregarded. Only *S. cupriresistens*, a species isolated from a copper mine, has been reported to tolerate high concentrations (0.9 mM) of Cu<sup>2+</sup> [1]. We have recently reported the whole genome sequence of a novel *Sphingobium* strain able to tolerate Ni ions up to 20 mM [2].

**Objectives**

In order to understand the molecular mechanisms by which this strain is able to adapt to high concentrations of Ni ions we are currently investigating its transcriptome profiles by RNA-seq approach.

**Methods**

Sequencing of rRNA-depleted RNA was carried out for independent triplicate cultures in the presence or absence of 10 mM NiCl<sub>2</sub>, using the SureSelect strand-specific RNA library prep kit (Agilent) for Illumina MiSeq multiplex sequencing.

**Conclusions**

Transcriptomic data show the differential expression (fold change  $\geq |2|$ , *p*-adjusted < 0.05) of about one-hundred genes. Most of them are up-regulated in the presence of Ni<sup>2+</sup> and include genes for membrane proteins and metal efflux systems. Gene annotation was further enriched with description of operons and UTRs as identified by the EuGene integrative gene finder tool [3]. The observed metal resistance of this *Sphingobium* strain highlights its possible use for biodegradation of xenobiotic compounds in metal-rich environments.

## **ADAPTABILITY OF TRICHODERMA ASPERELLUM TO HIGH CONCENTRATIONS OF VARIOUS METALS**

S.H. Chen<sup>1</sup>, S.L. Ng<sup>1</sup>, A.S.Y. Ting<sup>1</sup>

<sup>1</sup>*School of Science, Monash University Malaysia, Bandar Sunway, Malaysia*

### **Background**

*Trichoderma asperellum* is a biological agent capable of removing heavy metals from the environment via biosorption and/or bioaccumulation. Most studies investigated the use of dead fungal biomass for metal biosorption. The potentials of using live cells to transform toxic metals into less harmful forms (bioaccumulation) is lesser known.

### **Objectives**

In this study, we explored the adaptability of *T. asperellum* to increasing concentrations (100-6000 ppm) of various heavy metals (Al, Cd, Cr, Cu, Pb and Zn).

### **Methods**

Adaptive tolerance index (TI) of fungus in Potato Dextrose Agar was measured.

### **Conclusions**

The results conveyed bioaccumulation potential of *T. asperellum*. Results revealed that *T. asperellum* has adaptability towards increasing concentrations of Cd (TI: 0.01-0.04), Cr (TI: 0.22-0.28) and Cu (TI: 0.24-0.31) at the beginning of the experiment. Decreasing TI values (from 1.08 to 0.01) with increasing Al, Pb and Zn concentrations indicated poor adaptability. The most tolerable concentration across all metals, except Cu, was 1000 ppm. In fact, *T. asperellum* tolerated up to 6000 ppm Al. Concentrations of 1500-2000 ppm generally exerted inhibitory effects with Cu being most toxic (tolerable up to 300 ppm). The adaptability of *T. asperellum* to high metal concentrations was evident with SEM micrographs showing hyphae growth, in spite of some structural deformities, metal precipitates and particles deposited on the hyphal surface. Nevertheless, in cases where growth was inhibited, the severely deformed hyphae displayed irregular, grooves and rough texture. Our study highlights the potential of live *T. asperellum* cells in removing heavy metals from the environment in a cheap and environmental-friendly manner.

## **RECOVERY OF LITHIUM FOR NATIVE MICROORGANISMS FROM SALAR DE ATACAMA BRINES, CHILE.**

C. Cubillos<sup>1</sup>, C. Dorador<sup>2</sup>, M. Grageda<sup>3</sup>

<sup>1</sup>*Engineering of Mineral Processing Ph.D. program Department of Chemical Engineering., University of Antofagasta, Antofagasta, Chile*

<sup>2</sup>*Microbial Complexity and Functional Ecology Laboratory., University of Antofagasta, Antofagasta, Chile*

<sup>3</sup>*Center for Advanced Research in Lithium and Industrial Minerals., University of Antofagasta, Antofagasta, Chile*

### **Background**

Salar de Atacama (Chile) is the largest basin in Atacama Desert (2900 Km<sup>2</sup>) and is located at 2300 m.a.s.l. This hypersaline system possess an average concentration of lithium as brine of 1500 ppm. Lithium is obtained industrially through the process of solar evaporation ponds, reflecting the conditions present in this Salar, including high UV radiation, high evaporation and low rainfall; however, this process is non-selective and is pollutant. We propose the recovery of lithium from brines based on biosorption using Gram-positive bacteria selectively accumulate lithium

### **Objectives**

The aim of this study was to describe microbial diversity present in brines of Salar de Atacama and to isolate native bacteria with lithium adsorbent potential.

### **Methods**

Natural brines and concentrated lithium brines of Salar de Atacama were characterized. Such brines present hostile conditions for life, including high salt concentrations (0-100 g/L of Na<sup>+</sup>; 190- 450 g/L of Cl<sup>-</sup>; 0.2 -8 % of Li) and pH between 0.9 and 7. Simultaneously, microorganisms from the Salar were grown in a range of mineral mediums with or without organic carbon, and different concentrations of LiCl (0- 300 uM) through which the ability to absorb lithium was determined.

### **Conclusions**

Bacteria and Archaea were detected in both brines. These microorganisms are likely naturally adapted to the differences in concentration of the elements present, especially lithium. Furthermore, bacteria capable of adsorbing lithium after 12 hours were obtained. Analyses of microbial diversity of the brines and development of a process for obtaining lithium by native microorganisms are currently underway.

## **MODELING ARSENITE OXIDATION BY SINORHIZOBIUM SP. M14 IN CHANGING ENVIRONMENTAL CONDITIONS**

K. Debiec<sup>1</sup>, J. Krzysztoforski<sup>2</sup>, A. Skłodowska<sup>1</sup>, L. Drewniak<sup>1</sup>

<sup>1</sup>Laboratory of Environmental Pollution Analysis,

University of Warsaw Faculty of Biology, Warsaw, Poland

<sup>2</sup>Faculty of Chemical and Process Engineering, Warsaw University of Technology, Warsaw, Poland

### **Background**

A complement to the chemical methods of treatment of water contaminated with arsenic are the biological methods i.e. biooxidation. Among the biological methods, technologies using bacteria, which oxidize arsenites, appear to have significant potential. In the literature, many bacterial strains able to oxidize arsenates are described, but most of them are not able to survive in new conditions. These disadvantages can be overcome if we use strains or microflora enriched by the gene pool localized on the plasmid pSinA *Sinorhizobium* sp. M14, carrying genes responsible for arsenic metabolism.

### **Objectives**

The aims of this study were to (i) investigate the impact of biotic and abiotic factors, simulating the natural environment, on the growth kinetics and (ii) develop a kinetic model of arsenite oxidation by *Sinorhizobium* sp. M14.

### **Methods**

The effect of different factors on arsenite biooxidation (i.e. start OD, substrate concentration, mixture of arsenic compounds, temperature and pH) on the efficiency of oxidation of arsenites and the changes of physiological condition of the studied strains was investigated. Cultures were grown on MSM supplemented with 0,04% yeast extract. As speciation samples were analyzed by HPLC/ESI MS, while the amount of biomass was monitored by OD/CFU determination. Based on the collected data, a kinetic model of the process was developed.

### **Conclusions**

Culture of microorganisms in different concentrations of As (1;2,5;5 ppm), in mixture of arsenic compounds -As(III)/As(V) (2,5ppm/2,5ppm; 1ppm/4ppm), in different start OD (0,01;0,025;0,06;0,08;0,1;0,15), in various pH (4;6;7,5;10) and in different temperatures (10;16;22;30°C) allowed to develop a model of kinetics arsenite oxidation by *Sinorhizobium* sp. M14.

## **INVESTIGATIONS ON MULTIMETAL UPTAKE IN THE PRESENCE OF PESTICIDE BY FUNGAL ISOLATE**

P. DEY<sup>1</sup>, A. Malik<sup>1</sup>, D.K. Singh<sup>2</sup>, M. Bergen<sup>3</sup>, N. Jehmlich<sup>4</sup>

<sup>1</sup>Centre for Rural Development & Technology, Indian Institute of Technology Delhi, NEW DELHI, India

<sup>2</sup>Zoology, University of Delhi, NEW DELHI, India

<sup>3</sup>Proteomics & Metabolomics, Helmholtz-Centre for Environmental Research - UFZ, Leipzig, Germany

<sup>4</sup>Proteomics, Helmholtz-Centre for Environmental Research - UFZ, Leipzig, Germany

### **Background**

Wastewaters are often contaminated with complex cocktail of pollutants, out of which heavy metals and pesticides pose significant health risks. However, majority of the researches focus on bioremediation of individual metals or pesticides in isolation.

### **Objectives**

Therefore, efforts are needed to obtain microbial strains which can simultaneously handle multiple pollutants.

### **Methods**

Here a newly isolated fungal strain was assessed for its multimetal and pesticide uptake potential in the composite salts medium using glucose and lindane pesticide as the carbon and energy sources. This strain was able to grow in the presence of 1% glucose, 30 mg/L lindane and 30 mg/L multimetal (5 mg/L each of Cd<sup>2+</sup>, Cr<sup>6+</sup>, Cu<sup>2+</sup>, Ni<sup>2+</sup>, Pb<sup>2+</sup> and Zn<sup>2+</sup>) and could degrade maximum amount of lindane to 1.92 ± 0.01 mg/L in about 72 h. The cube root growth kinetic constant (k) of the strain was obtained as 0.0211 g<sup>1/3</sup> l<sup>-1/3</sup> h<sup>-1</sup> in batch study. However, the presence of lindane caused an inhibition effect in the uptake of heavy metals and thus only Pb and Zn were brought down below the permissible mandates for irrigation. The results indicate that the growth kinetics and pollutant uptake is affected by the nature of contaminant matrix. More studies towards the elucidation of mechanisms of metal removal by the fungus in presence and absence of pesticide by various spectroscopic and microscopic techniques such as SEM, TEM-EDX, FTIR, XRD and XPS have been conducted.

### **Conclusions**

These results reveal the inherent potential of this fungal strain to remove multimetals in the presence of pesticide from contaminated wastewater.

**SEARCH FOR BACTERIA IN A MEDIEVAL ARCHEOLOGICAL SITE IN VERDUN (FRANCE) AND ISOLATION OF CUPRIAVIDUS NECATOR B9, A NEW METAL RESISTANT STRAIN**

D. Gillan<sup>1</sup>, N. Thomas<sup>2</sup>, L. Vermard<sup>3</sup>, A. Provoost<sup>4</sup>, G. Billon<sup>5</sup>, M. Mergeay<sup>4</sup>, R. Wattiez<sup>6</sup>

<sup>1</sup>Proteomics & Microbiology, University of Mons, Mons, Belgium

<sup>2</sup>Inrap-UMR 8589 Lamop, Université Paris 1 Panthéon-Sorbonne-CNRS, Paris, France

<sup>3</sup>INRAP, INRAP, Paris, France

<sup>4</sup>Unit of Microbiology, SCK-CEN, Mol, Belgium

<sup>5</sup>Géosystèmes, Université de Lille 1, Villeneuve d'Ascq, France

<sup>6</sup>Proteomics & Microbiology, Mons University, Mons, Belgium

**Background**

Remains of a well-preserved medieval foundry were excavated by archaeologists in 2013 in Verdun (France). Three to four ancient workshops specialized in brass and copper alloys were found with an activity between 13<sup>th</sup> to 16<sup>th</sup> c. Levels of Cu, Zn and Pb reached 20 000, 7000 and 6000 mg kg<sup>-1</sup> (dw), respectively, in several soil horizons.

**Objectives**

The objective was to examine the microbial community in this contaminated site.

**Methods**

A total of 8–22 10<sup>6</sup> reads were obtained by shotgun metagenomics in each horizon (length : ± 220 pb). Bioinformatic analyses suggest the presence of very complex bacterial communities dominated by Proteobacteria. Using selective media three *Cupriavidus necator/eutrophus* strains were isolated. One of those strains, strain B9, differed from *C. necator* N1 and *C.eutrophus* H16 on several aspects. For instance, strain B9 was not able of autotrophic growth but was copper resistant (up to 1.2 mM). The strain features a plasmid that differs in size in comparison to the one observed in *R. eutropha* H16. Strain B9 was therefore characterized through genomic sequencing and a total of 516 contigs were obtained (Illumina sequencing, N50=25246 pb).

**Conclusions**

Preliminary analyses of the contigs confirm the absence of *cbb* genes necessary for autotrophy and show the presence of a ~70kb region containing metal detoxication genes (mainly copper but also a mercury resistance *merRTPCA* operon) also found in environmental *Ralstonia pickettii* strains and mainly an extended cluster of *cop* genes (*cop KH3SRABCDIH2JGFOL1L2QH*) largely syntenic with the *cop* region of *C. metallidurans* plasmid pMOL30.

**Metals and microbes**

## **METAGENOMIC PROFILING OF MICROBIAL METAL INTERACTION IN RED SEA DEEP-ANOXIC BRINE POOLS' WATER**

M.M. Hanna<sup>1</sup>, R. Siam<sup>2</sup>

<sup>1</sup>*Biotechnology Graduate Program, The American University in Cairo, New Cairo, Egypt*

<sup>2</sup>*Department of Biology, The American University in Cairo, New Cairo, Egypt*

### **Background**

Different geochemical studies reported high metal abundance in Red Sea deep-anoxic brine pools, especially in Atlantis II Deep, which has the highest metals content. Brine pools showed wide diversity of biologically essential and non-essential metals. Several metals known for their toxicity to biological life were detected in these pools. Yet, our previous microbiome analyses of the pools demonstrated vast microbiological diversity.

### **Objectives**

In this study, we compare metal-resistant prokaryotic microbiomes in different metal-rich brine water samples from; Atlantis II lower convective layer (ATII-LCL), Atlantis II upper convective layer (ATII-UCL), Discovery Deep (DD) and Kebrit Deep (KD). Moreover, we investigate genome evolution of microbial communities in response to such excessive metal abundance.

### **Methods**

Using 16S rRNA pyrotags and shot-gun 454-pyrosequencing, we perform a comparative analyses of a-taxonomic assignment of Operational Taxonomic Units to major bacterial and archaeal groups and b-metal resistant protein-coding genes, of the microbial communities and metagenomes. The ATII-LCL, ATII-UCL, DD and KD brine pools metagenomes protein-coding genes involved in microbial-metal interaction and resistances were assessed for abundance, diversity and novelty.

### **Conclusions**

We report specific microbial diversity of these three brine pools. Functional analyses of the metagenomes revealed different metal resistance mechanisms. This was supported by the strong correlation between specific high metal/s concentration in selected brine water, where; metal resistance, enrichment of metals metabolism and transport were revealed. As expected, ATII-LCL showed the highest relative abundance of genes involved in microbial-metal interaction. Additionally, we report significant abundance of peroxidases-encoding genes, mainly in ATII-LCL, and we hypothesize that generation of H<sub>2</sub>O<sub>2</sub> occurs through interaction of pyrite deposits.

#### **CATION METABOLISM AND TRANSLOCATION IN BROWN ROT WOOD DEGRADING FUNGI**

J. Jellison<sup>1</sup>, B. Goodell<sup>2</sup>, G. Kirker<sup>3</sup>, S. Zelinka<sup>3</sup>, W. Shortle<sup>4</sup>, J. Schilling<sup>5</sup>, J. Jakes<sup>3</sup>

<sup>1</sup>Plant Pathology Physiology and Weed Science, Virginia Tech, Blacksburg, USA

<sup>2</sup>Dept. of Sustainable Biomaterials, Virginia Tech, Blacksburg Va, USA

<sup>3</sup>Forest Products Lab, USDA-FS, Madison WI, USA

<sup>4</sup>Northern Research Station, USDA-FS, Durham NH, USA

<sup>5</sup>Dept. of Bioproducts and Biosystems Engineering, University of Minnesota, St. Paul Mn, USA

#### **Background**

The brown rot fungi are important components of the coniferous northern hemisphere forest ecosystem and are characterized by their ability to colonize and degrade lignocellulosic materials; preferentially metabolizing hemicellulose and cellulose components and leaving a residue of modified lignin. Multiple aspects of the metabolism and degradative capabilities of these organisms are dependent upon cations, including but not limited to iron, manganese, and calcium.

#### **Objectives**

As wood degrades, it is characterized by decreasing pH and increasing concentrations of selected cations. The decay fungi, as they colonize wood, differentially translocate cations and actively modulate their ionic environment. The base cations are needed for many metabolic functions including membrane stabilization and they also function as enzyme cofactors and electrolytes. Transition metals are directly involved in lignocellulose degradation. We will examine the influence of cation concentrations on fungal sheath formation, and the activity of a biologically unique iron-based non-enzymatic degradative system in the brown rots.

#### **Methods**

The role of iron in the chelator-mediated Fenton (CMF) system will be examined as it is particularly crucial to the ability of the brown rot fungi to depolymerize lignocellulose. Methods used include but are not limited to ICP and XFM. Organisms used in this work include: *Serpula lacrymans*, *Postia placenta*, *Fomitopsis pinicola* and *Gloeophyllum trabeum*.

#### **Conclusions**

The role played by transition metals, pH, oxalate production and calcium oxalate crystal formation in brown rot physiology and cell wall breakdown mechanisms is discussed along with the potential ecological significance of cation mobilization and redistribution within the forest floor ecosystem.

**ADHESIN COMPETENCE REPRESSOR (ADCR) FROM STREPTOCOCCUS PYOGENES CONTROLS ADAPTIVE RESPONSES TO ZINC LIMITATION AND CONTRIBUTES TO VIRULENCE**

M. Kumaraswami<sup>1</sup>, M. Sanson<sup>1</sup>, N. Makthal<sup>1</sup>, J. Musser<sup>1</sup>, R. Olsen<sup>1</sup>

<sup>1</sup>Pathology and Genomic Medicine, Houston Methodist Research Institute, Houston, USA

**Background**

Altering zinc bioavailability to bacterial pathogens is a key component of host innate immunity. Thus, the ability to sense and adapt to the alterations in zinc concentrations is critical for bacterial survival and pathogenesis.

**Objectives**

To understand the adaptive responses of group A *Streptococcus* (GAS) to zinc limitation

To elucidate the regulation of adaptive responses by metalloregulator AdcR

**Methods**

RNA sequencing

Gel mobility shift assay

qRT-PCR

animal infection studies

X-ray crystallography

**Conclusions**

AdcR regulates the expression of 70 genes involved in zinc acquisition and virulence. Zinc-bound AdcR interacts with operator sequences in the negatively regulated promoters and mediates differential regulation of target genes in response to zinc deficiency.

Genes involved in zinc mobilization and conservation are derepressed during mild zinc deficiency, whereas the energy-dependent zinc importers are upregulated during severe zinc deficiency.

We also demonstrated that transcription activation by AdcR occurs by direct binding to the promoter. However, the repression and activation by AdcR is mediated by its interactions with two distinct operator sequences.

Mutational analysis of the metal ligands of AdcR caused impaired DNA binding and attenuated virulence, indicating that zinc sensing by AdcR is critical for GAS pathogenesis. Together, we demonstrate that AdcR regulates GAS adaptive responses to zinc limitation and identify molecular components required for GAS survival during zinc deficiency.

**MECHANISMS OF CHROMATE RESISTANCE AND REDUCTION BY  
KLEBSIELLA PNEUMONIAE CHROAq1 ISOLATED FROM A CHROMIUM  
CONTAMINATED AQUIFER**

P. Lara<sup>1</sup>, E. Morett<sup>1</sup>, K. Juárez<sup>1</sup>

<sup>1</sup>Cell Engineering and Biocatalysis, Biotechnology Institute UNAM,  
Cuernavaca Morelos, Mexico

**Background**

Chromium-reducing microorganisms as well as their enzymes chromate-reductases have taken great interest due to their potential application in bioremediation processes. They are phylogenetic and metabolically diverse; in some cases Cr(VI) reduction is result of the metal respiration as in *Geobacter*. However in other microorganisms like genus *Klebsiella* has little knowledge about the metal reduction mechanisms.

**Objectives**

The present study was aimed at the characterization the mechanisms of Cr(VI) resistance and reduction in *Klebsiella pneumoniae* ChroAq1, isolated from long-term Cr(VI)-contaminated aquifer located in Guanajuato, México.

**Methods**

It was determined the ability to reduce Cr(VI) to Cr(III) by growing cells and cell-free extracts of *K. pneumoniae* ChroAq1. The cellular fractionation was performed by ultracentrifugation. Moreover the complete genome of ChroAq1 was sequenced with illumina technology, automatically annotated and analyzed. Some putative genes involved in resistance and reduction were deleted by **double recombination**.

**Conclusions**

The isolated strain ChroAq1 was identified as *Klebsiella pneumoniae*, its resistance observed was 1.8mM of Cr(VI) in anaerobic conditions and 22mM in aerobic conditions and was able to reduce Cr(VI) only anaerobically. The cell-free extract from this strain showed a NAD(P)H-dependent chromate-reductase activity associated to the soluble cell fraction. The gen *chrA* is present in the genome of

ChroAq1 however its deletion did not abolish the chromate resistance. In other hand, we deleted four genes presumptively involved in Cr(VI) reduction, one encodes a protein 84.57% identical to YieF (ABJ74146), other encodes one 86.58% identical to NemA (P77258) from *E. coli*, however they had no effect on the chromate reduction capability, the other two are being studied.

**PRODUCTION OF SELENIUM AND ZINC ENRICHED BIOMASS AND NANOPARTICLES USING LACTOBACILLI**

V. Lule<sup>1</sup>, K. Saini<sup>1</sup>, S. Sequeira<sup>1</sup>, S.K. Tomar<sup>1</sup>

<sup>1</sup>Dairy Microbiology, NATIONAL DAIRY RESEARCH INSTITUTE, KARNAL, India

**Background**

Selenium (Se) and Zinc (Zn), are the trace elements which play a pivotal role in humans well-being. Symptoms resulting from deficiency of these essential metals are diverse but chronic and severe and if untreated, can prove fatal. Bioproduction of Se and Zn enriched biomass and nanoparticles by lactobacilli can be explored and exploited for development of dietary organic sources of these minerals to overcome the mineral deficiencies and to improve the human health.

**Objectives**

To produce Se and Zn enriched biomass and Se<sup>0</sup> and zinc oxide nanoparticles using lactobacillus spp.

**Methods**

Fifty human origin lactobacilli were screened for their ability to accumulate Se and Zn by growing them on medium added with different concentration of sodium selenite and zinc sulfate respectively. Estimation of Se and Zn accumulated by cultures was carried out by ICPES and AAS, respectively. Selected cultures were used for biogenic production of Se and ZnO nanoparticles and their size were determined by Scanning Electron Microscope.

**Conclusions**

Among all the isolates, *L. reuteri* NCDC77 was found to have greater ability to accumulate Se (820 µg/g dry weight) coupled with potential probiotic properties while *L. plantarum* YM2C was able to accumulate large amount of Zn (1.32mg/g dry weight). In addition, nanoparticles of Se and Zn produced by the selected strains, were found to be in the range of 100-200nm. Harnessing these potential cultures can serve as a novel application of these cell factories for the production of Se and Zn enriched functional foods and as dietary supplement.

**ACCURATE MINIMAL INHIBITORY CONCENTRATION PREDICTION FOR CUPRIAVIDUS METALLIDURANS CH34 USING A TOXICITY MODEL BASED ON TWO CHEMICAL METAL-ION CHARACTERISTICS**

H. Moors<sup>1</sup>, P. Monsieurs<sup>1</sup>, R. Van Houdt<sup>1</sup>, M. Mergeay<sup>1</sup>, N. Leys<sup>1</sup>

<sup>1</sup>Microbiology, SCK•CEN, Mol, Belgium

**Background**

The inhibitory effect of metal(-ion)s on the growth of microorganisms is mainly determined by their chemical binding properties to essential biochemical molecules (e.g. thiols, proteins, enzymes, RNAs, DNA) and the effective intracellular concentration. Active control of the intracellular metal-ion concentration is one of the successful survival strategies microorganisms use against toxic metal-ion concentrations and they can harbor a variety of resistance systems to control the intracellular concentration of different metal-ions. *Cupriavidus metallidurans* CH34 is one of the model bacteria used to study survival in the presence of elevated metal-ion concentrations. Numerous studies have been performed using *C. metallidurans* CH34 to elucidate its various metal-ion defense mechanisms. As a consequence, a substantial amount of physical, chemical and biological data is available on the impact of several metal-ions on the behavior of *C. metallidurans* CH34.

**Objectives**

To test whether it is possible to establish a metal-ion toxicity model that is able to predict the Minimal Inhibitory Concentration for *C. metallidurans* CH34.

**Methods**

A two-variable metal-ion characteristics toxicity model, based on  $|\log K_{OH}|$  ( $K_{OH}$  = first hydrolysis constant) and  $\chi^2_{m.r}$  (= covalent index), that efficiently correlates ( $r^2=0.90$ ) with the measured MIC of 20 different metal ions, has been developed for *C. metallidurans* CH34 cultivated in chelating-free mineral medium. To test this chemical model for its applicability, the MIC of  $Pd^{2+}$  was first calculated and afterwards experimentally determined.

**Conclusions**

The model prediction, 0.032 mM, corresponded very well to the measured MIC of 0.029 mM, indicating that the two metal-ion characteristics,  $K_{OH}$  and  $\chi^2_{m.r}$ , can be used to reliably predict MIC values.

Portugal

<sup>3</sup>Faculdade de Farmácia/Faculdade de Ciências da Nutrição e Alimentação.,  
UCIBIO/REQUIMTE. Universidade do Porto, Porto, Portugal

<sup>4</sup>Microbiologia, Ramón y Cajal Hospital, Madrid, Spain

**Background**

Successful bacteria accumulated different genetic features shaping their evolution and fitness to diverse environments/hosts. Mercury (Hg) is widespread in Nature and possibly contributed for selection of particular strains.

**Objectives**

To evaluate the dispersion of diverse *merA* alleles among enterococci from several origins and clonal backgrounds.

**Methods**

*merA* alleles was searched in *Enterococcus* available genomes, used to construct a maximum-likelihood phylogenetic tree. A PCR scheme+RFLP+sequencing was developed to detect the six *merA* alleles identified, namely I-(GenBank-AECE01000068), IIA-(AIUL01000023.1), IIB-(ASDU01000008.1), III-(NZ\_KB947199.1), IV-(AECE01000068.1) and VI-(NZ\_KB030055.1), among 918 *Enterococcus* (Portugal; human/animal/environment/food; 1996-2012). Clonality was evaluated by PFGE/MLST, *merA*-transfer by conjugation and Hg-phenotype in m\_Enterococcus+128mg/L HgCl<sub>2</sub>.

**Conclusions**

*merA* were found in 4% (n=37/918) of *Enterococcus* studied. PCR+RFLP+sequencing distinguished the six alleles previously found at Genbank and a new one (type V). They were distributed among diverse sources and clones, in our and GenBank isolates: types I and IV-human *E. faecalis* (*Efls*; n=5; USA; 1987-88; ST9/ST206); IIA-human/pig/trout/feed/hospital-sewage *E. faecium*-

*Efm/E.hirae/Enterococcus\_sp* (n=17/1/1; Portugal/France/Denmark/Germany; 1989-2012; 12ST-*Efm* including from ST78-ST17-ST18-lineages-CC17); IIB-human *Efls/E.dispar* (n=2/1; Portugal/USA; 1926-2001; ST206/ST105/ST107); III-human/animal/hospital-sewage *Efls/E.casseliflavus* (n=15/1; Portugal/France/USA/Canada/Japan; 1961-2012; ST64/ST9/ST30/ST159/ST245); V-human/trout/pig-manure *Efm* (n=4; Portugal; 2001-2006; ST94/ST890); VI-human/hospital-sewage/piggery-soil/piggery-manure/trout *Efm* (n=23; Portugal, Italy France, Germany, Denmark, Hungary, Switzerland, Ireland, Norway, Brazil, USA; 1961-2012; 14ST including ST78-ST17-ST18-lineages-CC17). The presence of *merA* among major *Efm/ST9-Efls* lineages associated with human infections, suggests that mercurial-compounds potentially contributed for their selection/maintenance. *merA*<sup>+</sup>-*Enterococcus* grown in >128mg/L-HgCl<sub>2</sub>. Transfer occurred for IIA and VI alleles. All but VI-*merA* alleles, were also identified in genomes of different species of Firmicutes (data not shown), suggesting genetic exchange of enterococci with bacteria sharing the same communities/environmental challenges.

**THE SENSORY PROTEIN HBPS FROM THE SOIL BACTERIUM STREPTOMYCES RETICULI SPECIFICALLY INTERACTS WITH IRON, HEME AND AQUO-COBALAMIN**

D. Ortiz de Orue Lucana<sup>1</sup>, I. Wedderhoff<sup>1</sup>, A. Torda<sup>2</sup>, S. Fedosov<sup>3</sup>

<sup>1</sup>Biology/Chemistry, University of Osnabrück, Osnabrück, Germany

<sup>2</sup>Centre for Bioinformatics, Hamburg University, Hamburg, Germany

<sup>3</sup>Department of Engineering Science, Aarhus University, Aarhus, Denmark

**Background**

A novel type of redox-signaling system has been recently characterised in bacteria, the HbpS-SenS-SenR system from streptomycetes. The extracellular HbpS protein binds ferrous ions, heme and aquo-cobalamin.

**Objectives**

Elucidation of molecular mechanisms that modulate the function of HbpS-SenS-SenR, and analyses of binding sites as well as binding kinetics in HbpS-ligand interactions.

**Methods**

Disruption and site-directed mutagenesis; growth assays; crystallization; FRET, UV/Vis and CD spectroscopy; bioinformatics

**Conclusions**

HbpS-SenS-SenR is involved in the protection of *Streptomyces* against oxidative stress and is conserved in many other actinobacteria. HbpS acts as an accessory module of the two-component system SenS-SenR. Analysis of the HbpS crystal structure and biochemical studies revealed that HbpS assembles as an octamer that is crucial for interaction with the sensor kinase SenS. Under conditions of oxidative stress this leads to the autophosphorylation of SenS that, in turn, phosphorylates the response regulator SenR. This activates the transcription of anti-oxidative genes.

HbpS sequesters large quantities of ferrous iron ions which might protect *Streptomyces* from the effects of iron-based oxidative stress. HbpS is also an unusual heme-binding protein in which a specific threonine apparently binds to the tetrapyrrole macrocycle. *In vitro* and *in vivo* studies have also shown that HbpS can degrade heme. This activity may be responsible for HbpS-mediated protection against toxic concentrations of heme. Moreover, HbpS binds aquo-cobalamin. The calculated  $K_d$  of 34  $\mu$ M suggests that HbpS might bind aquo-cobalamin in both bacterial cultures and in the *Streptomyces* natural environment the soil. The physiological relevance of this interaction remains, however, to be elucidated.

## **CALCIUM CARBONATE MINERALIZATION IN BACILLUS SUBTILIS: STUDIES AND APPLICATIONS**

B. Perito<sup>1</sup>, F. Di Benedetto<sup>2</sup>, M. Marvasi<sup>1</sup>, G. Mastromei<sup>1</sup>, M. Passaponti<sup>1</sup>, P. Tiano<sup>3</sup>

<sup>1</sup>Department of Biology, University of Florence, Sesto Fiorentino (Florence), Italy

<sup>2</sup>Department of Earth Sciences, University of Florence, Florence, Italy

<sup>3</sup>Institute for the Conservation and Promotion of Cultural Heritage, ICVBC-CNR, Sesto Fiorentino (Florence), Italy

### **Background**

Calcium carbonate precipitation is a widespread phenomenon among bacteria, with relevant implications in natural processes and great potentiality in numerous applications. Nevertheless, the molecular aspects of the process are still unknown.

### **Objectives**

We have been studying CaCO<sub>3</sub> precipitation in the model bacterium *Bacillus subtilis* by different multidisciplinary approaches to identify: a) bacterial genes, and b) cell structure(s), involved in biomineralization; c) analytical markers able to distinguish the "biosignature" of natural calcite.

### **Methods**

For objective a), we produced *B. subtilis* mutants by insertional mutagenesis and checked their precipitation phenotype. For objective b), we tested bacterial dead cells and cell fractions in a suitable precipitation test in solution. For objective c), we analyzed calcite crystals produced by *B. subtilis* by X-ray powder diffraction (XRPD) and Electron Paramagnetic Resonance (EPR) spectroscopy.

### **Conclusions**

By analysis of mutants impaired in calcite formation, we identified a gene cluster as involved in the process, and two genes of the cluster, *etfA* and *etfB*, as the minimal gene set necessary for precipitation.

The *B. subtilis* cell wall fraction, called BCF, was able to induce calcite formation in solution. BCF was applied on stone specimens and on a monumental site as an eco-friendly biotreatment for stone consolidation. New calcite formation and a little cohesion increase were observed in the treated stones.

Both XRPD and EPR revealed unusual spectral parameters, attributed to the effects of the bioprecipitation of the mineral. The resultant spectroscopic fingerprint of bacterial calcite would be useful for identifying traces of bacterial activity in fossil carbonate deposits.

**FEMS-1149**

**Metals and microbes**

### **ALUMINUM TOXICITY AND TOLERANCE IN MICROORGANISMS**

*T. Aizawa-Urai<sup>1</sup>, X.Q. Zhao<sup>1</sup>, J. Sato<sup>1</sup>, N. Ohara<sup>1</sup>, A. Shiina<sup>1</sup>, M. Sunairi<sup>1</sup>*

*<sup>1</sup>Applied Biological Sciences, Nihon University, Fujisawa Kanagawa, Japan*

#### **Background**

In acid soils below pH 4.5, aluminum becomes more soluble and toxic to plants, a few micronutrients, such as manganese and iron, become more soluble and toxic; and most plant nutrients, such as phosphorus, become more limited. This situation can cause serious destruction of the environment and significant economic problems. To overcome these problems, understanding of the toxicity of acid soils and the tolerance mechanisms in plants and microorganisms, especially the Al-toxicity and tolerance mechanisms, is essential.

#### **Objectives**

We have isolated many plants and microorganisms well adapted to highly acidic soils. Although there have been numerous reports on molecular mechanisms of Al tolerance in plants and microorganisms, such as organic acid secretion, alteration of cell walls, and Al-sequestration, our isolates suggested the complexity of the mechanisms of Al toxicity and tolerance. In this study we studied the Al-toxicity and tolerant mechanisms.

#### **Methods**

Microorganisms: *Acidocella aluminidurans* NBRC 104303(T), *Burkholderia bannensis* NBRC 103871(T), *B. acidipaludis* NBRC 101816(T) and 103872, *B. helei* NBRC 101817(T), *Pullulanibacillus* sp. CA42, *Rhodotorula taiwanensis* CGMCC 2.4753, and *Saccharomyces cerevisiae* BY4741 and their derivatives.

Al tolerance test: Low phosphate synthetic minimal medium containing 1% glucose was buffered with 5 M succinic acid at pH 4.5. Cells were cultured in the presence of different concentrations Al at 28°C.

#### **Conclusions**

The results suggest that in addition to the aforementioned mechanisms of Al tolerance, an extracellular polysaccharide, cellular functions, and alteration of

membrane lipids, are relevant with the Al toxicity and tolerance. The knowledge will greatly help to overcome the acid soil problems.

**REDUCTION OF CHALCOGEN OXYANIONS AND BIOGENESIS OF NANOPARTICLES BY *OCHROBACTRUM* SP. MPV1**

E. Zonaro<sup>1</sup>, S. Lampis<sup>1</sup>, G. Vallini<sup>1</sup>

<sup>1</sup>Department of Biotechnology, University of Verona, Verona, Italy

**Background**

Metal nanoparticles have been produced using chemical and physical methods for many years. However, the exploitation of strong reducing agents may lead to undesired toxicity issues. It is, therefore, important to develop alternative and ecofriendly methods. Recently biosynthetic methods employing microorganisms have emerged as simple and viable alternative to produce metal/metalloid nanoparticles. In particular, the chalcogens selenium and tellurium in their elemental forms exhibited interesting antimicrobial activity. Moreover, nanoparticles produced with these elements show intriguing optoelectronic and semiconducting properties.

**Objectives**

A microbial strain characterized as *Ochrobactrum* sp. MPV1, isolated from the highly metal-polluted site of Scarlino (GR), was studied for its ability of effectively reducing both the oxyanions selenite and tellurite to their elemental forms in aerobic conditions and consequently producing elemental selenium and tellurium nanoparticles.

**Methods**

The isolate is capable of reducing 2 mM  $\text{SeO}_3^{2-}$  in 48 hours and 0.3 mM  $\text{TeO}_3^{2-}$  in 96 hours. The intracellular accumulation of nanoprecipitates was demonstrated through SEM-EDX and TEM analysis. Moreover, several analysis were performed in order to shed light on the mechanisms involved in selenite and tellurite reduction to the elemental state. The results obtained suggest that selenite and tellurite are reduced through two different mechanisms in *Ochrobactrum* sp. MPV1. Glutathione seems to play a major role in selenite reduction, while tellurite reduction could be ascribed to the catalytic activity of intracellular NADH-dependent oxidoreductases.

**Conclusions**

In conclusion, *Ochrobactrum* sp. MPV1 is an ideal candidate for the biogenesis of  $\text{Se}_0$  and  $\text{Te}_0$  nanoparticles, with possible biotechnological and industrial applications.

**INVESTIGATION OF FACTORS DETERMINING STRESS RESISTANCE OF SOLVENTOGENIC BACTERIAE STRAIN CLOSTRIDIUM ACETOBUTYLICUM DERIVED BY ADAPTIVE SELECTION METHOD**

A. Balotnik<sup>1</sup>, N.E. Litvinovich<sup>1</sup>, T.E. Kirpicheva<sup>1</sup>, E.I. Kolomiets<sup>1</sup>, M.A. Titok<sup>1</sup>

<sup>1</sup>Belarus National Academy of Sciences, Institute of Microbiology, Minsk, Belarus

**Background**

Biobutanol is a promising type of motor fuel and feedstock for chemical industry.

**Objectives**

To elaborate efficient technology of biobutanol manufacturing from renewable materials adaptive selection technique was applied to derive solventogenic bacterial strain *Clostridium acetobutylicum* producing butanol in concentration up to 18.7 g/l. It was shown that the selected bacterial strain when compared to the parent strain was capable to withstand 1.3 times higher butanol level and was distinguished by osmotolerance, resistance to temperature impact and antibiotic chloramphenicol.

**Methods**

To define the factors governing enhanced resistance of selected strain *C. acetobutylicum* to stress exposure, lipid fatty acid composition of cellular membranes in the parent and butanol-adapted clostridial strains was analyzed. Using real-time PCR technique, we carried out comparative examination of expression of heat shock gene *groEL* and key gene *adhE* responsible for butanol biosynthesis in parent and adapted clostridial strains grown on butanol and solvent-free media.

**Conclusions**

It was found that the ratio of saturated to unsaturated acids is 1.84 times higher in butanol adapted strain *C. acetobutylicum* than in parent strain, which leads to stabilization of structure, promotes membrane fluidity and induces resistance to stress factors.

It was established that expression of *groEL* gene in the parent strain declined 100-fold on butanol-containing media, while expression of gene *adhE* was not recorded, in contrast to adapted strain *C. acetobutylicum* showing only minor decrease of gene expression under similar conditions. The obtained results indicate that cell metabolism of adapted bacterial strain was less sensitive to adverse butanol effects as compared to wild-type bacteria.

Poland

#### **Background**

The start-up of trial operation of biogas plant usually consists of adding leachate from other biogas plants or inoculation by cattle slurry. An alternative to the traditional start-up operation is the use of the freeze-dried microbial consortia that were previously selected in anaerobic digestion process.

#### **Objectives**

The aims of this work were investigate the effects of freeze-drying of methanogenic consortium selected from agriculture anaerobic digestion plant on: (i) biogas production efficiency and (ii) stability of microbial community structure.

#### **Methods**

Lab-scale anaerobic digestion process. Freeze-drying. Biogas yield: daily biogas production, methane content were analyzed by gas chromatography GC-MS. Physical and chemical analysis: pH, volatile fatty acids (VFA), chemical oxygen demand (COD), ammonium. Determination of total cell counts by fluorescence microscope (Japan) using the filter set WU for DAPI detection. DNA and RNA isolation. PCR amplification and 16S rRNA gene amplicons libraries.

#### **Conclusions**

The conducted analyses revealed that the consortium selected from anaerobic digester plant is active and able to effectively produce biogas after long-term storage. 16S rRNA gene amplicon libraries analyses showed that the microbial consortia have the same methanogenic community composition after long-term storage. These results demonstrated that described method for long-term storage and revitalization of methanogenic consortia could be used as a starter to quick start-up industrial process of biogas production.

## **GENETIC ENGINEERING OF CYANOBACTERIA FOR HYDROGEN PRODUCTION**

G. Kufryk<sup>1</sup>

<sup>1</sup>*College of Science Engineering and Technology, Grand Canyon University, Phoenix, USA*

### **Background**

Hydrogen can be naturally produced by several groups of organisms, including cyanobacteria. As a biofuel, hydrogen has substantial advantages over carbon-based compounds as it does not generate carbon dioxide and other atmospheric pollutants, and has a higher mass energy density than any other fuel. However, the current cost of its industrial production and the low yield of hydrogen by living organisms are not conducive to increasing its use as an environmentally friendly alternative to the traditional fuels.

### **Objectives**

Our goal was genetic engineering of cyanobacteria for the purpose of increasing the yield of hydrogen that was generated by these strains.

### **Methods**

For this purpose, we employed homologous and heterologous expression of hydrogenases in cyanobacteria.

### **Conclusions**

Genetic engineering of cyanobacteria allowed us to significantly increase their hydrogen-producing capacity without compromising the stability of the mutant strains. As the details of molecular regulation of hydrogen production in the cell become increasingly available, new steps are being taken to improve the level of hydrogen production by cyanobacteria. Due to a photoautotrophic nature and low maintenance cost of these microorganisms, they represent the most economical system for biological hydrogen production with a potential for commercial application.

**NEW GENETIC APPROACH TO ENGINEERING OF MUTANT STRAINS OF  
CYANOBACTERIUM ANABAENA VARIABILIS ATCC 29413 WITH ENHANCED  
LEVELS OF BIOHYDROGEN PHOTOPRODUCTION**

L. Mikheeva<sup>1</sup>, O. Zhenavchuk<sup>1</sup>, E. Karbysheva<sup>1</sup>, S. Shestakov<sup>1</sup>

<sup>1</sup>Biological faculty, Lomonosov Moscow State University, Moscow, Russia

**Background**

Heterocystous cyanobacteria are capable to efficient nitrogenase-dependent H<sub>2</sub>-photoproduction in the case of mutational elimination of uptake hydrogenase activity. In this study we used previously isolated chemically induced H<sub>2</sub>-producing mutants of *A. variabilis* PK84 and PK17 with impaired activity of uptake hydrogenase and also ammonium producing ethylenediamine-resistant (ER<sup>R</sup>) mutants ED21 and ED93 characterized by derepressed levels of nitrogenase activity and low levels of glutamine synthetase activity. Our sequencing data revealed the point mutations in conservative sites of genes *hypF* (PK84: Asp374Asn), *hupL* (PK17: Cys446Tyr), *glnA* (ED21: Ala382Thr, ED93: Pro465Leu).

**Objectives**

The construction of *A. variabilis* strains with mutations in both *hypF* (or *hupL*) and *glnA* genes and analysis of their H<sub>2</sub>-producing capacities in comparison with reference strains PK84 and PK17.

**Methods**

The mobilizable plasmid vector pRL498 was used for cloning and transfer of DNA fragments with mutations into *Anabaena* cells via triparental mating with *E. coli*. Mutant strains PK84 and PK17 were used as recipients for cloned fragments with *glnA*-mutations (with selection of ED<sup>R</sup> recombinants) whereas mutants ED21 and ED93 were recipients for *hypF* or *hupL* genes inactivated by insertion of spectinomycin resistance cassette (with selection of Sp<sup>R</sup> recombinants)

**Conclusions**

In both variants of gene transfer we have selected some biotechnologically perspective double mutants with lower growth rate and higher level of H<sub>2</sub>-production compared with strains PK84 and PK17 (up to 130 % per biomass unit) that might be explained by enhanced levels of nitrogenase activity accompanying by a partial block in biosynthetic or assimilatory processes caused by additional alterations in *glnA* gene.

## **IMMOBILIZED BIOCATALYSTS FOR BIODIESEL FUEL PRODUCTION**

N. Almyasheva<sup>1</sup>, D. Kopitsyn<sup>1</sup>, D. Beskorovaynaya<sup>1</sup>, A. Novikov<sup>1</sup>

<sup>1</sup>*Physical and Colloid Chemistry, Gubkin Russian State University of Oil and Gas, Moscow, Russia*

### **Background**

Biodiesel comprising of fatty acid alkyl esters is a promising alternative fuel. The biodiesel fuel can be produced under milder conditions and with fewer steps using biocatalysts instead of conventional alkali catalyst. In order to increase the biocatalyst stability and to ensure its easy separation from the biodiesel fuel, it is required to immobilize the biocatalyst on a suitable carrier. The comparison of biodiesel fuel production with different immobilized biocatalysts will be helpful for the process optimization and for further industrial implementation.

### **Objectives**

In our work, we studied the immobilization of lipases on silica, diatomite, and ion exchange resins, and the immobilization of yeast cells and mycelium on both soft (polyurethane foam) and rigid (haydite) carriers to perform the comparison of different immobilized biocatalysts in stirred-tank and packed bed bioreactors.

### **Methods**

*Pseudomonas fluorescens* lipase, *Rhizopus oryzae* lipase, Lipase B *Candida antarctica*, glutaraldehyde, tributyrine, and triglycerides standards were from Sigma-Aldrich. *Aspergillus niger* DSM823 and *Yarrowia lipolytica* DSM8218 strains were from DSMZ. Activity of biocatalysts was assayed by the hydrolysis of tributyrine with analysis of butyric acid by GC. Methanolysis of triglycerides was controlled by HPLC. The immobilization of microorganisms was controlled by SEM (see Fig.1, DSM8218 on haydite, bar 10 µm).

### **Conclusions**

The highest yield of biodiesel fuel (fatty acid methyl esters) was observed for the DSM823 mycelium immobilized on polyurethane foam in packed bed bioreactor. This suggests the whole-cell biocatalysis in continuous mode bioreactors is the most promising approach in biodiesel fuel production.

## **THE USE OF MIXED HYDROLYTIC BACTERIA IN THE PRODUCTION OF SUPPLEMENTS ENHANCING BIOGAS PRODUCTION PROCESS**

K. Poszytek<sup>1</sup>, M. Cieczkowska<sup>1</sup>, A. Skłodowska<sup>1</sup>, L. Drewniak<sup>1</sup>

<sup>1</sup>Laboratory of Environmental Pollution Analysis,  
University of Warsaw Faculty of Biology, Warsaw, Poland

### **Background**

During the degradation of the lignocellulosic biomass by hydrolytic bacteria many organic compounds such as: volatile fatty acids, simple carbohydrates and many intermediate metabolites are released. These compounds are used by successive groups of microorganisms involved in the subsequent stages of anaerobic digestion process.

### **Objectives**

The main aim of this study was (i) degradation of lignocellulosic biomass (maize silage) by mixed hydrolytic bacteria and (ii) production of supplements dedicated for enhanced biogas production.

### **Methods**

(I) Preparation of the supplements: aerobic degradation of lignocellulosic biomass (3% d.m. of corn silage) by mixed hydrolytic bacteria for 72 hours at 30°C at pH 7. Centrifugation and extraction of the supernatant from the culture. (II) Analysis of influence of produced supplements on anaerobic digestion. Lab-scale anaerobic digestion process. Biogas yield: daily biogas production, methane content were analyzed by gas chromatography GC-MS. Physical and chemical analysis: pH, volatile fatty acids (VFA), chemical oxygen demand (COD), total solids (TS), volatile solids (VS).

### **Conclusions**

In the presented work it was showed that the mixed hydrolytic bacteria can be used for preparation of supplements dedicated for the methane fermentation process. The results demonstrate that supplements produced by hydrolysis mediated by mixed hydrolytic bacteria, can increase the efficiency of biogas production up to 20-30%. Such supplements can be used in both well-working biogas plants in order to increase the efficiency of the biogas production process.

**ANAEROBIC CO-DIGESTION OF HARDLY BIODEGRADABLE ORGANIC MATERIALS WITH THE USE OF MAIZE SILAGE**

K. Poszytek<sup>1</sup>, M. Cieczkowska<sup>1</sup>, J. Chilimoniuk<sup>1</sup>, A. Skłodowska<sup>1</sup>, L. Drewniak<sup>1</sup>

<sup>1</sup>Laboratory of Environmental Pollution Analysis,  
University of Warsaw Faculty of Biology, Warsaw, Poland

**Background**

Many organic residues are often used as a substrate in anaerobic digestion, but the efficiency of the process is determined by the level of biodegradability of waste materials. To increase digester gas production from hard-degradable compounds various co-digestion process are applied. If co-substrates are used in anaerobic digestion system it improves the biogas yields due to positives synergisms established in the digestion medium and the supply of missing nutrients.

**Objectives**

The main aim of this study was to verify if maize silage, which is the most popular substrate used in production of biogas in agriculture plants, can be also a valuable co-substrate used for utilization of hardly biodegradable substrates such as sewage sludge waste (SSW) or residues from coal mines (RCM).

**Methods**

Laboratory anaerobic digestion process in various ratio corn silage and utilization of waste (3%, 2+1%, 1+2%, 0%). Biogas yield: daily biogas production, methane content were analyzed by gas chromatography GC-MS. Physical and chemical analysis: pH, volatile fatty acids (VFA), chemical oxygen demand (COD), total solids (TS), volatile solids (VS). Determination of total cell counts by fluorescence microscope, using the filter set WU for DAPI detection.

**Conclusions**

Obtained results showed that maize silage can be used as valuable co-substrates during utilization of various industrial waste materials. The addition of only 1% of the dry matter of maize silage to sewage sludge waste and residues from coal mine increased the biogas yield (even up to 300%).

## **CHARACTERIZATION OF AN ANAEROBIC THERMOPHILIC GLYCEROL-DEGRADING ENRICHMENT CULTURE**

J.A. Ribeiro<sup>1</sup>, A.J. Cavaleiro<sup>1</sup>, D.Z. Sousa<sup>2</sup>, M.M. Alves<sup>1</sup>, A.J.M. Stams<sup>2</sup>

<sup>1</sup>Centre of Biological Engineering, University of Minho, Braga, Portugal

<sup>2</sup>Laboratory of Microbiology, Wageningen University, Wageningen, Netherlands

### **Background**

The glycerol market was totally changed by the biodiesel industry, which resulted in the production of an excess of this compound as an industrial by-product. As a consequence, the price of glycerol dropped and a huge interest in alternatives for its valorisation emerged since then. In the field of Biotechnology research, glycerol is an attractive compound for the microbial production of chemical building blocks.

### **Objectives**

The aim of this work was to investigate thermophilic anaerobic communities capable of conversion of glycerol.

### **Methods**

Thermophilic sludge from a lab-scale anaerobic reactor fed with skim milk and sodium oleate (50:50% chemical oxygen demand) was incubated at 55°C in closed bottles containing bicarbonate-buffered medium supplemented with 10mM glycerol. Periodic successive transfers of the glycerol-converting enrichment culture, combined with serial dilutions were performed. After eight generations a highly enriched, low diversity (microscopic observations and 16s rRNA DGGE profiling) microbial culture was obtained.

### **Conclusions**

The enriched culture converted glycerol mainly to methane (6mM) and acetate (7mM) within 6 days of incubation. A yet unknown organic compound was also produced. Sequencing results obtained on the Illumina platform showed the bacterial predominance of an uncultured *Thermotoga* species (75 % of the retrieved sequences), an uncultured *Anaerobaculum* species (13 %) and a close relative to *Thermoanaerobacter pseudethanolicus* (5 %). Isolation of the new uncultured *Thermotoga* and *Anaerobaculum* species is ongoing and their role in glycerol degradation will be assessed.

**SIMULTANEOUS AND SEPARATED SACCHARIFICATION OF BANANA PSEUDO-STEM WASTE (MUSA X PARADISIACA VAR. SAPIENTUM L.) AND FERMENTATION OF THE HYDROLYSATE USING MICROBE CONSORSIUM FOR BIOETHANOL PRODUCTION**

*R. Safitri<sup>1</sup>, M. Nurzaman<sup>1</sup>, K. Lubiana<sup>1</sup>*

*<sup>1</sup>Biology, Universitas Padjadjaran, Bandung, Indonesia*

**Background**

*Bioethanol fermentation can using the high cellulose substrat such as banana pseudo-stem that has 35,96% of cellulose content. The research about simultaneous and separated saccharification of banana pseudo-stem waste (Musa x paradisiaca var. sapientum L.) and fermentation of the hydrolysate for bioethanol production to get an effective enzyme dosage of hydrolysis , consortium of microbes, method of fermentation has been carried out.*

**Objectives**

The purpose of the research are to get the most effective concortium and method in bioethanol fermentation from banana pseudo-stem waste (*Musa x paradisiaca var. sapientum L.*) using *Simultaneous Saccharification and Fermentation* (SFS) and *Saparated Hydrolisis and Fermentation* (SHF) methods.

**Methods**

*The experimental method was used in fermentation process of banana pseudo-stem waste with Complete Randomize Design (CRD) consist of 2 factors and 3 replications. First factor were the combination of method and consorsium (K) and second factor were sampling time (T).*

**Conclusions**

*The result showed that the most effective dosage during dosage optimization of  $\alpha$ -amylase enzyme was dosage 1 with Dextrose Equivalent (DE) about 23,1; hemicellulase enzyme was dosage 2/3 with DE about 34,9; cellulase enzyme and glucoamylase enzym were dosage 2/3 with DE about 57,4. The result showed that concortium of *Pichia stipitis* and *Saccharomyces cerevisiae* and *Simultaneous Saccharification and Fermentation* (SFS) method were the best concortium and method in bioethanol fermentation of banana pseudo-stem waste that produce the highest ethanol concentration about 6,376% in 72 hours fermentation.*

#### **ISOLATION OF THERMOPHILIC BACTERIA FROM VINASSE OF SUGAR CANE**

F. Saia<sup>1</sup>, E.L.E.N. Perpetuo<sup>1</sup>, P. Eloisa<sup>2</sup>, D. Kamida<sup>3</sup>

<sup>1</sup>*Marine Science, Federal University of Sao Paulo, Santos, Brazil*

<sup>2</sup>*Environmental Engineering, EESC-USP, Sao Carlos, Brazil*

<sup>3</sup>*Science Marine, Federal University of Sao Paulo, Santos, Brazil*

#### **Background**

Vinasse is a liquid by-product of the ethanol production. Its high organic content (COD of 20-40g/L) means that its disposal into the environment is hazardous and has a considerable pollution potential. However, vinasse can be treated by fermentation process in bioreactors. In this case, thermophilic anaerobic digestion can be used to treat this wastewater from sugar cane industry.

#### **Objectives**

The aim of this work was to isolate thermophilic fermentative bacteria present in vinasse.

#### **Methods**

Thermophilic bacteria was isolated by anaerobic serial dilution technique on plates containing fermented vinasse with pH of 6,5 and at 50°C. Colonies were identified by MALDI-TOF mass spectrometry technique.

#### **Conclusions**

*Bacillus thermoamylovorans*, facultatively anaerobic and amylolytic bacterium was isolated from fermented vinasse. This strain ferments carbohydrate producing lactate, acetate, ethanol, and formate but not hydrogen (Combet-Blanc et al, 1995). The presence of this bacterium shows that vinasse is a source of microorganisms that can be used as inocula in anaerobic treatment of vinasse.

#### **ENDO-BETA-1,4-MANNANASES FROM THERMOTOLERANT BACILLUS SP.**

W. Seesom<sup>1</sup>, T. Sakamoto<sup>2</sup>, P. Thongket<sup>1</sup>, W. Sukhumsirichart<sup>1</sup>

<sup>1</sup>*Department of Biochemistry Faculty of Medicine, Srinakharinwirot University, Bangkok, Thailand*

<sup>2</sup>*Division of Applied Life Sciences Graduate School of Life and Environmental Sciences, Osaka Prefecture University, Osaka, Japan*

#### **Background**

Endo- $\beta$ -1,4-mannanases are important catalytic agent in several industries. The enzymes randomly cleave the  $\beta$ -1,4-linkage in mannan backbone and release short  $\beta$ -1,4-mannooligosaccharides and mannose. They are classified as glycoside hydrolases.

#### **Objectives**

The present study, the endo- $\beta$ -1,4 mannanase was isolated from thermotolerant bacteria and physicochemistry properties of purified enzyme were characterized.

#### **Methods**

Microorganisms (320 isolates) were screened on minimum medium containing locust bean gum at 45°C. The species of selected strain was identified by 16S rDNA sequence analysis. An endo- $\beta$ -1,4-mannanase was purified to homogeneity by using anion-exchange, hydrophobic, and size-exclusive column chromatographies. The molecular mass was analyzed by SDS-PAGE.

#### **Conclusions**

The 16S rDNA sequence revealed that the highest mannanase producing microorganism was *Bacillus* sp. The specific activity of purified enzyme was 14.5 U/mg. The apparent molecular mass was 38 kDa. The optimal pH and temperature for enzyme activity were pH 6.0 and 60°C, respectively. The enzyme was stable in a pH ranges from 5 to 9, after 16 h of incubation at 4°C and stable up to 60°C for 1 h, and more than 80 % of initial activity remained. This endo- $\beta$ -1,4-mannanase can be applied in several industries such as animal feed, pharmaceutical, paper and pulp, coffee, and bioethanol.

## **ESCHERICHIA COLI [NI-FE]-HYDROGENASES ACTIVITY DURING GLYCEROL FERMENTATION UPON FORMATE SUPPLEMENTATION**

K. Trchounian<sup>1</sup>, A. Trchounian<sup>2</sup>

<sup>1</sup>Biophysics, Yerevan State University, Yerevan, Armenia

<sup>2</sup>Microbiology Plants & Microbes Biotechnology, Yerevan State University, Yerevan, Armenia

### **Background**

*Escherichia coli* encodes four [Ni-Fe]-hydrogenases (Hyd).

### **Objectives**

H<sub>2</sub> producing Hyd activity was studied during glycerol fermentation at different pHs upon external formate supplemented (10 mM).

### **Methods**

H<sub>2</sub> evolution was measured by using pair of Pt and Ti-Si redox electrodes.

### **Conclusions**

At pH 7.5 and 6.5 wild type cells showed similar H<sub>2</sub> production rate ( $V_{H_2}$ ) when in the assays glycerol was added, whereas in formate supplemented assays it was decreased ~1.5 fold at pH 6.5.  $V_{H_2}$  was lowered ~2 fold in *selC* (coding for formate dehydrogenases) single mutant at pH 7.5. At both pHs when formate was added in the assays,  $V_{H_2}$  decreased in the strains where Hyd-3 or formate hydrogen lyase 1 related enzymes were disturbed. When glycerol was supplemented in the assays,  $V_{H_2}$  was significantly lowered in triple *hyaB hybC* (coding for large subunits of Hyd-1 and Hyd-2, respectively) *selC* or *hyaB hybC hycE* (coding for large subunit of Hyd-3) mutants at both pHs.

Taken together it might be suggested that Hyd-3 becomes mainly responsible for H<sub>2</sub> production during glycerol fermentation when external formate is added. Besides, in the glycerol supplemented assays, three hydrogenases can work in H<sub>2</sub> producing mode and only deletion of three of them decreases the production of H<sub>2</sub>. This effect might be due to disturbance of H<sub>2</sub> cycling. Therefore, responsible Hyd enzymes have been revealed under the conditions above.

All this is of significance in application of different carbon sources, especially mixed carbons, in H<sub>2</sub> production technology using bacteria

#### **PURIFICATION OF FERULIC ACID ESTERASE FROM BACILLUS MEGATERIUM**

*K. Woranuch<sup>1</sup>, T. Sakamoto<sup>2</sup>, W. Sukhumsirichart<sup>1</sup>*

<sup>1</sup>*Biochemistry, Srinakharinwirot University, Bangkok, Thailand*

<sup>2</sup>*Applied Life Sciences Graduate School of Life and Environmental Sciences,  
Osaka Prefecture University, Osaka, Japan*

#### **Background**

Ferulic acid esterase (FAE) are a subclass of carboxylic acid esterases (EC 3.1.1.73) that play role in complete enzymatic hydrolysis of hemicelluloses by hydrolyzing the ferulate ester groups in the cross-linking between hemicelluloses and between hemicellulose and lignin.

#### **Objectives**

To screen and purify ferulic acid esterase from thermotolerant bacteria

#### **Methods**

A total of 250 microorganisms collected from soil and rotten wood were isolated on minimum medium containing 1% rice straw at 45°C for strains that produced high FAE activity. The selected isolate was identified by 16S rDNA sequence analysis. Enzyme was purified by using anion-exchange, hydrophobic, and size-exclusive column chromatographies. The purified enzyme was characterized for its temperature and pH optima and stability.

#### **Conclusions**

The 16S rDNA analysis of selected isolate revealed that it belong to *Bacillus megaterium*. The optimum temperature and pH of purified FAE were 60°C and pH 7.0. The enzyme was stable in a wide pH ranges (pH 1–8), more than 80 % of initial activity remained after 16 h of incubation at 4 °C and stable up to 80°C for 1 h. The specific activity was 298.01 U/mg. This ferulic acid esterase have potential applications for several industries that high temperature and wide pH range are needed.

<sup>2</sup>*Orchard Management and Nutrition Laboratory of Rhizosphere, Research Institute of Horticulture, Skierniewice, Poland*

<sup>3</sup>*Faculty of Agriculture and Biology Department of Biology of Microorganisms, Warsaw University of Life Sciences, Warsaw, Poland*

**Background**

Phosphogypsum and sewage sludge are formed as a by-product during production of fertilizers from phosphate rock and industrial or municipal waste-water treatment, respectively.

**Objectives**

The aim of present study was to investigate the hemp yield and arbuscular mycorrhizal fungi (AMF) root colonization and spore formation in response to phosphogypsum and municipal sewage sludge fertilization. Additionally the effect of phosphogypsum and sewage sludge on soil respiration, microbial biomass and dehydrogenase activity were also examined.

**Methods**

The field spots with three hemp varieties Beniko, Białobrzeskie and Tygra were studied. An equivalent of 170 kg per ha pure nitrogen was used as fertilization in treatments with sewage sludge. The phosphogypsum at the level 100, 500 and 1000 kg per ha was applied.

AMF root colonization by microscopic and molecular techniques were studied. For determination of soil microbial biomass fumigation-extraction method (PN-ISO 14240-2) was used. Soil respiration by determination of CO<sub>2</sub> release by titration (PN-ISO 16072) and dehydrogenase activity by TTC method (PN-ISO 23753-1) were measured.

**Conclusions**

Application in agriculture seems to be one of the most reasonable possibility for utilization of phosphogypsum and sewage sludge, especially as fertilizer in energetic plant production. Additionally, phosphogypsum in combination with sewage sludge significantly increased soil biological activity.

Financial support was provided by EU Project at Warsaw Life Sciences University 'A program to improve the level of the didactic approach to the question of how to obtain raw plant materials for the purposes of energy production in the context of the Europe 2020 Strategy objectives'.

<sup>2</sup>BIOCANT, Microbiology Unit BIOCANT, Cantanhede, Portugal

<sup>3</sup>CNR, Institute for Coastal Marine Environment, Messina, Italy

<sup>4</sup>University of Coimbra, Department of Life Sciences, Coimbra, Portugal

**Background**

Three strains designated 221-F1<sup>T</sup>, 221-F2 and 3030-F1 were isolated from the Matapan Vavilov Deep canyon, also known as Calypso Deep in the Eastern Mediterranean Sea, at a depth of 4,908 meters.

**Objectives**

To describe a new species based on 16S rRNA gene sequence analysis and phenotypic characteristics. These strains were found to be most closely related to *Palleronia marisminoris* and *Hwanghaeicola aestuarii*.

**Methods**

The description is based on a polyphasic approach with extensive phenotypic, quimiotaxonomic, genotypic and phylogenetic analysis.

**Conclusions**

The strains were observed to be red-pigmented and to form non-motile cocci or pleomorphic cells. The cells were found to stain Gram-negative, to be strictly aerobic, oxidase and catalase positive. Strains 221-F1<sup>T</sup>, 221-F2 and 3030-F1 were found to be mesophilic and to grow in medium containing up to 13 % NaCl. The major polar lipids of the three strains were identified as diphosphatidylglycerol, phosphatidylglycerol, phosphatidylcholine, an unidentified glycolipid and an unidentified aminolipid. Ubiquinone 10 (U-10) was found to be the major respiratory quinone. The DNA G+C content of strain 221-F1<sup>T</sup> was determined to be 64.7 mol %. The new isolates were unambiguously more closely related to the type strain of *Palleronia marisminoris* (95.3% of similarity) than to *Hwanghaeicola aestuarii* (94.7% of similarity). Based on phylogenetic, physiological and biochemical characteristics we describe a new species represented by strain 221-F1<sup>T</sup> (=CECT 8504<sup>T</sup> =LMG 27977<sup>T</sup>) for which we propose the name *Palleronia abyssalis* sp. nov. We also propose to emend the description of the genus *Palleronia* and the species *Palleronia marisminoris* to reflect new results obtained in this study.

<sup>2</sup>Laboratoire de Chimie Bactérienne, CNRS, Marseille, France

<sup>3</sup>Institut Méditerranéen d'Océanologie, Aix-Marseille Université, Marseille, France

<sup>4</sup>Faculty of Biology Department of Microbiology,  
Lomonosov Moscow State University, Moscow, Russia

### **Background**

The Black Sea is a world's largest meromictic basin, where deep sulfide-rich waters do not mix with the upper oxic waters. Interestingly, sulfate-reducing bacteria (SRB) were detected there not only in the anoxic zone but also in the oxic water layer. A pure culture of a new SRB species, possessing different systems of antioxidative defense, was isolated for the first time from the Black Sea oxygenated water column.

### **Objectives**

We analyzed the phylogenetic composition of SRB community in the Black Sea oxic waters where representatives of *Desulfovibrio-Desulfomicrobium*, *Desulfococcus-Desulfonema-Desulfosarcina* and *Desulfotomaculum* subgroups were revealed. The pure culture of psychrophilic Gram-negative SRB was isolated from the subsurface oxic waters and described as *Desulfofrigus euxinos*. This new species possesses different systems of antioxidative defense including O<sub>2</sub> reduction and ROS detoxification.

### **Methods**

FISH, nested and qRT-PCR with primers to 16S rRNA and *dsrB* genes, DGGE and nucleotide sequencing were used to investigate the SRB community. DNA-DNA hybridization, fatty acids analysis and growth tests with different electron donors/acceptors were performed to characterize the SRB species. Oxygen consumption rates were measured with a Clark-type electrode. Key genes of antioxidative defense were identified by DOP-PCR, and inverse PCR was carried out for the sequence analysis of the entire genes.

### **Conclusions**

While some SRB are resistant to aerobic conditions because of multi-component antioxidative mechanisms, their presence in the sea oxygenated waters is likely to depend also on inhabiting anoxic microniches within suspended organic particles. The work was supported by RFBR projects nos. 10-04-00220-a and 12-04-91052-CNRS-a (PICS #6041).

## **SPATIO-TEMPORAL DYNAMICS OF BACTERIAL COMMUNITIES IN A STRATIFIED LAKE**

M. Diao<sup>1</sup>, R. Sinnige<sup>1</sup>, K. Kalbitz<sup>2</sup>, J. Huisman<sup>1</sup>, G. Muyzer<sup>1</sup>

<sup>1</sup>*Aquatic Microbiology, University of Amsterdam, Amsterdam, Netherlands*

<sup>2</sup>*Soil Resources and Land Use, Technical University of Dresden, Dresden, Germany*

### **Background**

Bacteria play an essential role in food webs and biogeochemical cycles in aquatic ecosystems. Investigating ecological relationships among bacterial taxa and between abiotic and biotic ecosystem components is critical to environmental control and functional traits of individual bacterial group. However, such information is scarce. Here we present the results of a study on the spatio-temporal dynamics of bacterial communities in a stratified lake.

### **Objectives**

The main objectives of the present study were to: (a) investigate the bacterial diversity and dynamics through time and space; (b) identify relations between specific bacterial groups and environmental parameters.

### **Methods**

We collected over a year monthly samples throughout the water column and from the sediment of a holomictic lake in the Netherlands. Subsequently, we sequenced the 16S rRNA genes of bacteria on an Illumina MiSeq platform to determine the diversity and relative abundance. Simultaneously different physical and chemical parameters were measured. Statistical analysis was performed to detect possible interactions among different populations and to determine relations between specific bacterial groups and environmental parameters.

### **Conclusions**

All sequences were affiliated to members of phyla commonly found in freshwater systems. Bacterial community changed dramatically over time and space in the water column, but clear seasonal successions could be observed. Contrastingly, the bacterial community in the sediment was quite stable, and mainly composed of *Proteobacteria* and *Bacteroidetes*. Statistical analysis showed *Actinobacteria* were positively correlated with temperature, while *Cyanobacteria* and *Planctomycetes* co-varied with nitrate. *Betaproteobacteria*, *Deltaproteobacteria*, *Gammaproteobacteria*,

*Epsilonproteobacteria* and *Firmicutes* were positively correlated with ammonium and negatively correlated with dissolved oxygen and pH.

<sup>2</sup>*Departament of Biology, University of Playa Ancha, Valparaiso, Chile*

<sup>3</sup>*Marine Quintay Research Center, Andrés Bello National University, Quintay, Chile*

<sup>4</sup>*Fish and Isotope Ecology Laboratory Instituto de Ciencias Naturales Alexander Von Humboldt, University of Antofagasta, Antofagasta, Chile*

**Background**

The high-altitude wetlands of the Chilean Altiplano (Atacama Desert) are unique and remote aquatic ecosystems, and are considered part of the cold biosphere. These ecosystems characteristically contain organisms with a high level of endemism that can prosper under extreme environmental conditions. Furthermore, microbial diversity is typically high, and includes a large contribution of previously undescribed groups of Bacteria and Archaea. Microbial mats are common, but are typically small in area and depth relative to those described from other environments.

**Objectives**

To describe members of the rare biosphere from a micro-profile taken from Salar de Huasco microbial mat.

**Methods**

Bacterial diversity was described by pyrosequencing of 16S rRNA genes of each layer (5) of a microbial mat (<5 mm depth) as well as metagenomic analysis (454 Roche) of microbial mat samples. Oxygen microprofiles were performed *in situ* using a microprofiling system (Unisense). Microbial diversity was characterized by the presence of groups of low relative abundance (rare biosphere) and also low sequence identity with sequences of available databases. At the phyla level, rare bacteria from the microbial mats (1.6-0.05% of relative abundance) were affiliated with *Planctomycetes*, *Verrucomicrobia*, *Chlorobi*, *Acidobacteria*, SR1, *Armatimonadetes* (ex-OP10), OD1, BRC1, *Saccharibacteria* (ex-TM7), OP11, *Lentisphaerae*, *Spirochaetes*, *Synergistetes*, and others.

**Conclusions**

Different members of the rare biosphere were present across the microbial mat micro-profile. Particular rare groups could be associated with the specific conditions in each layer of the microbial mat, providing clues to their likely metabolic function.

**Microbiology of aquatic ecosystems**

**MICROBIAL COMMUNITIES IN OPERATIONAL DRINKING WATER  
DISTRIBUTION SYSTEMS: IMPLICATIONS FOR DRINKING WATER QUALITY**

*I. Douterelo<sup>1</sup>, M. Jackson<sup>2</sup>, J.B. Boxall<sup>1</sup>*

*<sup>1</sup>Civil and Structural Engineering, The University of Sheffield, Sheffield,  
United Kingdom*

*<sup>2</sup>Wessex Water, Claverton Down Rd, Bath, United Kingdom*

**Background**

Microorganisms inhabiting drinking water distribution systems (DWDS), particularly those attached to pipes forming biofilms, can affect the safety and quality of the water. The presence of unfavourable microorganisms in DWDS is influenced by a number of factors ranging from physico-chemical properties of the source water to the characteristics of the pipe infrastructure itself. The difficulty of accessing the internal surface of pipes has limited the study of the microbial ecology of DWDS. Most previous research in this area has been based on laboratory models and/or assessing only few selected microorganisms under controlled conditions which do not represent real systems.

**Objectives**

To better understand the microbial ecology of DWDS, microbial communities were monitored in two chlorinated networks supplied with different source waters.

**Methods**

Biofilm sampling devices fitted with coupons designed to maintain boundary layer conditions at the pipe water interface were installed in the networks. Over a one year-period, water physico-chemical parameters were measured and the dynamics of plankton and biofilm communities were monitored using Illumina MySeq sequencing.

**Conclusions**

Clear differences in the composition of the microbial communities supplied with different source waters were detected. Microbial diversity in the groundwater supplied network was higher than previously thought in chlorinated systems. Source water and the hydraulic regime in the system were critical factors shifting microbial communities and influencing the quality of the water. This new understanding of the microbial ecology of DWDS is vital to improve control and management strategies to help safeguard drinking water quality and ultimately public health.

**CYTOTOXIC AND ANTIMICROBIAL ACTIVITIES OF SECONDARY METABOLITES PRODUCED BY MARINE ACTINOMYCETE STRAINS ISOLATED FROM SAUDI COASTAL HABITATS**

W.N. Hozzein<sup>1</sup>, S.M.H. Khalaf<sup>1</sup>, E.A. Elsayed<sup>1</sup>, M.A.M. Wadaan<sup>1</sup>

<sup>1</sup>Zoology Department, College of Science King Saud University, Riyadh, Saudi Arabia

**Background**

Cancer and infectious diseases are still the main two health problems facing the humankind. Actinomycetes from the coastal habitats of Saudi Arabia can represent a good source for drug discovery.

**Objectives**

The main objectives of the present study were screening the marine actinomycete strains isolated from the coastal habitats of Saudi Arabia for production of anticancer and antimicrobial compounds and identifying them to the species level by the polyphasic approach.

**Methods**

Eight samples were collected from the Arabian Gulf habitats of Saudi Arabia. The selective isolation of actinomycetes was carried out on three different recommended media. Twenty six strains were selected to study their diversity by examining their morphology and determining their cell wall diaminopimelic acid type and whole-cell sugar pattern. Sixteen representative strains were screened for their cytotoxic and antimicrobial activities and their taxonomic positions were confirmed by the phylogenetic analysis of the 16S rRNA gene sequence.

**Conclusions**

Based on dissimilarities in their appearance on two media, twenty six strains were selected and primarily assigned to 8 actinomycete genera; *Micromonospora*, *Streptomyces*, *Nocardiopsis*, *Amycolatopsis*, *Microtetraspora*, *Nonomuraea*, *Actinopolyspora* and *Saccharomonospora*. These results showed that there is good actinomycete genus diversity in the Saudi coastal habitats. Out of the selected sixteen strains, seven strains showed promising activity against the tested Gram-positive, Gram-negative bacteria and yeast strains. In addition, the actinomycete extracts showed potent anticancer activities against human T cell leukemia (Jurkat) and human laryngeal carcinoma (Hep-2) cell lines. The results are encouraging as novel strains have been isolated and identified and the active secondary metabolites are promising.

**MICROBIAL IRON CYCLING IN COASTAL MARINE SEDIMENTS –  
COMPETITION AND INTERRELATION OF FE(II)-OXIDIZERS AND FE(III)-  
REDUCERS**

K. Laufer<sup>1</sup>, C. Schmidt<sup>1</sup>, S. Behrens<sup>1</sup>, B.B. Jørgensen<sup>2</sup>, A. Kappler<sup>1</sup>

<sup>1</sup>Geomicrobiology, University of Tübingen, Tübingen, Germany

<sup>2</sup>Center for Geomicrobiology, Aarhus University, Aarhus, Denmark

**Background**

Iron is an abundant redox-active element in many environments and iron(III)-reducing and iron(II)-oxidizing bacteria are largely responsible for microbial iron redox cycling. Three metabolic types of neutrophilic Fe(II)-oxidizing bacteria are known, i.e. microaerophilic, nitrate-reducing, and phototrophic Fe(II)-oxidizers. Based on the geochemical conditions in redox-stratified marine sediments, all three can potentially co-exist with overlapping niches.

**Objectives**

Consequently, there is potential for competition for their electron donor, Fe(II), that is formed by Fe(III)-reducing microorganisms which can interact with the iron-oxidizing microbial community. However, most studies of iron cycling have so far focused only on a single metabolic type of iron(II) oxidation coupled to iron(III) reduction.

**Methods**

In our study, we therefore determined the spatial distribution of the different metabolic types of iron-oxidizing and iron-reducing bacteria along the steep redox gradients within a coastal marine sediment from Aarhus Bay, Denmark, by MPN studies, isolations and qPCR. Furthermore, the iron(II)-oxidizing and iron(III)-reducing activity of the different metabolic types and their potential contribution to iron mineral formation within the sediment were quantified by microcosm studies.

**Conclusions**

From our results we conclude that microbial iron cycling occurs in these sediments and involves microaerophilic, phototrophic and nitrate-reducing Fe(II)-oxidizers as well as Fe(III)-reducers. The quantification of rates of iron oxidation and reduction under dynamic environmental conditions, including day-night cycles, input of nitrate or O<sub>2</sub>, reveals the competition and ecological network of iron-oxidizing and -reducing bacteria and is an essential step in order to evaluate the importance of microbial iron cycling in coastal marine sediments.

**DIVERSITY AND BIOSYNTHETIC POTENTIAL OF CULTURABLE YELLOW-PIGMENTED BACTERIA ASSOCIATED WITH THE SURFACE OF ANTARCTIC MACROALGAE**

S. Leiva<sup>1</sup>, P. Alvarado-Wevar<sup>1</sup>, I. Garrido<sup>2</sup>, M.J. Díaz<sup>2</sup>, J. Holtheuer<sup>2</sup>

<sup>1</sup>*Instituto de Bioquímica y Microbiología. Facultad de Ciencias., Universidad Austral de Chile. Campus Isla Teja. Casilla 567., Valdivia, Chile*

<sup>2</sup>*Instituto de Ciencias Marinas y Limnológicas. Facultad de Ciencias., Universidad Austral de Chile. Campus Isla Teja. Casilla 567., Valdivia, Chile*

**Background**

Algal surfaces are an untapped source of microbial diversity and could represent a promising source of novel therapeutic agents. Very little is known about the diversity and bioactive potential of Gram-positive bacteria associated with the surface of Antarctic macroalgae. Furthermore, it remains unclear the natural distribution, diversity and ecological contributions of Antarctic pigmented heterotrophic bacteria. To our best knowledge, this study is the first research carried out on the diversity and biosynthetic potential of pigmented bacteria associated with Antarctic macroalgae.

**Objectives**

This study aims to explore the phylogenetic diversity and potential to produce secondary metabolites of Gram-positive, yellow-pigmented bacteria isolated from the surface of intertidal and subtidal Antarctic macroalgae.

**Methods**

Representative species of green, red and brown algae were collected from the intertidal and subtidal zone (5 and 30 m) of King George Island, Antarctica, in January 2014. Surface-associated bacteria were investigated by cultivation-based methods and 16S rRNA gene sequencing. Yellow-pigmented isolates were screened for the presence of genes encoding polyketide synthases (PKS) by PCR amplification with degenerate primers.

**Conclusions**

The phylogenetic analysis showed that the yellow-pigmented epibionts belonged to the genera *Arthrobacter*, *Citricoccus*, *Kocuria*, *Labeledella*, *Microbacterium*, *Salinibacterium* and *Staphylococcus*. PKS sequences were detected in *Kocuria* and *Staphylococcus* isolates. It highlights that Antarctic macroalgae are a unique source of microbial diversity for natural product research.

**STUDYING THE GREAT POTENTIAL OF CULTIVABLE BACTERIAL  
COMMUNITIES ASSOCIATED WITH THE BROWN ALGA ASCOPHYLLUM  
NODOSUM**

M. Martin<sup>1</sup>, R. Martin<sup>1</sup>, T. Barbeyron<sup>2</sup>, D. Portetelle<sup>1</sup>, G. Michel<sup>2</sup>, M. Vandenberg<sup>1</sup>

<sup>1</sup>Microbiology and Genomics, Gembloux Agro Bio Tech (ULg), Gembloux, Belgium

<sup>2</sup>UMR 8227 Integrative Biology of Marine Models,

CNRS- UPMC- Station Biologique de Roscoff, Roscoff, France

**Background**

Bacteria associated with algae differ markedly from those living freely in seawater and represent great potential for the production of diverse bioactive compounds as they interact in multiple complex ways with their host.

**Objectives**

This work aims to study cultivable bacteria associated with the brown alga *Ascophyllum nodosum*, showing polysaccharolytic activities.

**Methods**

To isolate cultivable microorganisms, algal thalli of *Ascophyllum nodosum* were swabbed with sterile cotton tips and marine agar plates were inoculated. Three-hundred isolated bacteria were screened for agarase, kappa- or iota-carrageenase activities on specific marine media. Thirty-two bacteria with polysaccharolytic activities were isolated and a part of their 16S rDNA (8F-1492R) were amplified and sequenced. Twenty-seven were classified as *Flavobacteriia* and five as *Gammaproteobacteria*. Putative new strains and species of *Zobellia*, *Maribacter*, *Cellulophaga*, *Shewanella*, *Glaciecola*, *Pseudoalteromonas* and *Colwellia* were identified by phylogenetic analysis. Genomics libraries with their DNA were constructed in *Escherichia coli* and *Bacillus subtilis* and are currently screened for diverse enzymatic activities (agarases, iota-and kappa-carrageenases, cellulases, beta-glucosidases, sulfatases and amylases).

**Conclusions**

In an era where high throughput sequencing is mostly used to study bacterial communities, cultivation methods are underestimated. Here, we revealed that only ten percent of the cultivable bacteria on this brown alga could degrade algal polysaccharides, which lead to asking us; who and what are the 90 other percents doing there? Furthermore, by this cultivation method we could also identify putative new bacterial strains/species, which are screened for polysaccharidases. Novel glycoside hydrolases from unknown marine bacteria represent great biotechnological potential as they should have original industrial properties.

**COMBINING MORPHOLOGICAL, BIOCHEMICAL AND PHYSIOLOGICAL ASPECTS TO COMPARE TWO STRAINS OF MICROCYSTIS AERUGINOSA (CYANOBACTERIA) DIFFERING IN THE PRODUCTION OF MICROCYSTIN**

A. Pacheco<sup>1</sup>, F.R. Jacinavicius<sup>2</sup>, C.L. Sant'Anna<sup>2</sup>

<sup>1</sup>*Biophysics Institute, Federal University of Rio de Janeiro, Rio de Janeiro, Brazil*

<sup>2</sup>*Nucleus of Phycology, Institute of Botany, São Paulo, Brazil*

**Background**

*Microcystis aeruginosa* is a bloom forming cyanobacteria impacting freshwater environments worldwide. Blooms are formed by a mix of strains, some able to produce a hepatotoxic peptide called microcystin, others not.

**Objectives**

Our objective was to compare two *M. aeruginosa* strains, a microcystin producing and a non producing one, isolated from reservoirs in São Paulo, Brazil.

**Methods**

The strains were cultured (23±2 °C, 40-50 μmol photons m<sup>-2</sup>.s<sup>-1</sup>, 14-10h light–dark cycle, ASM-1 medium), cells collected at exponential growth phase and morphological and physiological aspects were investigated. Proteomic shotgun analysis was performed using iTRAQ and 2DLC-MS/MS.

**Conclusions**

The strains were similar in chlorophyll-a and phycocyanin content, the non toxic strain had higher carotenoid content. The toxic strain was richer in antioxidants. It formed floating colonies with numerous cells embedded in mucilage (diameter 150-800μm). In contrast, the non toxic strain exhibited small colonies (100μm) with few cells dispersed in thick mucilage, not floating. Electronic microscopy revealed thylakoids and polyphosphate granules equally present in both strains, aerotopes more abundant in the toxic one, cyanophycin granules and carboxysomes more evident in the non toxic strain. Sixty nine differentially expressed proteins were found. Both strains expressed proteins related to photosynthesis, energy metabolism and translation. Gas vesicle and stress response proteins were more abundant in the toxic strain while transport and protein folding functions were more expressed in the non toxic one. These results are discussed in relation to the other physiological aspects investigated. These differences probably represent distinct ecological strategies adopted by each strain.

**Microbiology of aquatic ecosystems**

**BIODEGRADATION OF MICROCYSTIN-LR BY BACTERIA FROM THE SEDIMENT OF JACAREPAGUA LAGOON (RIO DE JANEIRO, BRAZIL)**

A. Pacheco<sup>1</sup>, A. Amorim<sup>1</sup>, V.F. Magalhães<sup>1</sup>

<sup>1</sup>*Biophysics Institute, Federal University of Rio de Janeiro, Rio de Janeiro, Brazil*

**Background**

The release of effluents into aquatic systems leads to an increase in nutrients, a process known as eutrophication. This process promotes large proliferations of cyanobacteria (blooms) that can be harmful to the environment and to humans due to the production of cyanotoxins. The cyclic peptide microcystin (MC) is the prevalent and most studied cyanotoxin in blooms, with more than 80 variants. It has been reported consistently since 1996 in Jacarepagua Lagoon (RJ). MC is rarely found dissolved in the water column, but adsorbs to particles in suspension which settle at the bottom sediment or undergo biodegradation by microorganisms.

**Objectives**

The objective of this study was to evaluate the potential for biodegradation of MC-LR by bacteria found in the lagoon sediment, testing both recently isolated strains and microbial assemblages.

**Methods**

MC-LR was incubated with isolated strains (15) or microbial assemblages for 1 and 7 days, and quantified by LCMS.

**Conclusions**

After 7 days only one strain showed degradation of MC. The microbial assemblage extracted directly from the sediment was very efficient in degradation, decreasing (by ~50%) the added MC. Part of the observed decrease in MC amount was recognized as adsorption to sediment particles. The 15 isolated strains were identified as *Ralstonia* or *Bacillus* by 16SrDNA sequencing. This indicated that the culture medium led to selection of microorganisms, probably eliminating those able to degrade MC. On the other hand, MC degradation by microbial assemblages reflects the metabolic diversity of this sample and points to a possible cooperative activity to complete the process of biodegradation.

University of Patras, PATRA, Greece

<sup>3</sup>Department of Molecular Biology and Genetics, Democritus University of Thrace,  
Alexandroupoli, Greece

<sup>4</sup>Department of Medical Laboratories, Technological Educational Institute of Athens,  
Athens, Greece

**Background**

Recent isolation of *Ps. aeruginosa* strains from Greek aquatic environments and subsequent PFGE analysis demonstrated that these strains have a unique genotype. Environmental isolates may also have a unique phylogenetic position. Literature has revealed that the behavior of *Ps. aeruginosa* during typing is affected by its habitat and by stress factors such as antibiotics, biofilm formation e.t.c.

**Objectives**

Considering the advantages of MLST, as a typing method that focuses strictly on 7 conserved housekeeping genes, it was chosen for typing and discrimination of *Ps. aeruginosa* strains isolated from water samples from all over Greece. Additional information regarding the resistant phenotypes circulating in these environments is cited.

**Methods**

The activity of 14 antibiotics was tested against all isolates by the disk diffusion method, where additional phenotypical tests were performed according to published protocols. MLST was performed as described by Curran et al, 2004 with some alterations concerning the annealing temperatures of the seven housekeeping genes. The control strains *Pseudomonas aeruginosa* ATCC 27853, clinical control from HPA/NEQAS (External Quality Control) and PAO1 were used as standards of reference during the MLST and for reproducibility experiments.

**Conclusions**

The majority of the isolates exhibited the intrinsic antimicrobial resistance, while a significant proportion presented additional resistant mechanisms. The amended protocol of MLST seemed to produce allelic profiles for all the isolates so far tested. Thus this typing method is going to be used in a larger sampling program to obtain more data and to conclude in a reliable phylogenetic analysis for the first time in aquatic environments of Greece.

**PHOTOCHEMICAL AND MICROBIAL ALTERATIONS OF DOM SPECTROSCOPIC PROPERTIES IN THE ESTUARINE SYSTEM RIA DE AVEIRO**

L. Santos<sup>1</sup>, E.B.H. Santos<sup>2</sup>, A. Cunha<sup>1</sup>, A. Almeida<sup>1</sup>

<sup>1</sup>*Department of Biology & CESAM, Universidade de Aveiro, Aveiro, Portugal*

<sup>2</sup>*Department of Chemistry & CESAM, Universidade de Aveiro, Aveiro, Portugal*

**Background**

Photochemical transformations of chromophoric dissolved organic matter (CDOM) influence microbial communities in aquatic systems.

**Objectives**

This work aimed to evaluate this influence in the estuary Ria de Aveiro. In order to achieve that, two sites representative of the marine (MZ) and brackish water (BZ) zones of the estuary were regularly surveyed.

**Methods**

Optical parameters of CDOM indicative of aromaticity and molecular weight were used to establish CDOM sources, and microbial abundance and activity was characterized. Additionally, microcosm experiments were performed in order to simulate photochemical reactions of CDOM and to evaluate microbial responses to changes in CDOM composition.

**Conclusions**

The CDOM of the two zones showed different spectral characteristics, with significantly higher values of the specific ultra-violet absorbance at 254 nm and of the absorption coefficient at 350 nm and lower SR ratio at BZ than at the MZ, reflecting the different amounts and prevailing sources of organic matter, as well as distinct riverine and oceanic influences. At the MZ, the abundance of bacteria and the aminopeptidase activity correlated with absorbance, suggesting a microbial contribution to the HMW CDOM pool. The irradiation of DOM resulted in loss of color and increase of its bioavailability. However, the extent of photoinduced transformations and microbial responses was dependent on the initial characteristics of CDOM. In Ria de Aveiro both photochemical and microbial processes yielded optical changes in CDOM and the overall results of these combined processes determine the fate of CDOM in the estuary and have an influence on local productivity and in adjacent coastal areas.

**Microbiology of aquatic ecosystems**

**IN SITU DETECTION AND LOCALIZATION OF THE PROBIOTIC *PEDIOCOCCUS* SP. AB1 IN THE GUT OF ABALONE *HALIOTIS GIGANTEA***

R. Tanaka<sup>1</sup>, H. Mitsuya<sup>1</sup>, M. Aoki<sup>1</sup>, T. Miyazaki<sup>1</sup>, P. Bossier<sup>2</sup>

<sup>1</sup>Graduate School of Bioresources, Mie University, Tsu, Japan

<sup>2</sup>Laboratory of Aquaculture and Artemia Reference Center, Ghent University, Ghent, Belgium

**Background**

We previously reported that host-derived *Pediococcus* sp. Ab1 can colonize the gut of abalone *Haliotis gigantea* and that the addition of Ab1 to commercial feed can alter gut microflora and increase alginate lyase and VSCFAs in the gut. From those viewpoints, addition of Ab1 can provide valuable effects in abalone aquaculture as well as in other aquaculture animals.

**Objectives**

In this study, to revealing the dynamics of probiotic *Pediococcus* Ab1, we tried to establish an optimum FISH protocol, and tried to *in situ* detection of this bacterium.

**Methods**

TAMRA-labeled Rpt probe was constructed and samples were fixed by 4 % paraformaldehyde and hybridized at 40 °C for 3 h. In the case of described condition, we could discriminate clearly Ab1 from other control bacterial strains (*Enterococcus*, *Lactobacillus*). Fluorescence signals of Rpt probe-positive bacteria were easily distinguished from any detectable background autofluorescence.

**Conclusions**

Rpt probe-positive bacteria were detected in both probiotics supplemented animal and non-probiotics supplemented animal. Rpt probe-positive bacteria formed microbial colonies only in the probiotics supplemented animal. The mean numbers of Rpt probe-positive bacteria in the gut-attached samples of probiotic supplemented animal was  $1.94 \times 10^7$  cells/g-gut, and those of non-probiotic supplemented animal were  $6.85 \times 10^5$  cells/g-gut, respectively. From the thin section FISH analysis, Rpt positive cells were observed from gut samples of probiotics supplemented animal. Interestingly, Rpt positive cells were also observed from gills samples of them. From these results indicated that probiotic *Pediococcus* sp. ab1 is colonized and make a micro-colony in their host gut.

**REDUCTION OF BIOFILM FORMATION IN COOLING TOWER WATER SYSTEMS USING NANO-HYDROPHOBIC COATING**

I. Turetgen<sup>1</sup>, C. Vatansever<sup>1</sup>

<sup>1</sup>*Dept. of Biology, Istanbul University Faculty of Science, Istanbul, Turkey*

**Background**

The proposed study is to reduce biofilm formation using nano-hydrophobic coating on cooling tower fill materials. Consequently, enhancing cooling performance, lengthen the material life, reducing clogging and biofilm associated pathogen bacteria.

**Objectives**

Primary aim is to reduce the slimy biofilm formation on fill material, which will lead to better cooling of water, longer material life and less clogging of the fills. It is widely known that cooling towers' maintenance is heavily neglected. This end ups in shorter material life, expensive maintenance charges, inefficient cooling, excessive energy consumption and public health risk due to Legionella bacteria dissemination. While novel anti-biofilm approaches are still in nascent phases of development, our efforts are devoted for sustainable management of cooling towers and public health safety, where cooling towers are often associated with deadly Legionnaires' disease.

**Methods**

Test surfaces were placed into biofilm reactor along with the untreated control coupons up to 6-months period for biofilm maturation. Natural bacterial communities were monitored to analyze the impact to mimic the real-life conditions. Surfaces were monthly analyzed *in situ* for their microbial load using epifluorescence microscopy.

**Conclusions**

Wettability is known to play a key role in biofilm formation on surfaces, because characteristics of surface properties affect the bacterial adhesion. Results showed that surface-conditioning with nano-silica significantly reduce (up to 90%) biofilm formation. Easy coating process is a facile and low cost method to prepare hydrophobic surface without any kinds of expensive compounds or methods.

**THE REGULATION OF DIMETHYLSULFONIOPROPIONATE METABOLISM IN RUEGERIA POMEROYI DSS-3**

*H. Bullock*<sup>1</sup>, *A. Burns*<sup>2</sup>, *M. Moran*<sup>2</sup>, *W. Whitman*<sup>1</sup>

<sup>1</sup>*Microbiology, UGA, Athens, USA*

<sup>2</sup>*Marine Science, UGA, Athens, USA*

**Background**

Dimethylsulfoniopropionate (DMSP) plays a key role in the global sulfur cycle and marine microbial sulfur and carbon metabolism. The marine roseobacter *Ruegeria pomeroyi* DSS-3 is capable of metabolizing DMSP by either the cleavage or demethylation pathways. The cleavage pathway forms the volatile gas dimethylsulfide (DMS), the largest natural source of sulfur to the atmosphere. The demethylation pathway produces methanethiol (MeSH), which is readily assimilated or oxidized.

**Objectives**

A model for the regulation of DMSP metabolism has been developed for *R. pomeroyi* where the availability and turnover of methyl-tetrahydrofolate (THF) is a major regulatory point.

**Methods**

A combination of RNA-Seq, enzyme assays and growth experiments were performed to test predictions of the model.

**Conclusions**

According to RNA-Seq, the genes involved in THF biosynthesis and methyl-THF metabolism were significantly up-regulated during growth on DMSP as compared to acetate. Similarly, the specific activities of the methylene-THF reductase and formate dehydrogenase were two-fold higher in cell-free extracts of DMSP-grown cells. During growth on DMSP, treatment of cultures with low concentrations of the dihydrofolate reductase inhibitor trimethoprim increased production of DMS without inhibiting growth. This result was consistent with a model where high levels of methyl-THF metabolism allow DmdA to function at its maximal rate, leading to sufficient MMPA accumulation to overcome the DMSP-based inhibition of RPO\_DmdB2, one of the two isozymes for the second step in the pathway. Based on the current

knowledge of DMSP metabolism, the regulation of the two pathways in *R. pomeroyi* appears to be complex and multifaceted.

## **EFFECT OF BOTANICAL EXTRACTS & ESSENTIAL OILS IN FEED ON LAYING HENS PERFORMANCE & SALMONELLA, E.COLI & TOTAL BACTERIAL COUNT IN FECES**

A. Hasnain<sup>1</sup>, S. Waheed<sup>1</sup>, O. Mukhtar<sup>2</sup>, Z. Yaqeen<sup>3</sup>, S. Tehmina<sup>3</sup>

<sup>1</sup>Food Science and Technology, University of Karachi, Karachi, Pakistan

<sup>2</sup>Laboratoris, Pakistan council of scientific and industrial research, Karachi, Pakistan

<sup>3</sup>pharmacology, Pakistan council of scientific and industrial research, Karachi, Pakistan

### **Background**

*Ph.d Research idea was to explore plant extracts effects*

### **Objectives**

The aim of the present study was to investigate the effect of Botanical Extracts and Essential oils on performance of laying hens

### **Methods**

One hundred and twelve, 40 weeks old, white Novagin laying hens were randomly assigned to seven groups equally (n = 16). Each treatment (group) was replicated four times of four birds per replicate. Experimental diets were prepared by adding A: positive control, antibiotic lincomycin 4.4%, 120mg/kg of feed, antioxidant seldox (BHA, BHT, ethoxyquine and citric acid) 120mg/kg of feed, acetic acid 99.5% pure 0.15ml/kg of feed), B: negative control (N.C) , no antibiotic, antioxidant and acetic acid, C: N.C + black tea poly phenolic extract 1ml/kg of feed, D: N.C + black cumin seed poly phenolic extract 1ml/kg of feed, E: N.C + fenugreek seed poly phenolic extract 1ml/kg of feed, F: N.C + black cumin seed oil 1ml/kg of feed, and G: N.C + fenugreek seed oil 1ml/kg of feed.

### **Conclusions**

Weekly egg production percentage of positive control is significantly higher than negative control ( $P < 0.05$ ) but plant extracts and oils has no significant difference between each other ( $P > 0.05$ ). On the other hand Total bacterial count significantly reduced with increasing age in all treatments except negative control but there is no significant difference between treatments when compared for presence of salmonella and E. coli ( $P > 0.05$ ) in feces.

<sup>2</sup>*ProBioGem laboratory, Charles Viollette ProBioGEM team Université Lille 1, Villeneuve d'Ascq, France*

<sup>3</sup>*ProBioGem laboratory, Charles Viollette ProBioGEM team Université Lille 1, Villeneuve d'Ascq, France*

**Background**

Rhizosphere is the region that is closed to the roots of plant. Plant root exudates consist of a complex mixture of organic acids, sugars and amino acids, which are used as substrates for the growth of bacteria colonizing this rhizosphere.

**Objectives**

we highlighted on the effect of root exudates and some of carbon sources which found in the root exudates, on the bacterial growth and lipopeptides production

**Methods**

Ten of carbon sources (glucose, fructose, sucrose, maltose, xylose, glutamic acid, citric acid, succinic acid, oxalic acid, fumaric acid), and root exudates were used to study bacterial growth and lipopeptides production

**Conclusions**

Different growth kinetics were observed depending of the substrates. For both strains, growth on oxalic acid is very slow and glucose is the best substrate. As a conclusion, the different behavior of the two strains to consume the root exudates and the different carbon sources, which reflex to the growth and lipopeptides production, may be causing the different ability to colonize the rhizosphere.

## **ABUNDANCE AND DIVERSITY OF FUNGAL ENDOPHYTES FROM THE GOTJAWAL FORESTS ON JEJU ISLAND IN KOREA**

W.Y. Bang<sup>1</sup>, H.J. Lee<sup>1</sup>, J.H. Yeo<sup>1</sup>, S.N. Kim<sup>1</sup>

<sup>1</sup>*Biological and Genetic Resources Assessment Division,  
National Institute of Biological Resources, Incheon, Korea*

### **Background**

Endophytes are microorganisms that inhabit plant tissues by colonizing internal plant tissues without causing apparent harm to host. Particularly, some fungal endophytes have beneficial roles on plant growth and plant tolerances to environmental stresses such as abiotic and biotic stresses. Accordingly, identifying their abundance and diversity from unique forest ecosystem is an interested subject to discovery the beneficial fungal endophytes.

### **Objectives**

The objective of this study is to construct endophytic fungal resources for discovering their beneficial functions, by collecting diverse fungal endophytes from the Gotjawal forest (Jeju, Korea), a unique forest ecosystem, and identifying their abundance and diversity.

### **Methods**

Various plant tissues were collected from Gotjawal area on Jeju Island in Korea. They were sterilized and then, subjected to the endophytic fungal isolation. Subsequently, they were further pure-cultured and then subjected to the long-term storage in liquid nitrogen and the DNA isolation for the molecular identification, mediated by various DNA barcode markers.

### **Conclusions**

Forty seven plant samples were collected from five Gotjawal forests on Jeju Island and composed of 34 species. Through the molecular identification, 196 fungal isolates were obtained from the plant tissues and classified as 3 classes, 11 orders, 17 families and 29 genera. Especially, fifty fungal MOTUs (molecular operational taxonomic units) were identified and classified further into four genera such as *Colletitrichum*, *Xylaria*, *Pestalotiopsis*, *Fusarium*. The fungal collection, obtained from Gotjawal forests, was deposited with classification information in National

Institute of Biological Resources as stocks and can become a useful resource to discovery the beneficial functions of fungal endophytes.

**DOES INTERACTION OF THE INVASIVE CORDGRASS SPARTINA DENSIFLORA WITH PLANT GROWTH-PROMOTING RHIZOBACTERIA EXPLAIN ITS TOLERANCE TO PHYSICOCHEMICAL PROPERTIES OF MARSHES SOILS?**

J. Mesa<sup>1</sup>, J.M. Barcia-Piedras<sup>2</sup>, I.D. Rodríguez-Llorente<sup>1</sup>, E. Pajuelo<sup>1</sup>, S. Redondo-Gómez<sup>2</sup>, M.A. Caviedes<sup>1</sup>, J.A. Pérez-Romero<sup>2</sup>, R. Parra<sup>2</sup>, E. Mateos-Naranjo<sup>2</sup>

<sup>1</sup>Microbiología y Parasitología, University of Seville, Seville, Spain

<sup>2</sup>Biología Vegetal y Ecología, University of Seville, Seville, Spain

**Background**

Microbiota in the niches of the rhizosphere zones can affect plant growth and responses to environmental stress conditions via mutualistic interactions with host plants.

**Objectives**

A glasshouse experiment was designed to investigate the role of a bacterial consortium (*Pseudomonas composti* SDT3, *Aeromonas aquariorum* SDT 13 and *Bacillus* sp. SDT14) isolated from the rhizosphere of *Spartina densiflora* in its growth and physiological tolerance to the physicochemical properties of marshes soils.

**Methods**

Plants of *S. densiflora* were randomly assigned to two soil types with different physicochemical characteristics with and without inoculum for 50 days. Plant responses were examined using growth analysis, combined with measurements of gas exchange, efficiency of PSII biochemistry, total content of photosynthetic pigments and leaf water content. In addition the accumulation of nutrients in roots and leaves were determined.

**Conclusions**

The inoculation improved growth of *S. densiflora* through a beneficial effect on its photochemical apparatus due to its impact on chlorophyll concentration. This growth enhancement happened under both soil conditions and was mainly reflected in a greater length and diameter of roots. Modifications of pigment concentrations were linked to an increase in leaf magnesium content. Also, inoculation favoured LWC through the decline in gs and increment in root-to-shoot ratio. Moreover, this consortium was able to stimulate ions uptake in roots and leaves. Plant growth-promoting rhizobacteria of *S. densiflora* appears to play a significant role in its growth response and tolerance to the physicochemical properties of soils, through diverse protective effects on the photosynthetic apparatus, WUE and mineral nutrient balance.

**BACTERIAL CONSORTIA FORMULATED WITH ENDOPHYTIC AND RHIZOSPHERIC BACTERIAL STRAINS, ISOLATED FROM AVOCADO PLANTS, INCREASE SALT STRESS TOLERANCE OF WHEAT SEEDLINGS.**

*P. Barra<sup>1</sup>, N. Inostroza<sup>1</sup>, M.L. Mora<sup>1</sup>, D. Crowley<sup>2</sup>, M. Jorquera<sup>1</sup>*

<sup>1</sup>*Chemical Sciences and Natural Resources, Universidad de La Frontera, Temuco, Chile*

<sup>2</sup>*Environmental Sciences, University of California Riverside, Riverside, USA*

**Background**

The plants growing under salinity stress conditions increase ethylene production, which induces root elongation inhibition. The bacterial enzyme 1-aminocyclopropane-1-carboxylate deaminase (ACCD) cleave ethylene precursor, the 1-aminocyclopropane-1-carboxylate, thus mitigating ethylene effects. Some strains also produce phytohormone indol acetic acid (IAA), which increases cell elongation.

**Objectives**

To determine the effects of inoculation with consortia formulated with IAA- and ACCD-producing endophytic (EB) and rhizospheric bacteria (RB) on salinity stress mitigation of wheat plants.

To compare the effects of EB and RB inoculation, as well as, different levels of bacterial IAA and ACCD production on salinity stress mitigation of wheat plants.

**Methods**

Twelve bacterial strains were isolated from avocado plants, and four consortia were formulated: 1) EB with higher ACCD and IAA production; 2) EB with lower ACCD and IAA production and 3) RB with higher ACCD and IAA production; 4) RB with lower ACCD and IAA production. Wheat seeds were inoculated with the bacterial consortia, and then seeds were grown under salt stress conditions. Length, dry weight and superoxide dismutase (SOD) activity of wheat shoot and roots were determined.

**Conclusions**

At lower levels of bacterial IAA and ACCD production, the EB were more efficient than RB consortia mitigating salt stress effects. Between RB consortia, only those with higher production are able to promote the growth of stressed plants. Both EB and RB consortia with higher production are able to increase SOD activity. Finally,

bacterial strains isolated from avocado plants mitigate plant stress and therefore have the potential to be used as commercial inoculum of avocado plants.

## **CALLOSE DEPOSITION AND ACCUMULATION OF STARCH IN CITRUS AND PONCIRUS LEAVES INFECTED WITH “CANDIDATUS LIBERIBACTER ASIATICUS”**

L.P. Boava<sup>1</sup>, M. Cristofani\_Yali<sup>1</sup>, M.A. Machado<sup>1</sup>

<sup>1</sup>Centro de Citricultura 'Sylvio Moreira', Instituto Agronomico de Campinas, Cordeirópolis, Brazil

### **Background**

Huanglongbing (HLB) is a destructive disease of citrus caused by phloem-limited bacteria, *Candidatus Liberibacter* spp. Although no known HLB-resistant citrus species or varieties have been identified, several studies report the group of *Poncirus trifoliata* and some of its hybrids, as more tolerant to the disease. One of the early manifestations of HLB is excessive starch accumulation in leaf chloroplasts.

### **Objectives**

We hypothesize that callose deposition in the phloem may intervene photoassimilate exportation, causing the starch to over-accumulate. Thus, we examined citrus leaf phloem by microscopy to characterize plant responses to infection.

### **Methods**

We have studied 3 genotypes (*C. sinensis*, *C. sunki* and *P. trifoliata*) and 7 hybrids obtained from crosses between *C. sunki* and *P. trifoliata*. All genotypes (3 replicates) were graft inoculated with budwood from HLB-infected plants and infection was confirmed by qPCR (TaqMan®) 8 months after plants inoculation.

### **Conclusions**

We observed callose deposition in leaf petioles and accumulation of starch in leaves in all genotypes and hybrids, when compared with mock-inoculated controls. However, accumulation of starch and callose deposition were more abundant in *C. sinensis*, *C. sunki* and three of the hybrids. *P. trifoliata* and four of the hybrids showed the lowest starch accumulation and lower deposition of callose, when compared with others genotypes. Our results indicate that *Liberibacter* infection is accompanied by callose deposition in different level among the genotypes and the deposition of callose is higher in susceptible genotypes suggesting that the phloem plugging by callose inhibits phloem transport, contributing to the development of HLB symptoms.

**PYROSEQUENCING ANALYSIS OF SOIL FUNGAL COMMUNITIES OF  
DIFFERENT TRANSFORMATION SYSTEMS IN THE JAMBI PROVINCE  
(SUMATRA, INDONESIA)**

*N. Brinkmann<sup>1</sup>, S.W. Budi<sup>2</sup>, J. Sahner<sup>1</sup>, E. Nur<sup>1</sup>, T. Klein<sup>1</sup>, A. Polle<sup>1</sup>*

*<sup>1</sup>Department of Forest Botany and Tree Physiology, Buesgen-Institute, Göttingen, Germany*

*<sup>2</sup>Silviculture, Bogor Agricultural University, Bogor, Indonesia*

**Background**

In many tropical areas rainforests are cleared in order to transform them into rubber and oil palm plantations, although massive transformations are a major threat for biodiversity. Most of the tree species in rainforests are associated with fungi that form mutualistic interactions with roots and function as key link for nutrient exchange between the above- and belowground compartment. Therefore, in addition to the loss in tree species, transformation of primary forests into intensely managed plantations may lead as well to changes in the fungal community structure of soils or even to a loss of species.

**Objectives**

The goal of this study is to identify potential differences in fungal community structures in soils of tropical lowland rainforests and plantations sites. Furthermore soil-borne plant stress will be evaluated by analyzing arbuscular mycorrhizal (AM) spore density and morphology.

**Methods**

The study is implemented in one of the largest regions of tropical lowland rainforest in Southeast Asia, the Jambi Province (Sumatra, Indonesia). Two landscapes, National Park Bukit Duabelas and Harapan Rainforest, were investigated. Soils of different transformation systems (lowland rainforest, jungle rubber (extensive), intensive rubber and oil palm plantations) were investigated using the 454 Pyrosequencing approach. Fungal soil communities were characterized using internal transcribed spacer regions ITS1 and ITS2.

**Conclusions**

A strong increase of AM spore density in plantations compared to rainforest sites was detected supporting that monoculture tree crops may suffer from soil-born stress.

Currently we are investigating if transformation of tree species rich tropical rainforests to species poor plantations correlates with a loss of fungal diversity in soil.

## **ROLE AND ACTIVITY OF MIRNAS IN THE INTERACTION OF TOMATO ROOTS WITH ENDOPHYTIC POCHONIA CHLAMYDOSPORIA**

I. Pentimone<sup>1</sup>, L. Rosso<sup>1</sup>, F. Nigro<sup>2</sup>, M. Colagiero<sup>1</sup>, A. Ciancio<sup>1</sup>

<sup>1</sup>CNR, Istituto per la Protezione Sostenibile delle Piante, Bari, Italy

<sup>2</sup>Dipartimento di Scienze del Suolo della Pianta e degli Alimenti, Università degli Studi "Aldo Moro", Bari, Italy

### **Background**

MicroRNAs (miRNAs) are endogenous small-RNAs transcribed from non-coding DNA, matching a target messenger RNA to repress translation or induce cleavage. They act in almost every biological plant activity, e.g. development, abiotic stress tolerance, signal transduction, and in defense from pathogens or parasites.

### **Objectives**

To elucidate miRNAs role in plant-endophyte interactions, we constructed libraries from roots of *Solanum lycopersicum* endophytically colonized (Pmi) or not (Pm) by the hyphomycete *Pochonia chlamydosporia*. This fungus shows endophytic behaviour with growth promotion or nematode biocontrol effects. No data are available on tomato miRNAs role and targets in the endophytic interaction.

### **Methods**

Illumina™ NGS of small-RNAs yielded  $9 \cdot 10^6$  (Pmi) and  $12 \cdot 10^6$  (Pm) reads per library. CLC Genomics Workbench was used for trimming, counting, annotation and data analysis.

### **Conclusions**

Non-redundant, unique small-RNAs (869178 in Pmi, 958026 in Pm), were produced. MiRNAs expression was affected by endophytism. Analyses of tomato miRNAs (miRBase, rel.21), revealed miR156 and miR168 (conserved across higher plants), as most abundant in roots. Four further miRNAs (miR169a, miR169c, miR9473 and miR9476), out of 75 known in tomato, were expressed only in Pmi, with seven further (miR169d, miR1917, miR169e, miR394, miR167a, miR5300 and miR9475) over-expressed and 27 down-regulated (fold change range: 1.2–4.8). 37 remaining miRNAs were equally expressed in both conditions. A Pmi comparative analysis showed that 1732 out of 5055 Pmi down-regulated genes were miRNA targets,

involved in structural protein, metabolism, transcription factor, growth and development, stress-related, signaling pathways, storage and other processes.

**CHARACTERIZATION OF THREE ENSIFER MELILOTI BACTERIOPHAGES FROM SOILS SUBJECTED TO ABIOTIC STRESS.**

M.T. Cubo<sup>1</sup>, C. Alías-Villegas<sup>1</sup>, R.A. Bellogín<sup>1</sup>, M. Camacho<sup>2</sup>, F. Temprano<sup>2</sup>,  
M.R. Espuny<sup>1</sup>

<sup>1</sup>MICROBIOLOGY, UNIVERSITY OF SEVILLE, Seville, Spain

<sup>2</sup>Junta de Andalucía, IFAPA CENTRO LAS TORRES-TOMEJIL,  
Alcalá del Río Seville, Spain

**Background**

The presence of bacteriophages in soils was demonstrated as early as 1935. The presence of rhizobiophages in soils suggests that through selection or elimination of certain types of rhizobia, the rhizobiophages influence the evolution of bacterial populations.

**Objectives**

In this work, we isolated 3 *Ensifer meliloti* bacteriophages (EMph1, EMph2 and EMph3) from the rhizosphere soil of *Medicago marina* collected in two areas of the South of Spain. This study is part of a project in which the diversity of rhizobia strains that nodulate *M. marina* was studied in the Odiel river marshes (Huelva) and in the dunes of San Fernando beach (Cádiz), soils subjected to pH and salt stress.

**Methods**

Bacteriophages were isolated from rhizosphere soil samples by the enrichment technique of Barnett (1972). Phages were purified by three successive isolation of single plaques. The basic DNA manipulations and molecular techniques used have been described elsewhere. To study their host range, phages were assayed on 22 different bacteria, 13 of them were strains isolated from *M. marina* nodules, along with additional bacteria, including strains of *E. meliloti*, *E. medicae*, *E. fredii*, *R. tropici*, *R. etli*, *R. leguminosarum* bv. *viciae*, *R.l.* bv. *trifolii* and *Agrobacterium tumefaciens*.

**Conclusions**

The 3 phages were resistant to restriction with many enzymes tested. EMph1 and EMph3 displayed a wide host range within the whole bacteria tested. On the contrary, phage EMph2 exhibited a narrow host range which was capable of killing only 5 out of 22 bacteria tested.

<sup>3</sup>The Laboratory of Plant Cells Growth Mechanisms,

Kazan Institute of Biochemistry and Biophysics RAS, Kazan, Russia

**Background**

Many phytopathogenic bacteria colonize heterogeneous interior of their host consisting of various tissues that form diverse microniches for microorganisms. However, the dynamics of bacterial population structure in such heterogeneous and changing system as plant organism is poorly understood.

**Objectives**

In our investigations we described the dissociation of *Pectobacterium atrosepticum* SCRI1043 (*Pba*) populations and the formation of various subpopulations in tobacco plants.

**Methods**

Microbiological methods; RT PCR; light, transmission electron microscopy; immunocytochemistry; chromatography.

The proliferative potential and bacteria distribution within different plant tissues were analyzed from inoculation time till long-term preservation of microorganisms in dead plant debris. We have revealed new structures totally occluding xylem vessels of the host plant and termed them "bacterial emboli". These structures are composed of tightly packed bacterial cells having a predominant spatial orientation and a peculiar way of formation. Using immunocytochemistry and biochemical methods it was shown that high molecular weight products of pectic compounds degradation and *Pba* exopolysaccharides play an important role in the bacterial emboli formation. Such structures were formed in the plant vessels both in the pronounced and inapparent disease symptoms after *Pba* infection. Bacterial emboli are likely to form conditions for bacterial downward migration through the xylem vessels resulting in rhizosphere colonization. After plant death bacteria were transformed to viable but non-culturable state.

**Conclusions**

Our investigation demonstrates that pectobacteria realize different strategies in colonization of various plant compartments and are able to pass through the life cycle symptomatically and asymptotically.

## **COMPOSING PLANT-MICROBIAL ASSOCIATION RESISTANT TO SOIL SALINIZATION**

A.A. Fedorenchik<sup>1</sup>, N.I. Naumovich<sup>1</sup>, Z.M. Aleschenkova<sup>1</sup>

<sup>1</sup>Laboratory of Interaction between Soil Microorganism and Higher Plants,  
Institute of Microbiology Belarus National Academy of Sciences, Minsk, Belarus

### **Background**

Potash mining by Belaruskali concern poses a grave environmental threat in terms of soil pollution with sodium, potassium and calcium chlorides. Salt-induced stress affects growth and productivity of cultivars. A promising method for salinized soil remediation is field introduction of legume crops, like alfalfa (*Medicago sativa*) upgrading soil fertility due to atmospheric nitrogen fixation of selected rhizobial strains and PGRP bacteria. This work was aimed at isolation of beneficial microorganisms enhancing alfalfa resistance to elevated salt concentrations in soil.

### **Objectives**

Halophilic phosphate-solubilizing and nodulating bacteria.

### **Methods**

Recovery and selection of phosphate-solubilizing bacteria was conducted on TY medium containing chlorides of sodium, potassium, calcium in concentration range 3-15 %. Taxonomic affiliation of isolates was based on physiological-biochemical characterization using VITEK2 identification system.

### **Conclusions**

Four halophilic bacterial cultures able to grow on TY medium comprising 15% NaCl were isolated from specimens of solid saliferous wastes sampled at Starobin potash deposit. The examined isolates were capable to solubilize phosphates and exert favorable influence on seed germination, growth and development of alfalfa. Treatment of alfalfa seeds by strain FM-3 under saline conditions increased germination rate by 50% as compared to control. Nitrogen-fixing strain *Ensifer meliloti* Mst 3-2 isolated from alfalfa nodules displayed good growth on TY medium containing 2% NaCl. Investigation allowed to refer three phosphate-solubilizing isolates to genus *Bacillus*. The isolated strains of nitrogen-fixing and phosphate-solubilizing bacteria are especially attractive as components of plant-microbial association resistant to soil salinization.

## CULTIVATING BIOFUEL CROPS ON MARGINAL LAND: PLANT-ASSOCIATED BACTERIA OF LIGNIN-REDUCED (GMO) ARABIDOPSIS THALIANA AND THEIR CAPACITY TO FACILITATE GROWTH.

M. Gielen<sup>1</sup>, N. Weyens<sup>1</sup>, W. Boerjan<sup>2</sup>, B. Beckers<sup>1</sup>, A. Cuypers<sup>1</sup>, J. Vangronsveld<sup>1</sup>

<sup>1</sup>Centrum voor milieukunde (CMK), Hasselt University, Diepenbeek, Belgium

<sup>2</sup>Department of Plant Systems Biology VIB,

Department of Plant Biotechnology and Bioinformatics Ghent University, Ghent, Belgium

### Background

Producing second generation biofuels out of lignocellulosic biomass can contribute to reduce the food-fuel competition on fertile agricultural soils. However, the **recalcitrance of lignin polymers** is a limitation during processing the biomass to pure cellulose fibers. The efficiency of this process can be increased by using **genetically modified crops** with lower lignin-contents. Though, the genetic modification can have effects on the phenolic compounds inside the xylem which can influence the endophytic bacterial population.

To even further reduce the food-fuel competition, biomass can be cultivated on **marginal land** (containing e.g. cadmium (Cd)). An additional advantage can be the **reduction of contaminants** in these soils by making use of phytoremediation, a process that can be optimised by inoculating bacteria with plant growth promoting capacity (e.g. siderophores, IAA, organic acid and ACC deaminase production).

### Objectives

We want to identify the effects of the genetic modification and/or Cd-exposure on the endophytic bacterial population and determine the endophytic growth promoting capacity.

### Methods

The endophytes of different tissues of *Arabidopsis thaliana* wildtype and reduced lignin mutants, grown in a hydroponic system with and without 3µM CdSO<sub>4</sub>, were isolated and characterised using 16S rDNA amplification/sequencing. Their *in vitro* plant growth promoting capacity was tested using colorimetric tests.

### Conclusions

Differences in bacterial populations due to the genetic modification and Cd-exposure were observed in stems and seeds but they seemed to be less pronounced in leaves. The root endophytic populations were more or less identical. However, among all tissues differences in growth promoting capacity were found.

<sup>2</sup>The Laboratory of Molecular Biology,  
Kazan Institute of Biochemistry and Biophysics RAS, Kazan, Russia

### **Background**

Plants lack an immune system in the sense that it exists in animals. However, they are able to recognize potential pathogens. Lipoxygenase signaling pathway plays an important role in regulation of plant growth and development, cell signaling and defense. Lipoxygenase initiates synthesis of group of bioactive compounds collectively called oxylipins (fatty acid hydroperoxides, hydroxy-, oxo-, or keto-fatty acids, divinyl ethers, volatile aldehydes, or jasmonates). Usually oxylipins are not preliminary formed but synthesized de novo in response to mechanical damage, infection and other stress factors. The main role in the biosynthesis of plant oxylipins belongs to the CYP74 enzymes that are non-classical cytochromes P450: allene oxide synthases (AOS), hydroperoxide lyases (HPL), divinyl ether synthases (DES). A number of AOSs and HPLs have been cloned and characterized from various plant species. DESs are less studied. However, divinyl ethers were found in a large number of organisms.

### **Objectives**

We studied interaction between *Linum usitatissimum*, *Ranunculus acris* and *Selaginella moellendorffii* plants with pathogen bacteria *Pectobacterium atrosepticum* SCRI1043.

### **Methods**

Methods of microbiology, molecular biology, biochemistry, mass spectrometry, NMR and UV spectroscopy.

### **Conclusions**

We cloned and characterized DESs from *L.usitatissimum* (LuDES), *R.acris* (RaDES) and *S.moellendorffii* (SmDES1 and SmDES2). LuDES, RaDES and SmDES2 convert

substrates into divinyl ethers (omega5Z)-etherolenic and (omega5Z)-etheroleic acids, respectively. The main reaction product of SmDES1 is (11Z)-etherolenic acid. (Omega5Z)-etherolenic acid possesses bactericide properties, whereas other divinyl ethers – bacteriostatic properties. Expression of DESs genes after infection is 50 times higher than in control. Thus, DES branch of lipoxygenase cascade involved in plant defense against pathogens.

<sup>2</sup>Graduate School of Life and Environmental Sciences, Osaka Prefecture University, Sakai, Japan

<sup>3</sup>Graduate School of Agricultural Science, Kobe University, Kobe, Japan

<sup>4</sup>RIMG, Kochi University, Nankoku, Japan

### **Background**

Cells of a bacterial pathogen *Ralstonia solanacearum* strain OE1-1 (OE1-1) form biofilms on surfaces of tomato cells adjacent to intercellular spaces after invading tomato plants, and cause bacterial wilt. OE1-1 cells in intercellular fluids but not xylem fluids from tomato plants form mushroom-type biofilms. The production of major extracellular polysaccharide, EPS I, positively regulated by a multi-transcription regulator PhcA is involved in the biofilm formation by OE1-1 cells.

### **Objectives**

We analyzed involvement of biofilm formation by OE1-1 cells in its virulence.

### **Methods**

Among PhcA-positively regulated genes, we created *raIA* encoding furanone synthetase-deleted mutant. Biofilm formation of OE1-1 and the mutant incubated in intercellular fluids from tomato plants were observed under the scanning electron microscope. EPS I production and expression of EPS I production-related genes, *xpsR* and *epsB*, were analyzed. Furthermore, virulence of the strains on tomato plants was analyzed.

### **Conclusions**

The mushroom-type biofilm formation of the *raIA*-deleted mutant significantly reduced, compared to those of OE1-1. Furthermore, expression of *xpsR* and *epsB*, and EPS I production of the mutant significantly reduced. Inoculation with the mutant into tomato plants using root dipping resulted in a significant reduction of bacterial growth in intercellular spaces and loss of its virulence. On the contrary, tomato plants inoculated with the mutant through petiole wilted. The transformation with native *raIA* resulted in recovery of not only EPS I production and biofilm formation but also virulence. These results suggest that biofilm formation of which regulation is positively influenced by *raIA* may be involved in OE1-1 virulence.

## **EFFECTS OF RHIZOBACTERIAL ACC DEAMINASE ACTIVITY ON THE GROWTH OF SOYBEAN UNDER SALINE CONDITION**

D. Jabborova<sup>1</sup>, D. Egamberdieva<sup>1</sup>

<sup>1</sup>*Microbiology and Biotechnology, National University of Uzbekistan, Tashkent, Uzbekistan*

### **Background**

1-aminocyclopropane-1-carboxylate (ACC) deaminase is an enzyme that degrades the precursor of plant hormone ethylene. Plant growth-promoting bacteria that ACC-deaminase facilitate plant growth and development under stress conditions by decreasing plant ethylene levels.

### **Objectives**

This study was conducted to analyse the changes in root architecture and root hair length of soybean induced by three rhizobacteria *Pseudomonas putida* TSAU1, *Pseudomonas aureantiaca* TSAU22, *Pseudomonas* sp.. NUU8 strains containing ACC-deaminase.

### **Methods**

ACC-deaminase activity was determined by monitoring the amount of ammonia generated due to hydrolysis of ACC by the rhizobacterial isolates containing ACC-deaminase. Four salinity levels (5.0, 7.5, 10.0 and 12.5 dSm<sup>-1</sup>) were maintained in the gnotobiotic system using NaCl salt.

### **Conclusions**

Results showed that the salinity adversely affected on the root length of soybean decreasing by 79% the highest NaCl concentration (12.0 dSm<sup>-1</sup>). The bacterial strains could utilize ACC as N source indicating the presence of ACC-deaminase that play a role in reducing ethylene levels in plants. The inoculation of seeds with the *P.putida* TSAU1, *P. aureantiaca* TSAU22, *Pseudomonas* sp. NUU8, increased the root and shoot length of soybean at 5.0, 7.5 and 10.0 dSm<sup>-1</sup> up to 58% compared to uninoculated plants exposed to salt stress. In summary, based on the results of our work we recommend utilization of rhizobacteria having capacity to produce ACC-deaminase to alleviate salt stress of soybean grown in the saline soils.

**Plant/microbes interactions**

## **CO-INOCULATION OF BRADYRHIZOBIUM WITH PSEUDOMONAS STRAINS TO IMPROVE GROWTH AND YIELD OF SOYBEAN UNDER SALINE SOIL CONDITION**

D. Jabborova<sup>1</sup>

<sup>1</sup>*Microbiology and Biotechnology, National University of Uzbekistan, Tashkent, Uzbekistan*

### **Background**

Salinity stress is one of the most serious factors limiting the productivity of agriculture, especially the negative effects on yield and nitrogen fixation of Leguminous plants. However, there are several reports on the positive impacts of co-inoculation with *Pseudomonas* and *Rhizobium* spp., but less attention has been paid how co-inoculation of root-colonising and PGPR bacteria will affect *Rhizobium-Legume* interactions under salinity stress.

### **Objectives**

The objectives of this research were to observe if the co-inoculation of soybean with *Bradyrhizobium japonicum* NU1 and *Pseudomonas* sp. NUU8 can enhance salt tolerance, nodulation, plant growth, pod yield and grain yield of soybean under saline soil conditions.

### **Methods**

The effects of bacterial inoculation on growth, nodulation, pod yield and grain yield of soybean plant grown under saline soil conditions were studied in field experiments. Plants were grown in saline soil of Sherobod district, Surkhandarya province, Uzbekistan.

### **Conclusions**

The results showed that co-inoculation of with *B. Japonicum* NU1 and *Pseudomonas* sp. NUU8 gave more benefits in nodulation, plant growth, pod yield and grain yield of soybean compared to plants inoculated with *B. japonicum* NU1 alone. Under field condition, co-inoculation of *B. japonicum* NU1 and *Pseudomonas* sp. NUU8 strains significantly improved shoot dry weight by 38% and root dry weight by 58% of soybean compared with the uninoculated control. The synergistic use of *B. japonicum* NU1 and *Pseudomonas* sp. NUU8 also improved the nodulation, plant growth, pod yield and grain yield under salt-stress. The results suggested that these strains could be used to formulate a biofertilizer for sustainable production of soybean under salt stressed field conditions.

## **INDOLE ACETIC ACID BIOSYNTHESIS AND NITRIC OXIDE METABOLISM CROSSTALK IN AZOSPIRILLUM BRASILENSE SM**

V. Koul<sup>1</sup>, A. Adholeya<sup>1</sup>, M. Kochar<sup>1</sup>

<sup>1</sup>TERI-Deakin NanoBiotechnology Centre, The Energy and Resources Institute,  
New Delhi, India

### **Background**

Plant growth promoting rhizobacteria, *Azospirillum brasilense* SM releases phytohormone-Indole-3-acetic acid (IAA) and other plant growth regulators into the rhizosphere which enhances plant development. A crosstalk between IAA and gasotransmitter, Nitric oxide (NO) is speculated which may further benefit the plants.

### **Objectives**

To identify NO production by strain SM and unravel potential rhizospheric crosstalk between IAA and NO.

### **Methods**

The study involved creating mutant strains which overexpress essential NO metabolism genes, NO Fluorescence assay, IAA quantification by HPLC, determining plant-bacterial association by SEM, and Real time PCR for gene expression.

### **Conclusions**

Production of NO and presence of NO metabolism genes i.e. nitrous oxide reductase (*nosZ*), nitrous oxide reductase regulator (*nosR*) and nitric oxide reductase (*norB*) were identified by fluorescence assay and PCR sequencing. Improved PGP response of their overexpressing mutant strains was mediated by increased NO and IAA levels. Surface colonization of strain SM on sorghum roots was established by electron microscopy and improved plant development was observed with the mutants. Quantitative IAA estimation suggested that *nosR* and *norBC* influences regulation of IAA biosynthesis in *A. brasilense* SM. The NO quencher, inhibitor and donor reduced or blocked IAA biosynthesis in wild type and mutants, emphasizing a common regulatory role of these molecules in IAA biosynthesis. Expression studies by qPCR showed positive influence of Tryptophan and Arginine on NO genes. IAA biosynthesis gene, indole-3-pyruvate decarboxylase (*ipdC*) was influenced by Tryptophan but not significantly by Arginine. These results impress some shared signalling mechanism or potential crosstalk involving IAA and NO in strain SM.

## **IMPORTANCE OF METHANE FOR SPHAGNUM-ASSOCIATED MICROBIAL NITROGEN FIXATION**

M. Kox<sup>1</sup>, S. Aalto<sup>2</sup>, T. Penttilä<sup>3</sup>, M. Tirola<sup>2</sup>, M.S.M. Jetten<sup>1</sup>, K.F. Ettwig<sup>1</sup>

<sup>1</sup>Microbiology, Radboud University, Nijmegen, Netherlands

<sup>2</sup>Biological and Environmental Sciences, University of Jyväskylä, Jyväskylä, Finland

<sup>3</sup>-, Finnish Forest Research Institute, Vantaa, Finland

### **Background**

Pristine *Sphagnum*-dominated bogs are N-limited and depend on N<sub>2</sub> fixation by diazotrophs or atmospheric N-deposition for their N supply. *Sphagnum* mosses harbor a very diverse microbiome including numerous methanotrophs that contribute to the carbon supply of the mosses. It has been hypothesized that methane might also stimulate *Sphagnum*-associated N<sub>2</sub> fixation during early stages of peat development, thereby increasing *Sphagnum* growth and N content, although other studies did not see this effect.

### **Objectives**

The objectives are to elucidate whether methane indeed does stimulate N<sub>2</sub> fixation in *Sphagnum* mosses from ombro-, oligo- and mesotrophic field sites and to test whether this is affected by oxygen level.

### **Methods**

N<sub>2</sub> fixation and CH<sub>4</sub> oxidation activity were studied by incubating mosses with <sup>15</sup>N<sub>2</sub>, <sup>15</sup>N<sub>2</sub> + <sup>13</sup>CH<sub>4</sub> or no additions. Furthermore, different oxygen regimes (aerobic, microaerobic (either N<sub>2</sub>-He atmosphere or submerged) were applied. DNA and RNA are to be extracted and 16S rRNA and nitrogenase (nifH) genes quantified and analyzed by qPCR and high-throughput sequencing of amplicons.

### **Conclusions**

The isotope tracer-studies showed that only in oligotrophic sites the diazotrophic communities associated with *Sphagnum* reacted positively to methane addition and microaerobic conditions. For mosses from ombrotrophic and mesotrophic sites, diazotrophic activity was neither affected by methane addition, nor by reduced oxygen concentration. Combined, these results indicate that methane dependent nitrogen fixation may only be important under certain environmental conditions in *Sphagnum*-dominated peatlands. Conditions proven to be important for

methanotrophy (pH, water level) and diazotrophic community composition are likely to affect diazotrophy as well, and will be subject of future studies.

<sup>3</sup>*HEXT Core Facility Project, University Medical Center Hamburg-Eppendorf, Hamburg, Germany*

<sup>4</sup>*Centre for Plant Biotechnology and Genomics, University of Madrid, Madrid, Spain*

**Background**

Algae live in close association with microorganisms. However, our knowledge on the physiology and metabolism of complex microbial communities associated with algae is very limited.

**Objectives**

A main goal of our research is to understand the underlying molecular mechanism of species divergence and adaptive processes in microalgae and bacterial systems. According to the fundamental questions "Who's there?" and "What are they doing?", bacterial communities associated with plants and their functions should be analyzed in more detail. We have analyzed the bacterial populations of different microalga and we speculate that these bacteria have evolved a common mechanism to communicate and manipulate their hosts.

**Methods**

The diversity and population dynamic of the bacteria were examined using scanning electron microscope, 16S rRNA gene analysis, MS and metagenome analyses. Moreover, the current work is focused on transcriptome analysis.

**Conclusions**

A comprehensive understanding of microalgae and bacteria interactions requires knowledge of the associated gene expression changes in both the microalgae and the bacteria. So, we will analyze the role of common signaling pathways and signals from eukaryotic and prokaryotic sites. The results will help us to understand overall principles of microbial adaptation and signal exchange in more detail.

## **TRANSCRIPTOMIC ANALYSIS IN RHIZOSPHERIC BURKHOLDERIALES INTERACTING WITH ARABIDOPSIS EXUDATES**

P. Leiva<sup>1</sup>, D. Ruiz<sup>1</sup>, B. González<sup>1</sup>

<sup>1</sup>*Laboratorio Bioingeniería Facultad de Ingeniería y Ciencias,  
Universidad Adolfo Ibañez, Santiago, Chile*

### **Background**

Bacteria are able to colonize a wide spectrum of habitats including the rhizosphere of plants. In such association bacteria may utilize plant root exudates components as carbon and energy source, but also other processes may take place, like degradation of toxics, competition with pathogenic bacteria, phytohormones synthesis, nitrogen fixation, quorum sensing control, and several others. Despite the relevance for agronomical applications, the molecular mechanisms underlying microbe-plant root exudates interactions are poorly understood.

### **Objectives**

To improve understanding of plant-microbe interactions through transcriptomica and metabolomics profiling of selected bacteria exposed to plant root exudates when plants have been grown under different nutritional and stress conditions.

### **Methods**

Cell cultures of two different Burkholderiales species able to associate with Arabidopsis (one plant growth promoting rhizobacterium –PGPR- and the other one a non-PGPR) were exposed to plant root exudates obtained from plants grown on control, N-limitation, and saline or chemical stress conditions, and gene expression profiling: Real Time PCR analysis for specific genes, and complete transcriptomic profile analysis by High-Seq Illumina platform, were obtained. Metabolomic profiling of plant root exudates was done by HPLC-MS.

### **Conclusions**

Plant root exudates exhibit different composition profile according to the growth conditions of the plant. This may explain differential gene expression profiles observed with the PGPR and the non-PGPR species.

**ENDOPHYTIC BACTERIA THE INTROVERT ENGINEERS OF RHIZOSPHERE: A CASE STUDY EMPLOYING THEIR USE FOR REJUVENATION OF APPLE TREES IN SIX DECADE OLD APPLE ORCHARDS**

R. Mahajan<sup>1</sup>, S. Chandel<sup>1</sup>, A. Chauhan<sup>2</sup>, C.K. Shirkot<sup>2</sup>

<sup>1</sup>*Biotechnology and Bioinformatics,*

*JAYPEE UNIVERSITY OF INFORMATION TECHNOLOGY (Previously at Dr.Y.S.Parmar University of Horticulture and Forestry Microbiology Nauni Solan), Shimla, India*

<sup>2</sup>*Microbiology, Dr. Y.S.Parmar University of Horticulture and Forestry, Nauni Solan, India*

**Background**

Apple cultivation a prominent industry in Himachal Pradesh, India occupies an area of 1,01,485 hectares and production reaching 2,11,295 metric tonnes. Today, the six decade old apple orchards are being replaced by new plantations. However, their survival is a major challenge which results in indiscriminate use of chemical inputs. This poses potential threat to environment/human health and therefore managing plant rhizosphere is critical.

**Objectives**

Work presented in here, highlights novelty of *Bacillus* sp. strain CKA1 (apple roots endophyte) in being used as rhizosphere engineer.

**Methods**

Microbial formulation was evaluated under field conditions for its effect on plant establishment; early growth; yield and rejuvenation of diseased apple trees. Whole genome sequencing of the bacterium helped in deciphering molecular mechanisms underlying the multifunctional plant growth promoting potential. Application of microbial formulation resulted in: increased plant biomass (75.40-80.11%); increased Nitrogen (2.42%), Phosphorus (0.58%) and Potassium (1.33%); increased fruit yields (35 to 45%); rejuvenation of diseased apple trees infected with *Dematophora necatrix* in farmer's field over a three year trial. Comparative genomics paved the way for understanding molecular mechanisms involved in the strains ability to function as multifunctional plant growth promoter.

**Conclusions**

Apple orchard rejuvenation projects are being ambitiously launched by State agencies for restoring six decade old planted apple orchards. Integrated nutrient management systems comprising biological systems especially, managing rhizosphere using endophytes such as strain CKA1 opens up new avenues not only for improving crop yield but also in sustaining soil health.

## **POTENTIAL FIBRINOLYTIC ACTIVITY OF AN ENDOPHYTIC XYLARIA CURTA SPECIES FROM WESTERN GHATS OF INDIA**

V. Meshram<sup>1</sup>, S. Saxena<sup>1</sup>

<sup>1</sup>*Department of Biotechnology, Thapar University, Patiala, India*

### **Background**

Endophytic fungi are prominent producers of putative phytochemicals and their analogues which can be exploited as therapeutic interventions/or pharmaceutical agents.

### **Objectives**

The current investigation deals with isolation, purification and characterization of fibrinolytic enzymes produced by endophytic fungal isolates derived from different medicinal plants of Western Ghats of India.

### **Methods**

In preliminary screening assays, 17% of the endophytic fungal isolates expressed fibrinolytic activity whereas 26% of the isolates exhibited proteolytic activity. Maximum fibrinolytic and proteolytic activity was shown by endophytic fungal isolate #37 CRSTBRT which exhibited a halo formation of 113.04 mm<sup>2</sup> on fibrin clot assay. The fibrinolytic enzyme (VM 22) from fungus was purified to electrophoretic homogeneity with the methods including ammonium sulphate precipitation, anion exchange and gel filtration chromatography. The molecular weight of the purified enzyme was estimated to be 35 KDa by SDS-PAGE, fibrin zymography and gel filtration chromatography. The enzyme was stable between 5.5 – 8.5 pH and below 50°C. The optimal pH for the enzymatic activity was 7.8 at 35°C. The purified enzyme also exhibited an 18 fold increase in the enzyme activity. *In vitro* studies also revealed that the enzyme could effectively catalyses the blood clot lysis. Further the endophytic fungal isolate #37 CRSTBRT was identified as a *Xylaria curta* species based on morphological and molecular taxonomic tools.

### **Conclusions**

The fibrinolytic enzyme VM 22 directly lyse the fibrin clot and not by plasminogen activators indicating that this enzyme could be useful in thrombolytic therapy.

**EFFECT OF GENE SILENCING OF THIOREDOXIN H DURING THE COMPATIBLE INTERACTION OF CAPSICUM ANNUUM EUPHORBIA MOSAIC VIRUS-YUCATAN PENINSULA**

O. Moreno-Valenzuela<sup>1</sup>, M.S. Luna-Rivero<sup>1</sup>, C. Hernandez-Zepeda<sup>1</sup>, Y. Minero-Garcia<sup>1</sup>

<sup>1</sup>Bioquímica y Biología Molecular de Plantas,  
Centro de Investigación Científica de Yucatán, Merida, Mexico

**Background**

There are evidence of the participation of salicylic acid (SA) pathway in the plant/virus interaction. Thioredoxins (Trxs) participate as a regulator in this mechanism, and in plants, the *h*-type play a fundamental role in tolerance of oxidative stress and defense responses against pathogens.

**Objectives**

The objective of this work was to analyze the effect of silenced *CaTRXh1* in plants of *Capsicum annuum* during the compatible interaction with the begomovirus *Euphorbia mosaic virus-Yucatán Peninsula* (EuMV-YP).

**Methods**

CaTrxh1 was silenced in plants of *Capsicum annuum* using a VIGs vector based on the TRV. 15 days post-silencing, plants were infected with the EuMV-YP. A time course experiments was done. Plant samples were collected at different times post-inoculation. Gene expression of thioredoxin h, NPR1, and PR10, and EuMV-YP replication were evaluated on the time course by Real Time PCR.

**Conclusions**

*NPR1* and *PR10* genes increase their expression at 14 and 7 days post inoculation (DPI), respectively. In the silenced and infected plants, the expression of *NPR1* decreases in approximately 41% at 28 DPI, while *PR10* gene maintains the same expression at 7 DPI. At 4 hour post inoculation (HPI) it was observed an increase in the SA content in the plant infected with the EuMV-YP and at 1 HPI in the pTRV2:CaTRX/EuMV-YP, compared with the control plants. Also, the viral DNA accumulation was higher in the plants silenced and infected with the begomovirus. These results suggest the participation of *CaTRXh1* on plants of pepper in the mechanism of defense during the compatible interaction to EuMV-YP.

## **INVOLVEMENT OF BIOFILM FORMATION OF *RALSTONIA SOLANACEARUM* IN ITS COLONIZATION IN INTERCELLULAR SPACES**

Y. Mori<sup>1</sup>, K. Inoue<sup>2</sup>, K. Ikeda<sup>2</sup>, H. Nakayashiki<sup>2</sup>, C. Higashimoto<sup>1</sup>, K. Ohnishi<sup>3</sup>,  
A. Kiba<sup>1</sup>, Y. Hikichi<sup>1</sup>

<sup>1</sup>Laboratory of Plant Pathology & Biotechnology, Kochi University, Nankoku, Japan

<sup>2</sup>Graduate School of Agricultural Science, Kobe University, Kobe, Japan

<sup>3</sup>RIMG, Kochi University, Nankoku, Japan

### **Background**

*Ralstonia solanacearum* is a soilborne bacterial pathogen and is the causal agent of bacterial wilt of more than 200 plant species, limiting the crop production around the world. The colonization of *R. solanacearum* strain OE1-1 (OE1-1) in intercellular spaces after invasion through wounds is required for its virulence.

### **Objectives**

We analyzed colonization mechanism of OE1-1 in intercellular spaces.

### **Methods**

The behavior of GFP-labeled OE1-1 cells in intercellular spaces of tomato plants was observed under the fluorescence microscope. OE1-1 cells in intercellular spaces were then observed under the scanning electron microscope (SEM). OE1-1 cells in intercellular fluids and xylem fluids from tomato plants were observed under the SEM. Furthermore, biofilm formation of the major extracellular polysaccharide, EPS I, productivity-deficient mutants was also analyzed.

### **Conclusions**

The observation under the fluorescence microscope showed aggregation of fluorescence from GFP-labeled OE1-1 cells in intercellular spaces. The SEM observation showed attachment of OE1-1 cells on surfaces of tomato cells adjacent to intercellular spaces and biofilm-like structures by OE1-1 cells surrounded by an extracellular matrix. Interestingly, the SEM observation showed that OE1-1 cells incubated in intercellular fluids from tomato plants formed mushroom-type biofilms. On the contrary, incubation in xylem fluids led to a reduction of biofilm formation by OE1-1 cells. Furthermore, EPS I productivity-deficient mutants incubated in intercellular fluids significantly reduced their biofilm formation. Together, colonization of OE1-1 cells in intercellular spaces of tomato plants may consist of their attachment and biofilm formation on surfaces of tomato cells adjacent to intercellular spaces, in which EPS I productivity is involved.

#### LEAF SPRAYING WITH RHIZOBACTERIA FOR BIOLOGICAL CONTROL OF XANTHOMONAS AXONOPODIS PV. PHASEOLI

A. moura<sup>1</sup>, M. Sangiogo<sup>1</sup>, D.P. Rodriguez<sup>1</sup>, M.R. Cappellari<sup>1</sup>, B.O. Corrêa<sup>1</sup>

<sup>1</sup>Fitossanidade, Universidade Federal de Pelotas, Pelotas, Brazil

#### Background

The bean common blight (BCB) is the most important bacterial disease in the tropics. The chemical control of the BCB is neither efficient nor economic. Therefore, is important to develop new approaches to control CBB. Previous studies using seed microbiolization showed that DFs strains and combinations were effective in control leaf, root and vascular diseases (CORRÊA et al., 2014) and changed enzymatic activities (SILVA et al., 2009).

#### Objectives

So, here these rhizobacteria were evaluated by spraying them in leaves inoculated with *Xanthomonas axonopodis* pv. *phaseoli*.

#### Methods

The treatments were *Bacillus* (DFs093, DFs348 and DFs769), *Pseudomonas* (DFs513 and DFs831) and their combinations (DFs93+DFs769+DFs831 and DFs348+DFs769+DFs831) or water (test) sprayed 48 or 24 h before, 24 or 48 h after inoculation of the pathogen. The experiment was conducted in a greenhouse, in a design completely randomized, with six repetitions. The BCB severity was assessed after 96 hours each two days using a diagrammatic scale (0 to 6).

#### Conclusions

The test plants were 100% symptomatic after 120 hours and the final severity was between 5.35 and 5.48. Only the spraying 48 h before the pathogen inoculation result in a significant difference between the bacterial treatments. The treatments DFs513, DFs769, and the combination DFs348+DFs769+DFs831 showed a smaller area under disease progress curve (AUDPC) (20.6, 26.8 and 22.8% respectively). This result suggests the occurrence of induced resistance, since it requires previous spraying, as occurs when these treatments were used to treat seeds.

CORRÊA et al., 2014. Biological Control, 72: 71-75.

## **THE RHIZOSPHERE MICROBIOME OF SEAGRASSES AND THEIR ROLE IN SULFUR PROCESSES**

G. Muyzer<sup>1</sup>, C.B. Cúcio<sup>1</sup>, A. Engelen<sup>2</sup>, R. Costa<sup>3</sup>

<sup>1</sup>*Aquatic Microbiology, University of Amsterdam, Amsterdam, Netherlands*

<sup>2</sup>*Marine Ecology and Evolution Research, University of Algarve, Faro, Portugal*

<sup>3</sup>*Microbial Ecology and Evolution, University of Algarve, Faro, Portugal*

### **Background**

Seagrass meadows grow in coastal, biogeochemically active sediments. These productive ecosystems are distributed from tropical to temperate areas and are dominated by seagrasses, a group of marine angiosperms that is often threatened by the presence of hydrogen sulfide, a phytotoxic gas produced by belowground bacterial communities. The seagrass rhizosphere is still poorly described, however the occurrence of die-off events caused by high levels of sulfide stresses the need to understand these plants and bacterial communities present in their rhizosphere – rhizobiome.

### **Objectives**

The aim of this research was to obtain insight into the seagrass rhizobiome and to answer the following questions: a) Is the rhizobiome plant-specific?; b) Does the rhizobiome co-evolve with its host?; and c) Who are the core species of the seagrass rhizobiome?

### **Methods**

Rhizosphere samples of *Zostera marina*, *Z. noltii* and *Cymodocea nodosa*, bulk sediments and seawater were collected from Portugal, and the former two rhizospheres were additionally collected from France. Next Generation Sequencing of 16S rDNA amplicons was performed using MiSeq Illumina platform.

### **Conclusions**

The rhizobiome of seagrasses differs significantly from their surrounding environment. Although they don't vary at a local scale, the rhizobiomes were significantly different between plants from different geographical locations. The core rhizobiome of seagrasses is mainly composed of OTUs involved in the sulfur cycle (sulfate reduction and sulfur oxidation), and known for their ability to fix nitrogen.

Moreover, our results point to a niche differentiation of sulfur bacteria, in which sulfide oxidation is performed by different taxa.

## **EFFECT OF GFP-LABELED PAENIBACILLUS POLYMYXA ON GROWTH OF AGRICULTURAL CROPS**

K. Padda<sup>1</sup>, A. Puri<sup>1</sup>, C.P. Chanway<sup>2</sup>

<sup>1</sup>Soil Science, University of British Columbia, Vancouver, Canada

<sup>2</sup>Forest and Conservation Sciences, University of British Columbia, Vancouver, Canada

### **Background**

*Paenibacillus polymyxa* strain P2b-2R isolated from internal stem tissue of a naturally regenerating pine seedling fixes nitrogen in association with lodgepole pine seedlings and promotes their growth. It has been shown to colonize lodgepole pine seedling tissues endophytically using a green fluorescent protein (GFP)-labelled derivative of P2b-2R.

### **Objectives**

We wanted to see if the GFP labelled derivative of P2b-2R would fix N and promote growth of corn and canola in ways similar to the wild type strain.

### **Methods**

We inoculated corn and canola seeds with wild type P2b-2R or the GFP labelled derivative of P2b-2R and seedlings were grown for 40 days in a N-limited soil mix. Seedlings were harvested 20, 30 and 40 days after inoculation and evaluated for biological nitrogen fixation and growth promotion.

### **Conclusions**

Seedlings inoculated with the GFP labelled P2b-2R strain derived small amounts of N from the atmosphere (upto 17%) but grew significantly larger than seedlings inoculated with wild type P2b-2R. Seedlings growth was promoted by inoculation with GFP labeled P2b-2R with an increase of upto 40% in height and 70% in biomass as compared to wild type P2b-2R. Thus, we concluded that GFP modification of strain P2b-2R resulted in a significant enhancement of its growth promotion efficacy of corn and canola.

<sup>2</sup>Forest and Conservation Sciences, University of British Columbia, Vancouver, Canada

**Background**

Several bacterial strains of *Paenibacillus* that possessed N-fixing ability were isolated from extracts of surface-sterilized lodgepole pine seedling and tree tissues. One strain, *Paenibacillus Polymyxa* P2b-2R, was found to fix high amounts of nitrogen when reintroduced to lodgepole pine and western red cedar (gymnosperms). But can this bacterial strain fix nitrogen if introduced into agricultural crops?

**Objectives**

We wanted to determine if this bacterial strain could fix N and promote plant growth while living inside or in rhizosphere of agricultural crops (Corn and Canola).

**Methods**

We inoculated corn and canola seeds with P2b-2R and grew seedlings for 40-60 days. Corn seedlings were harvested 10, 20 and 30 days after inoculation and canola seedlings were harvested after 20, 40 and 60 days after inoculation. Seedlings were evaluated for biological nitrogen fixation and growth promotion.

**Conclusions**

Seedling growth was promoted significantly by inoculation with P2b-2R with an increase of upto 35% in height and 30% in biomass from control. P2b-2R also fixed more than 20% of atmospheric nitrogen while living both inside the plant and in the rhizosphere. These results suggest that this bacterial strain has a broad range of hosts and is successful in N-fixation and growth promotion in agricultural crops.

## **EVALUATION OF TEMPERATURE, PH AND CARBON SOURCE IN INDOLE ACETIC ACID PRODUCTION BY YEASTS ISOLATED FROM RIZOSPHERE AND PHYLLOPLANE**

M. Rosa-Magri<sup>1</sup>, A. de Almeida Scarcella<sup>1</sup>, R. Bizarria Junior<sup>1</sup>

<sup>1</sup>*Ciências da Natureza Matemática e Educação, Universidade Federal de São Carlos, ARARAS, Brazil*

### **Background**

It is possible to find naturally in rhizosphere and phylloplane some yeasts species capable of producing phytohormones, solubilize phosphates and other minerals, as well as acting as biological control agent. Despite that, scarce information is known about this microorganism group as plant growth promoters.

### **Objectives**

Considering these, the aim of this study was evaluate the production of phytohormone auxin (indole acetic acid (IAA)) by yeasts, with variations of culture conditions.

### **Methods**

The yeasts evaluated were *Rhodotorula mucilaginosa* (2F32) and *Trichosporon asahii* (3S44), isolated from phylloplane and rhizosphere of sugar cane, respectively, in Brazil, São Paulo State. Yeasts were cultivated in Potato Broth medium, with 20 g/L of glucose or sucrose, as carbon source; the cultivation of yeasts was carried out at temperatures 22°C, 25°C or 30°C; pH was modified to 3.0, 4.5 or 6.0. All cultures were analyzed by colorimetric technique with reaction of broth and Salkowsky reagent; the cells count was realized to evaluate the development of yeasts.

### **Conclusions**

The results for *T. asahii* showed that IAA production with sucrose was superior at pH 6.0, and glucose was superior at pH 4.5; these results indicate direct relation between carbon source and pH medium. *Rh. mucilaginosa* presented a high IAA production if compared with *T. asahii* or even with microorganisms related in literature; the higher production (655 µg/ml) was obtained at pH 6.0 and glucose as carbon source. Temperature was not able to influence IAA production, significantly. Variations of culture conditions did not affect the cell growth of yeasts.

## **ANALYSIS OF METABOLIC CHANGES IN MESORHIZOBIUM LOTI DURING NODULE MATURATION BY QUANTITATIVE PROTEOMICS**

Y. Tatsukami<sup>1</sup>, M. Nambu<sup>1</sup>, H. Morisaka<sup>1</sup>, K. Kuroda<sup>1</sup>, M. Ueda<sup>1</sup>

<sup>1</sup>Div. Appl. Life Sci., Grad. Sch. Agric. Kyoto Univ., Kyoto, Japan

### **Background**

Rhizobia are nitrogen-fixing bacteria that establish a symbiotic relationship with leguminous plants. After entering the root cells, rhizobia differentiate into bacteroids within the root nodule of the host plant, and provide the plant with fixed nitrogen. Inside nodule, it has been believed that bacteroids construct optimal environment for nitrogen fixation, but the details are still unknown. We have previously evaluated the intercellular proteome of rhizobia<sup>1</sup>.

### **Objectives**

To understand the mechanism by which rhizobia alter their metabolism to establish nitrogen-fixing symbiotic relationship with hosts, time-course quantitative proteome analysis of *Mesorhizobium loti*, one of the model rhizobia, was performed during the nodule maturation.

### **Methods**

*Lotus japonicus* was inoculated with *M. loti*. Nodules were harvested at 2, 3, and 4 weeks post-inoculation. Bacteroids were extracted from nodules, and their proteins were extracted, digested by trypsin, and labeled by Tandem Mass Tag. The prepared samples were analyzed by LC-MS/MS equipped with a 500 cm-long monolithic silica capillary column<sup>2</sup>.

### **Conclusions**

Using a quantitative proteomics approach, we identified and quantified 537 proteins in *M. loti* bacteroids. The results revealed significant changes in the carbon and amino acid metabolisms upon differentiating into bacteroids. Furthermore, our findings suggest that *M. loti* enters a nitrogen-deficient condition during the early stages of nodule development, and changes to a nitrogen-rich condition in the intermediate stages<sup>3</sup>.

**FUNCTIONAL GENOMICS ANALYSIS OF SALMONELLA-TOMATO INTERACTIONS REVEALS MICROBIAL ADAPTATIONS AND PLANT RESPONSES TO THE INFECTION BY A HUMAN PATHOGEN**

M. Teplitski<sup>1</sup>, M. Marvasi<sup>1</sup>, M. de Moraes<sup>1</sup>, J. Giovannoni<sup>2</sup>, M. McClelland<sup>3</sup>

<sup>1</sup>Soil and Water Science, University of Florida/IFAS, Gainesville, USA

<sup>2</sup>Plant Biology, USDA-ARS, Ithaca, USA

<sup>3</sup>School of Medicine, University of California-Irvine, Irvine, USA

**Background**

As the number and severity of produce-associated gastroenteritis outbreaks increase, we are coming to recognize that we know little about the ecology of *Salmonella* and enterovirulent *E. coli* outside of their animal hosts.

**Objectives**

The objective of this work was to delineate mechanisms behind interactions of a model human pathogen, *Salmonella enterica*, and its alternate plant host.

**Methods**

TnSeq and RNAseq analyses of *Salmonella* behavior in tomatoes and tomato responses to the colonization by the pathogen were used to reveal key mechanisms of bacterial adaptation to persistence within tomato and plant responses to the colonization by the human pathogen. Expression of individual genes was confirmed by qPCR and Recombinase-based *in vivo* Technology (RIVET).

**Conclusions**

*Salmonella* virulence genes located on the Pathogenicity Islands were not involved in persistence within tomato fruit. We identified important functions for the regulators of capsule synthesis (*yihT*, *rcsB*) in the phenotype. *Salmonella* genes involved in *de novo* synthesis of amino acids were critical to persistence within tomato fruits. *Salmonella* gene expression depended on the host maturity and genotype, for example, RIVET assays confirmed that *cysB* was expressed strongly in a tomato cultivar known to be resistant to a tomato pathogen *Ralstonia solanacearum*, while *fadH* was responsive to the maturity-dependent accumulation of specific fatty acids. Proliferation of the pathogen was restricted in the plant mutants defective in ethylene synthesis and response (*rin*, *Nr*, *nor*). Tomato genes involved in responses to plant pathogens were activated in response to *Salmonella* infection, however, typical responses to infection were only observed in ethylene mutants.

## **ENDOPHYTIC COMMUNITIES OF ARABIDOPSIS THALIANA: DOES CULTIVATION SUBSTRATE MATTER?**

S. Truyens<sup>1</sup>, B. Beckers<sup>1</sup>, S. Thijs<sup>1</sup>, N. Weyens<sup>1</sup>, A. Cuypers<sup>1</sup>, J. Vangronsveld<sup>1</sup>

<sup>1</sup>*Environmental Biology, Hasselt University, Diepenbeek, Belgium*

### **Background**

Bacterial endophytes colonize the internal tissues of plants without causing harm. An important subgroup are seed endophytes that are transferred from one generation to the next and that are already present during the early plant growth stages. Several studies suggest that seeds can serve as a vector for beneficial bacteria and that these bacteria could improve plant growth.

### **Objectives**

We want to determine the effect of different cultivation substrates, which are frequently used during bulking of *Arabidopsis thaliana* seeds, on the seed endophytic population of this model plant.

### **Methods**

*Arabidopsis thaliana* was cultivated on sand (bacteria-poor) and on a mixture of sand with potting soil (bacteria-rich). Seeds harvested on both substrates were sown again on the same substrate until the radicle emerged or until there were 3 week-old leaves. Cultivable endophytes were isolated from soil, seeds, radicles and leaves, and identified using 16S rDNA amplification and sequencing. Total bacterial populations were identified by a direct DNA extraction on soil, seeds, radicles and leaves, followed by amplification and 454 pyrosequencing of the V5-V7 hypervariable region of the 16S rDNA.

### **Conclusions**

Despite large differences in the soil bacterial populations, the seed endophytic populations were very similar, which indicates that plants are able to select which bacteria can become seed endophytes. This can impact on the establishment of the endophyte community of the next generation of plants.

**Plant/microbes interactions**

## **COMPARATIVE EFFECT OF BIO AND NPK FERTILIZERS ON THE GROWTH OF LETTUCE (LACTUCA SATIVA L.)**

K.T. Kareem<sup>1</sup>, E.O. Ugoji<sup>2</sup>, O.O. Aboaba<sup>2</sup>

<sup>1</sup>Grain Legumes Improvement Programme,

Institute of Agricultural Research and Training, Ibadan, Nigeria

<sup>2</sup>Department of Microbiology, University of Lagos, Lagos, Nigeria

### **Background**

The use of inorganic fertilizers has been established to cause environmental problems.

### **Objectives**

The study investigates the effect of a biofertilizer, *Trichoderma longibrachiatum* NGJ167 and NPK fertilizer on the growth of two varieties of lettuce (Greatlake and Eden).

### **Methods**

The study was carried out in the screenhouse by inoculating soils with mycelial plugs of *T. longibrachiatum* NGJ167 and compared with NPK-fertilizer. Thereafter, *in-vitro* and conventionally propagated lettuce were planted on the treated soils and plant growth parameters observed.

### **Conclusions**

Results showed that the micro-propagated Greatlake lettuce treated with *T. longibrachiatum* had higher plant height (22.23 cm) while the *in-vitro* propagated Greatlake lettuce treated with NPK-fertilizer had mean plant height value of 14.17 cm. The conventional propagated Greatlake and Eden treated with *T. longibrachiatum* had mean plant heights of 17.23 cm and 15.07 cm respectively while the controls had average values of 2.67 cm and 12.4 cm respectively. The average number of leaves of the *in-vitro* propagated Greatlake and Eden lettuce treated with *T. longibrachiatum* (7 and 4 respectively) were higher than those of the NPK-fertilized Greatlake and Eden lettuce (6 and 5 respectively). The result of the fresh biomass revealed that the conventional propagated Eden lettuce treated with *T. longibrachiatum* had an average value of 19.77 g while the NPK-fertilized plants had a mean of 15 g. The implication of these results showed that *T. longibrachiatum* NGJ167 was better than NPK fertilizer with respect to the growth of lettuce. The study concluded that the use of *T. longibrachiatum* improved the growth of lettuce.

**MOLECULAR CHAPERONES OF THE TYPE III SECRETION SYSTEM ARE NOT REQUIRED FOR SECRETION OF THEIR PARTNER SUBSTRATES, BUT CAN BLOCK EFFECTOR TRANSPORT IN PECTOBACTERIUM CAROTOVORUM**

L. Valentovich<sup>1</sup>, A. Titova<sup>2</sup>, O. Miamina<sup>3</sup>, Y. Nikolaichik<sup>3</sup>

<sup>1</sup>Center of analytical and genetic engineering studies,  
Institute of Microbiology of the National Academy of Sciences of Belarus, Minsk,  
Belarus

<sup>2</sup>Department of Microbiology, Belarusian State University, Minsk, Belarus

<sup>3</sup>Department of Molecular Biology, Belarusian State University, Minsk, Belarus

**Background**

*Pectobacterium carotovorum* (*Pca*) is a plant pathogenic soft rot bacterium that can use the type III secretion system (T3SS) to suppress host defence. T3SS is utilized by many Gram negative bacterial pathogens to inject bacterial virulence proteins into eukaryotic cells, where they can manipulate host cell processes to pathogen advantage. T3SS chaperones are involved in protein transport, but their exact function is still unclear in many cases. In *Pca* two potential T3SS chaperones are coded for by the divergent transcriptional units, *dspEF* and *hrpWshcW*. Chaperone function was suggested for the DspF protein in related bacterium *Erwinia amylovora*, but not in *Pca*, while the ShcW protein was not studied before.

**Objectives**

Determine the role of DspF and ShcW in T3SS-dependent protein transport in *Pca*.

**Methods**

PCR, molecular cloning, directed mutagenesis, DNA sequencing, far-western blotting, two-hybrid screening.

**Conclusions**

We have found no evidence for chaperone requirement for stability or secretion of the DspE and HrpW effector proteins. On the other hand, introduction of additional copies of the *dspF* or *shcW* genes into *Pca* cells blocks their ability to induce hypersensitive response on nonhost plants. This phenotype is caused by a severe defect in translocation of effectors into plant cells. Translocation of the DspE-Cya fusion appeared to be completely blocked while translocation of AvrPto-Cya – reduced from *Pca* cells carrying *dspF* on a plasmid. Thus, additional molecules of T3SS chaperones can block effector translocation, while their native amounts are not required for secretion/translocation. This suggests that the main function of the DspF and ShcW chaperones may be to repress premature effector transport.

**CYCLIC  $\beta$ -(1,2)-GLUCAN FROM XANTHOMONAS CAMPESTRIS PV. CAMPESTRIS SUPPRESSES ARABIDOPSIS THALIANA IMMUNITY BY MODULATING FLAGELLIN INDUCED DEFENSE.**

*L. Toum<sup>1</sup>, V. De Pino<sup>1</sup>, G. Gudesblat<sup>1</sup>, A. Vojnov<sup>1</sup>*

<sup>1</sup>Fundación Pablo Cassará, Instituto de Ciencia y Tecnología "Dr. Cesar Milstein"-CONICET, CABA, Argentina

**Background**

Plants are constantly exposed to microbes, such as bacteria, fungi or viruses and most plants are resistant to most microbes. To be successful, a pathogen must overcome constitutive defenses or suppress induced defenses. Our group previously demonstrated that cyclic  $\beta$ -(1,2)-glucan, a polysaccharide synthesized by *Xanthomonas campestris pv. campestris*, suppresses the accumulation of callose deposition, as well as the local and systemic expression of PR1, a defense-related gene associated with salicylic acid responses (The Plant Cell. 2007: 2077-2089).

**Objectives**

To gain knowledge about the mechanism of cyclic glucan in the modulation of plant defense

**Methods**

We performed *Xanthomonas campestris pv. campestris* infection assays on *A. thaliana* leaves pretreated with flagellin (flg22) and purified cyclic glucan or both. Measurement of WRKY22, WRKY33 and MPK3 expression was done by RT-PCR and binding assays was made using *Arabidopsis* membranes and labeled <sup>14</sup>C-cyclic glucans.

**Conclusions**

We observed that cyclic glucans of *X. campestris* suppresses partially the immunity elicited by flg22 in *Arabidopsis thaliana*. In addition, this compound downregulates WRKY22, WRKY33 and MPK3 expression, early defense genes induced by this elicitor. In order to get further insights into how CG modulates flg22 responses, we performed binding assays with *Arabidopsis* membranes and labeled <sup>14</sup>C-CG. The radiolabeled glucan, <sup>14</sup>C-CG, bound specifically to wild-type plant extracts, suggesting the existence of direct interaction between CG and an still unknown *Arabidopsis* receptor. The present results shed light on the mechanism by which *Xcc* CG hijacks, at least partially, plant immune response.

#### **XBMR, A NOVEL TRANSCRIPTION FACTOR REGULATES CHEMOTAXIS, BIOFILM FORMATION AND VIRULENCE IN XANTHOMONAS CITRI SUBSP. CITRI**

P.M. Yaryura<sup>1</sup>, V.P. Conforte<sup>1</sup>, F. Malamud<sup>1</sup>, R. Roeschlin<sup>2</sup>, V. de Pino<sup>1</sup>, A.P. Castagnaro<sup>3</sup>, Y. McCarthy<sup>4</sup>, M. Dow<sup>4</sup>, M.R. Marano<sup>2</sup>, A. Vojnov<sup>1</sup>

<sup>1</sup>Fundación Pablo Cassará, Instituto de Ciencia y Tecnología "Dr. Cesar Milstein"-CONICET, CABA, Argentina

<sup>2</sup>Facultad de Ciencias Bioquímicas y Farmacéuticas Universidad Nacional de Rosario, Instituto de Biología Molecular y Celular de Rosario(IBR)-CONICET, Rosario, Argentina

<sup>3</sup>Sección Biotecnología, Estación Experimental Agroindustrial Obispo Colombres, Tucumán, Argentina

<sup>4</sup>School of Microbiology, University College Cork, Cork, Ireland

#### **Background**

Citrus canker is one of the most important and aggressive bacterial diseases of citrus trees. The causal agent of this disease is *Xanthomonas citri* subsp. *citri* (Xcc). Biofilm formation on citrus leaves plays an important role in epiphytic survival of Xcc. Previous work from our laboratory described a genetic screen for biofilm formation-defective mutants in Xcc, this work identified that a mutant with a transposon insertion in XAC3733 (*xbmR*) had significantly reduced attachment to a polystyrene surface (Microbiology. 2013: 159, 1911–1919).

#### **Objectives**

To gain knowledge about the regulatory mechanisms of Xcc infection

#### **Methods**

For in vitro analysis of biofilm formation, we used confocal laser scanning microscopy. For pathogenicity assays grapefruits leaves was used as the host plant for Xcc. Gene expression levels was obtained by qRT-PCR. Intracellular alteration in c-di-GMP was achieved by exogenous expression of either the diguanylate cyclase WspR19 from *P. fluorescens* or the c-di-GMP phosphodiesterase PA2567 from *P. aeruginosa*.

#### **Conclusions**

A knock-out of *xbmR* led to a substantial downregulation of *fliA*, which encodes a  $\sigma^{28}$  transcription factor, as well as *fliC* and XAC0350 which are potential member of the  $\sigma^{28}$  regulon. XAC0350 encodes an HD-GYP domain cyclic di-GMP phosphodiesterase. These findings suggest that XbmR is a key regulator of flagellar-

dependent motility and chemotaxis exerting its action through a regulatory pathway that involves FliA and c-di-GMP.

**Pollutant degradation**

## **MICROBIAL RESOURCES TO BIODEGRADE COMPLEX TAR AFTER STEAM GASIFICATION PROCESSES**

S. Ciccazzo<sup>1</sup>, S. Manara<sup>1</sup>, L. Brusetti<sup>1</sup>

<sup>1</sup>*Faculty of Science and Technology, Free University of Bolzano, Bolzano, Italy*

### **Background**

Biomasses gasification produces toxic compounds (tar), mainly composed by polycyclic aromatic hydrocarbons (PAH). Up to now the problem of the tar disposal is not solved. Bioremediation of tar with a mixed microbial consortium could be a highly promising and innovative approach for the handling of this by-product.

### **Objectives**

The aim of this study was to assess the tar-degradation process in a laboratory-scale microcosm.

### **Methods**

Triplicate tar-containing microcosms (PAH 13,904 mg/L) were incubated for 20 days with a microbial consortium selected from pinewood and polluted soils. After 20 days HPLC and GC/MS showed a significant reduction of all the PAH compounds to about 150 mg/L whereas PAH concentration in the negative controls was about 8,400 mg/L. Reliability of distinct replicated microcosms was very high since microbial communities showed 97% of similarity. Automated fingerprintings and ribosomal gene pyrosequencing showed, at first, a noticeable lag-phase (0-2 days), where fungi were the leading part of the community. A second phase was evident between 3 and 10 days of degradation with specific bacterial genera. After 15 days, a stable phase with 24 bacteria genera and only one fungal genus was detected. Overall, a total of 59 bacterial and 22 fungal genera participated in the degradation.

### **Conclusions**

Bacterial species grew according to a “cross-feeding” behavior. Natural and polluted soils proved to successfully provide valuable microbial taxa for innovative services such as tar degradation.

**FEMS-1716**

**Pollutant degradation**

**COMPARISON OF BACTERIOPLANKTON COMMUNITIES AND DIESEL BIOREMEDIATION ABILITY OF NATIVE BACTERIA FROM DIFFERENT MEDITERRANEAN TOURIST PORTS**

*E. Bullita<sup>1</sup>, N. Frigau<sup>1</sup>, C. Ruggeri<sup>1</sup>, S. Sergi<sup>1</sup>, G. Erby<sup>2</sup>, A. Carucci<sup>2</sup>, E. Tamburini<sup>1</sup>*

<sup>1</sup>*Biomedical Sciences, University of Cagliari, Monserrato (CA), Italy*

<sup>2</sup>*Civil-Environmental Engineering and Architecture, University of Cagliari, Cagliari, Italy*

**Background**

Tourist ports are subjected to seasonal impacts determining high pollution by petroleum hydrocarbons. Bioremediation is an emerging clean-up technique based on the addition of amendments or microorganisms able to stimulate the degradation activity of the autochthonous bacteria.

**Objectives**

This study was carried out within MAPMED, a multidisciplinary project aimed to improve the environmental sustainability of tourist ports in the Mediterranean Sea with regard to hydrocarbon pollution. Cagliari (Italy), El Kantaoui (Tunisia), and Heraklion (Greece) were selected as case study sites. The present study aims to compare bacterioplankton, hydrocarbon degraders, and the effects of different bioremediation additives on the autochthonous communities among the selected sites.

**Methods**

The structures of bacterioplankton were compared by 16S rRNA T-RFLP among sites, sections with different usage and seasons (winter, beginning and end of the tourist season). Cultivable hydrocarbon degraders were characterized regarding phylogenetic position and catabolic abilities. Different bioremediation treatments (biostimulation with nutrients and bioaugmentation with selected strains) were tested in seawater microcosms supplemented with diesel. The monitoring parameters are the titles of heterotrophs and diesel degraders, and the hydrocarbon removal efficiency. At the end of treatments, the bacterioplankton communities are compared by 16S rRNA gene analysis.

**Conclusions**

The structure analysis highlights a clear seasonal variation in bacterioplankton and differentiates Heraklion communities from those found in Cagliari and El Kantaoui. Degraders exhibiting different ecological strategies dominate the three communities, copiotrophics in Cagliari and hydrocarbonoclastic bacteria in El Kantaoui and

Heraklion. Comparison of the effects of different bioremediation treatments is currently in progress.

## Pollutant degradation

### EXTRACELLULAR DNA AS BIOSCAFFOLD FOR THE SYNTHESIS OF SUPERIOR PALLADIUM(0) NANOCATALYSTS HIGHLY ACTIVE IN THE DETOXIFICATION OF PERSISTENT ORGANOHALOGEN POLLUTANTS

M. Schlüter<sup>1</sup>, F. Schmidt<sup>1</sup>, L. Böhm<sup>2</sup>, M. Müller<sup>3</sup>, F. Axt<sup>2</sup>, F. Fischer<sup>2</sup>, A. Wisthaler<sup>4</sup>, R.A. Düring<sup>2</sup>, M. Bunge<sup>1</sup>

<sup>1</sup>Institute of Applied Microbiology, University of Giessen, Giessen, Germany

<sup>2</sup>Institute of Soil Science and Soil Conservation, University of Giessen, Giessen, Germany

<sup>3</sup>Institute for Ion Physics and Applied Physics, University of Innsbruck, Innsbruck, Austria

<sup>4</sup>Department of Chemistry, University of Oslo, Oslo, Norway

#### Background

In a search for new aqueous-phase systems for catalyzing reactions of environmental and industrial importance, we prepared novel palladium(0) nanocatalysts in the presence of *Shewanella oneidensis* strains. Especially a nuclease-deficient mutant of *Shewanella oneidensis* MR-1 showed an increased tolerance against elevated heavy-metal stress, obviously as a result of high levels of extracellular DNA (eDNA) and additional adaptive response mechanisms.

#### Objectives

The main objective of our study was to assess whether eDNA is able to protect *S. oneidensis* cells from toxic Pd(II) ions and can simultaneously serve as a scaffold for nanocatalyst synthesis.

#### Methods

With eDNA as nucleation site, it was possible to retrieve superior nanocatalysts, bearing small sizes, a monodisperse size distribution and low aggregation behaviour which are important prerequisites for high catalytic activity. Furthermore, in comparison to catalysts produced by the *Shewanella oneidensis* wildtype, the nanocatalysts synthesized by the mutant were more resistant against catalyst transformation, deactivation and poisoning. The catalytic properties of the palladium(0) nanocatalysts were tested using a newly developed real-time PTR-ToF-MS analytical technique, which is able to follow the nanocatalyst-mediated detoxification of highly-persistent anthropogenic pollutants at environmentally relevant concentrations. The palladium(0) nanocatalysts synthesized in the presence of the nuclease-deficient mutant of *Shewanella oneidensis* MR-1 showed a high catalytic activity for the dehalogenation of hexachlorobenzene and triclosan.

#### Conclusions

Further tests with 'old' and emerging halogenated persistent organic pollutants are under way and will demonstrate the high potential of Pd(0) nanocatalysts for clean-up of drinking water, aquifers and specific industrial effluents, as well as the suitability of PTR-ToF-MS to assess the respective transformation and detoxification reactions.

**Pollutant degradation**

**COMPARATIVE STUDY OF THE CAPACITY OF CARRIERS: ANOXKALDNE K1, POLYPROPYLENE PADS AND GRANULAR CORKSORB TO FORM HYDROCARBON-DEGRADING BIOFILMS AND REMOVE HYDROCARBONS FROM DIESEL POLLUTED WATER**

*A. Rodríguez-Calvo<sup>1</sup>, T. Robledo-Mahon<sup>1</sup>, G.A. Silva-Castro<sup>1</sup>, M. Manzanera<sup>1</sup>, J. González-López<sup>1</sup>, C. Calvo<sup>1</sup>*

*<sup>1</sup>Microbiology Institute of Water Research, Universidad de Granada, Granada, Spain*

**Background**

Hydrocarbons are a widely distributed pollutant that reaches the environment from multiple sources and involve significant risks to the environment that must be minimized

**Objectives**

To design a new treatment system for hydrocarbon contaminated water based on biofilm technology, we studied three different carriers 1) AnoxKaldnes™ (a plastic carrier). 2) Polypropylene pads, these are oil absorbent pads composed of 100% meltblown polypropylene that absorb oil only and not water. 3) Granular thermal treated hydrophobic cork which absorbs oil and solvents without absorbing water.

**Methods**

Using 1L bioreactor with 400 ml of water and 200 ml of carrier, kinetics of growth and adherence to carriers were determined by enumeration of viable cells. Development of biofilm was visualized by scanning electron microscopy. TPH, n-alkanes, branched-alkanes and naphthalene removal were determined by GC/MS at the beginning and at the end of the assays. *Pseudoalteromonas elyakovii* strain W18 was inoculated to study biofilm formation. Waters with and without 1% (v/v) diesel, were used to analyze the characteristics of formed biofilm and the efficiency of hydrocarbon removal by indigenous microorganisms.

**Conclusions**

No inhibitory effect of carriers was observed, even in bioreactors with high hydrocarbon contamination. SEM analyses showed that Polypropylene pads and Granular CorkSorb allow microbial biofilm formation. GC/SM analyses showed that Polypropylene pads not only enhance microbial growth but also retain high amount of hydrocarbons.

<sup>2</sup>*Sub-department of Environmental Technology, Wageningen University, Wageningen, Netherlands*

<sup>3</sup>*Laboratory of Microbiology, Wageningen University, Wageningen, Netherlands*

#### **Background**

Aliphatic hydrocarbons (AHC) are abundant in crude oil and fuels, and are frequent contaminants of water, soil and sediments. There is potential for AHC bioremediation using sulfate as electron acceptor, due to its abundance in marine environments and natural presence in soils and groundwater.

#### **Objectives**

In this work sulfate-reducing anaerobic microorganisms involved in AHC biodegradation were studied.

#### **Methods**

Anaerobic sludge was incubated at 37°C with hexadecane (1mM) and sulfate (20mM) in serum vials. Cultures were successively transferred to fresh medium until a stable enrichment was obtained (monitored by microscopy and PCR-DGGE of 16S rRNA gene). For isolation of AHC-degrading bacteria, serial dilutions and successive transfers are now running using palmitate (1mM) as an easier substrate.

#### **Conclusions**

Cultures growing on palmitate show two main bacterial cell types: a rod-shaped bacterium closely related to *Desulfomonile limimaris* (94% identity) was predominant in the first 30 days of incubation, when 83% of the added palmitate was degraded coupled to 4 mM sulfate reduction (suggesting stoichiometric palmitate conversion to acetate); and an oval-shaped bacterium related to *Desulforhabdus amnigena* (99% identity) that mainly developed when incubations were extended and a total of 11.5 mM sulfate was reduced. Growth of *Desulforhabdus* was stimulated when incubated with acetate. The role of the *Desulfomonile* in AHC degradation will be further discussed in the presentation, as well as its halorespiring ability, a characteristic of

the Desulfomonile genera. Further characterization of this novel bacterium is important due to its high potential for bioremediation of hydrocarbons, fats and halogenated pollutants.

## **APPLICATION OF HIGHLY EFFECTIVE MICROBIAL DEGRADERS OF OILS AND FATS IN WASTEWATERS DECONTAMINATION**

M.S. Chyrykava<sup>1</sup>, T.P. Shakun<sup>1</sup>, E.M. Glushen<sup>1</sup>, G.M. Petrova<sup>1</sup>, A.S. Samsonova<sup>1</sup>

<sup>1</sup>Laboratory of xenobiotic degradation and bioremediation of natural and industrial media, Institute of Microbiology, Minsk, Belarus

### **Background**

Disposal of municipal sewage and industrial effluents remains a top priority challenge. Annual discharge of wastewaters containing lipid substances in Belarus reaches 10-12 mln ton. It is recommended to utilize high-efficient microbial strains decomposing oils and fats for their remediation.

### **Objectives**

Searching and examination of microorganisms-degraders of lipid compounds.

### **Methods**

Isolation of microbial strains was carried out by enrichment culture technique. Lipase activity was evaluated by Ota-Yamada method. Dynamics of lipid dissimilation was monitored on model water comprising fats (lard, dairy) and oils (sunflower and olive) in concentration 1000 mg/l as the sole carbon sources.

### **Conclusions**

Four superactive bacterial strains *Rhodococcus ruber* 2B, *Rhodococcus* sp. R1-3FN, *Bacillus subtilis* 6/2-APF1, *Pseudomonas putida* 10AP – degraders of fatty substrates showing lipase activity levels in the range 0.65-0.70 u/mg protein were derived by adaptive selection method. It was found that the selected strains were capable to consume 83.4-94.2 % of animal fats and 82.3-90.4 % of vegetable oils in 7 days. Nutrient medium composition was defined and optimized in terms of nitrogen, potassium, phosphorus and carbon sources. It allowed to attain maximum biomass concentrations (3.0-4.8 g/l by 48 h of fermentation) with elevated lipase activity.

Based on the obtained data technology of manufacturing microbial preparation to accelerate disposal of lipid pollutants in wastewaters was developed.

Introduction of new microbial product into biodecontamination scheme promoted 15.9 % decline in chemical oxygen demand, increased degree of lipid removal by 59 % and improved quality of activated sludge.

**APPLICATION OF CARBON STABLE ISOTOPE ANALYSIS (CSIA) TO INVESTIGATE BIODEGRADATION AND DIRECT PHOTOLYSIS OF ANTIBIOTIC SULFAMETHOXAZOLE**

*D. Cichocka<sup>1</sup>, J. Birkigt<sup>2</sup>, T. Gilevska<sup>2</sup>, B. Ricken<sup>1</sup>, H.H. Richnow<sup>2</sup>, D. Vione<sup>3</sup>, I. Nijenhuis<sup>2</sup>, P.F.X. Corvini<sup>1</sup>*

<sup>1</sup>*Institute for Ecopreneurship School for Life Sciences, University of Applied Sciences and Arts Northwestern Switzerland - FHNW, MuttENZ, Switzerland*

<sup>2</sup>*Department of Isotope Biogeochemistry, Helmholtz Centre for Environmental Research – UFZ, Leipzig, Germany*

<sup>3</sup>*Department of Chemistry, University of Torino, Torino, Italy*

**Background**

Sulfamethoxazole (SMX) represents sulfonamide antibiotics (SAs) widely used in veterinary and human medicine. SMX is incompletely metabolized and enters the environment with wastewater discharge, animal manure and aquaculture. SMX is frequently detected in wastewater treatment plants, surface and ground water. In the environment it undergoes different degradation processes, such as biodegradation and photodegradation.

Understanding of SA's removal routes is crucial for an assessment of their environmental impact. Compound specific stable isotope analysis (CSIA) can provide additional information on the organic contaminants' transformation processes in complex environments. In CSIA, the changes in isotope composition of the parent compound are monitored during (bio)transformation processes and the isotope enrichment of the investigated contaminant provides an evidence for its (bio)degradation without a need of metabolite analysis.

**Objectives**

This research aims to evaluate the applicability of CSIA for the assessment of SMX transformation pathways. Therefore, the isotope fractionation of SMX during biotic degradation by *Microbacterium* sp. strain BR1 and abiotic transformation via direct photolysis was determined.

**Methods**

Bio- and photodegradation assays; HPLC; LC-IRMS; quantification of enrichment factors

**Conclusions**

A significant difference in isotope fractionation during biotic and abiotic SMX decomposition was observed, showing that CSIA has a potential for distinguishing these two degradation processes. Isotope fractionation during direct photolysis was variable and depended on pH of the solution.

This work shows a new application for CSIA - monitoring of sinks, sources and environmental behaviour of water-soluble contaminants, among which pharmaceuticals are of particular concern.

#### **BIOREMEDIATION OF DRILL CUTTINGS BY HALOPHILIC BACTERIA**

M. Rezaei Somee<sup>1</sup>, M. Didari<sup>1</sup>, M.A. Amoozegar<sup>1</sup>, M. Shavand<sup>2</sup>, S.M.M. Dastgheib<sup>2</sup>

<sup>1</sup>*Extremophiles Lab. Department of Microbiology,*

*Faculty of Biology College of Science University of Tehran, Tehran, Iran*

<sup>2</sup>*Microbiology and Biotechnology Research Group,*

*Research institute of petroleum industry (RIPI), Tehran, Iran*

#### **Background**

Exploration and drilling of oil requires the use of drilling fluid to lubricate and cool the drill bit. Oil based muds (OBMs) containing diesel, are preferred drilling fluids. After mixing with drill cuttings, OBMs form complex industrial wastes containing hydrocarbons and brine. Bioremediation is a promising alternative to physicochemical methods for cleaning up drilling wastes.

#### **Objectives**

The goal of this study was to isolate halophilic bacterial consortium capable of degrading diesel oil in drilling muds and evaluating their applicability in the lab scale drill cuttings microcosm.

#### **Methods**

Between 10 microbial consortia isolated from different saline environments, the best consortium was isolated from Qom sample which grew very well on Bushnell Haas medium containing diesel with the bacterial count about  $1.9 \times 10^{15}$  CFU/ml after 96h of incubation. For evaluating the applicability of the consortium in bioremediation of drill cuttings, it was mixed by 50% of fine sands or biological active soil in the lab scale microcosms and the effect of consortium inoculation was compared with corresponding un-inoculated control for three month.

#### **Conclusions**

The Measurement of the amount of remaining pollutant (TPH) after 3 month showed that the most degradation rate (40%) belonged to the microcosm containing 50% fine sand and consortia inoculation. Sequencing of 16S rRNA gene revealed that the dominant strain of the consortium belonged to the *Dietzia* genus. It could be concluded that bioaugmentation is useful for remediation of drill cuttings when the cuttings mixed with fine sand which has a weak microbial flora and allowing the better growth of inoculated consortium.

**ISOLATION AND CHARACTERIZATION OF CONFLUENTIMICROBIUM SP. NS6, A NEW NAPHTHALENE-DEGRADING BACTERIUM, ISOLATED FROM AN OIL-CONTAMINATED TIDAL FLAT**

H. Jeong<sup>1</sup>, H. Jin<sup>1</sup>, S. Jung<sup>1</sup>, C. Jeon<sup>1</sup>

<sup>1</sup>life science, chung-ang university, Seoul, Korea

**Background**

Polycyclic aromatic hydrocarbons (PAHs) are great environmental concerns because of their persistence, toxicity, and carcinogenicity. Many studies for bacteria capable of PAH degradation have been reported in seawater, but PAH-biodegrading bacteria in tidal flats have been rarely explored.

**Objectives**

The purpose of this study was to isolate strains NS6 as a novel PAH degrader capable of PAH degradation in tidal flats and characterize its physiological and PAH-biodegrading properties.

**Methods**

We established a slurry type enrichment system based on tidal flat sediment and seawater using naphthalene as a sole carbon and energy source. The enrichment culture was spread on marine agar (MA) and incubated at 25°C for 2 days. Colonies grown on MA were characterized phylogenetically based on their 16S rRNA gene sequences and the naphthalene degradation abilities were evaluated in seawater, tidal flat slurry, and ONR7a. Finally, a strain showing a good naphthalene degradation property was isolated and its PAH degradation properties and genes were characterized.

**Conclusions**

A naphthalene degrading bacterium, designated strain NS6, was isolated from the slurry type enrichment and classified into a member of *Confluentimicrobium* based on its 16S rRNA gene sequence. *Confluentimicrobium* sp. NS6 degraded PAH compounds quickly in all tested media. Naphthalene dioxygenase gene of *Confluentimicrobium* sp. NS6 was successfully amplified by only NDO 201 primer set, which suggested that strain NS6 may metabolize naphthalene via a *nah* catabolic pathway alike *Rhodococcus*. In addition, the PAH degradation properties, physiologies, and PAH degradation gene structure of strain NS6 will be investigated and discussed in detail in the poster section.

## **OXIDATION OF AROMATIC COMPOUNDS BY VERSATILE PEROXIDASE (VP1) OF PLEUROTUS OSTREATUS UNDER MN<sup>2+</sup>-DEFICIENCY**

D. Knop<sup>1</sup>, D. Levinson<sup>1</sup>, O. Yarden<sup>1</sup>, Y. Hadar<sup>1</sup>

<sup>1</sup>Department of Plant Pathology and Microbiology,

The Hebrew University of Jerusalem The Faculty of Agriculture, Rehovot, Israel

### **Background**

The use of white rot fungi such as *Pleurotus ostreatus* and their lignin-modifying enzymes has become an effective treatment for various organic soil and water pollutants. The manganese peroxidase gene family (*mnps*) is a major part of the ligninolytic system of *P. ostreatus*. This gene family is comprised of nine genes encoding short manganese peroxidases (short-MnPs) or versatile peroxidases (VPs). The VPs contain unique active sites which are responsible of direct oxidation (in the absence of Mn<sup>2+</sup>) of various aromatic compounds.

### **Objectives**

Here we study the oxidation mechanisms of aromatic compounds by VP1 of *P.ostreatus*.

### **Methods**

We show that in Mn<sup>2+</sup>-deficient GP medium *vp1* (encoding VP1) has a key and non-redundant function. We used the azo-dye Orange II (OII) as a model contaminate, its decolorization occurs only during the idiophase where the abundance transcripts of *mnps* indicate that *vp1* is the predominantly expressed and a  $\Delta vp1$  strain showed a drastic reduction in the decolorization. Three degradation metabolites were identified by LC-MS indicating both asymmetric and symmetric enzymatic cleavage of the azo bond. The presence of asymmetric cleavage diminishes the toxicity level of the degradation products. To better understand mechanisms of degradation and detoxification we purified and characterized VP1. The purified enzyme degraded 60% of OII (50μM) within the first min and continued up 90% within 6 min.

### **Conclusions**

The non-specific oxidation properties of VP1 and its unique ability to degrade organic compound in the absence of Mn<sup>2+</sup> suggest that it may have potential applications for treatment of contaminated water.

**FUNGAL DEGRADATION OF POLYSTYRENE AND ITS ANALOGUE  
POLYSTYRENE SULFONATE - IMPLICATIONS ON PLASTICS WASTE  
BIOREMEDIATION**

M.C. Krüger<sup>1</sup>, A. Prager<sup>2</sup>, B. Abelf, D. Schlosser<sup>1</sup>

<sup>1</sup>*Environmental Microbiology, Helmholtz Centre for Environmental Research - UFZ,  
Leipzig, Germany*

<sup>2</sup>*Chemical Department, Leibniz Institute of Surface Modification (IOM), Leipzig,  
Germany*

**Background**

Accumulation of synthetic polymers in the environment is cause for concern, as they have been associated with various negative effects on ecosystem health, especially marine systems. Knowledge on biodegradation pathways of conventional polymers is very limited, but it is known that these compounds are hardly biodegradable.

**Objectives**

Here, we investigated whether fungi causing white and brown rot of wood are capable of degrading the widespread polymer polystyrene (PS) as well as its water-soluble analogue polystyrene sulfonate (PSS). Their well-known extracellular oxidation capabilities made them promising candidates for the degradation of these recalcitrant substrates.

**Methods**

PSS analysis by size exclusion chromatography revealed that it was practically inert to white-rot fungi, but vulnerable to various brown-rot strains, which caused strong depolymerisation leading to molecular mass reductions of more than 90 %. Detailed investigations pointed to Fenton reactions driven by fungal hydroquinones as agents of depolymerisation. Solid PS films were significantly more recalcitrant, as no changes in their bulk properties were observable after long periods of fungal treatment. Indications of biodegradation only came from surface property measurements, which revealed increased hydrophilicity through slightly decreased water contact angles. Investigations by X-ray photoelectron spectroscopy revealed that surface oxygen content had increased significantly in fungi-treated samples.

**Conclusions**

These results demonstrate that biodegradation of recalcitrant synthetic polymers is, in principle, possible. However, the different observations between PS and PSS indicate that biological attack on the solid polymer proceeds extremely slowly, raising questions about the feasibility of PS waste biodegradation.

#### FUNCTIONAL ANALYSIS OF A PLASMID-BORNE ALKYL SULFATE DEGRADATION MODULE OF *PSYCHROBACTER* SP.

*R. Lasek*<sup>1</sup>, *D. Bartosik*<sup>1</sup>

<sup>1</sup>*Department of Bacterial Genetics - Institute of Microbiology,  
Faculty of Biology - University of Warsaw, Warsaw, Poland*

#### Background

Plasmid pP62BP1 (34.5 kb), harboured by strain *Psychrobacter* sp. DAB\_AL62B isolated from ornithogenic deposits in Spitsbergen (Svalbard Archipelago, Norway), was found to carry a phenotypic module, named SLF, which consists of four open reading frames (*slfCHSL*) encoding putative catabolic enzymes and a gene (*slfR*) for transcriptional regulator of AraC/XylS family. Based on the comparative *in silico* analyses, the module was predicted to take part in the metabolism of alkyl sulfates, e.g. sodium dodecyl sulfate (SDS), a popular anionic surfactant.

#### Objectives

The aim of our work was to perform a functional characterization of the SLF module both in native host and in other bacterial strains as well as to elucidate the regulatory mechanism of the *slfRCHSL* genes expression.

#### Methods

Qualitative and quantitative SDS degradation assays were designed based on the properties of Stains-All, a carbocyanine dye. Promoter strength was examined in  $\beta$ -galactosidase activity assays. Transcriptional organization of the module was characterized with the use of reverse transcription PCR.

#### Conclusions

Growth experiments revealed that 0.17 mM concentration of SDS in the medium is sufficient to exert bacteriostatic effect on several tested *Psychrobacter* spp. strains. Nonetheless, the pP62BP1 containing strain was capable of the complete SDS degradation in these conditions. The cloning of the whole SLF module and its *slfR*-deficient derivative into *Escherichia coli* TG1 resulted in obtaining transformants able to degrade SDS. The molecular studies showed that the activity of the *slfCHSL* operon is dependent on SlfR protein which acts as a negative transcriptional regulator.

#### **MOLINATE BIOREMEDIATION STRATEGY USING A MICROENCAPSULATION APPROACH**

A.R. Lopes<sup>1</sup>, V.M. Sousa<sup>1</sup>, B.N. Estevinho<sup>1</sup>, A.M. Paiva<sup>1</sup>, J.P. Leite<sup>2</sup>, F. Ferreira-da-Silva<sup>2</sup>, L.M. Gales<sup>2</sup>, F. Rocha<sup>1</sup>, O.C. Nunes<sup>1</sup>

<sup>1</sup>LEPABE- Dpto. Engenharia Química,

Faculdade de Engenharia - Universidade do Porto, Porto, Portugal

<sup>2</sup>IBMC, Instituto de Biologia Molecular e Celular da Universidade do Porto, Porto, Portugal

#### **Background**

Molinate is a thiocarbamate herbicide used in rice cultivation to control grass weeds, however its use had led to environmental contamination, being critical the establishment of remediation procedures. A mixed culture has been described as being able to mineralize molinate as the sole source of carbon, nitrogen and energy [1, 2], primarily, by the activity of molinate hydrolase (MolA) [3], encoded by *Gulosibacter molinativorax* ON4<sup>T</sup>. Previous studies, using soil microcosms, have demonstrated that a bioaugmentation strategy using the mixed culture was a feasible approach to bioremediate paddy soils contaminated with molinate [4].

#### **Objectives**

To improve the bioremediation strategy, we aimed at microencapsulating ON4<sup>T</sup> cells or MolA, using a spray-drying process that uses biopolymers as encapsulating agent [5].

#### **Methods**

Several encapsulating agents (sodium and calcium alginate, arabic gum, chitosan and modified chitosan) were used. The spray-drying product yield was about 50% for all the agents. The metabolic activity of the microencapsulated cells was proven by a qualitative colorimetric method using a redox dye (tetrazolium violet).

#### **Conclusions**

There was a linear correlation between the amount of encapsulated cells and the colour development intensity. The feasibility of using optimized microencapsulated biomaterial will be tested in contaminated soil and water using a microcosm approach.

Kurdistan University of Medical Sciences, Sanadaj, Iran

<sup>2</sup>Microbiology, Alborz University of Medical Sciences, Karaj, Iran

<sup>3</sup>Entomology, Hamadan University of Medical Sciences, Hamadan, Iran

### **Background**

With the emergence of microorganisms resistant to multiple antimicrobial agents there is increased request for promotion of disinfection methods.

### **Objectives**

Since ZnO nanoparticles (ZnO-NPs) exhibit strong antibacterial activities on a broad spectrum of bacteria the aim of this study was to evaluate the antimicrobial activity of ZnO-NPs against *pseudomonas aeruginosa* as a model for gram-negative bacteria.

### **Methods**

Muller Hinton broth was used as a growing medium for *pseudomonas aeruginosa*. Photocatalytic experiment was carried out in a laboratory-scale batch reactor with low pressure ultraviolet irradiation (380 nm). Different experimental parameters such as amount of ZnO-NPs, contact time, inorganic and organic substances and pH on photocatalytic inactivation of *pseudomonas aeruginosa* cells have been studied. An initial *pseudomonas aeruginosa* concentration of 10<sup>8</sup> CFU/mL was used for all experiments.

### **Conclusions**

Result showed that, almost all the initial *pseudomonas aeruginosa* cell (10<sup>8</sup> CFU/ml) was inactivated in 60 min in the presence of 2 g/l ZnO-NPs. Photocatalytic inactivation of bacteria was found to follow first order kinetics. The initial pH of the water did not play an important role on the inactivation rate within a range of 6–8 pH units. The amount of photocatalyst also plays an important role in photocatalytic inactivation rate. As the result showed increasing the photocatalyst amount provided more rapid inactivation. Addition of some inorganic ions to the suspension affects the sensitivity of *pseudomonas aeruginosa* and caused to retard the inactivation rates.

Since the sensitivity of *pseudomonas aeruginosa* to photocatalytic treatment was fairly good, it is therefore, recommended to use this nano-particle for water treatment.

**ADAPTATION TO AROMATIC HYDROCARBONS INVOLVES A NEW HYBRID TWO-COMPONENT REGULATORY SYSTEM IN AZOARCUS SP. CIB**

Z. Martín<sup>1</sup>, C. Baraquet<sup>2</sup>, C.S. Harwood<sup>2</sup>, M.T. Zamarro<sup>3</sup>, E. Díaz<sup>3</sup>

<sup>1</sup>*Environmental Biology, (CIB-CSIC), Madrid, Spain*

<sup>2</sup>*Microbiology, University of Washington, Seattle, USA*

<sup>3</sup>*Environmental Biology, CIB-CSIC, Madrid, Spain*

**Background**

The catabolic processes performed in anaerobiosis are becoming of great environmental interest because many anoxic ecosystems are frequently contaminated with aromatic compounds. The facultative anaerobe  $\beta$ -proteobacterium *Azoarcus* sp.CIB has been used as model system to study basic aspects on the biochemistry and genetics underlying the anaerobic metabolism of several aromatic compounds. Within the operon responsible for the anaerobic degradation of toluene, we identified an orphan gene, *tolR*, without homologues. The TolR protein shows an atypical architecture which corresponds to a new hybrid two-component system (HTCS), where the sensor histidine-kinase and the c-di-GMP phosphodiesterase-containing response regulator (RR) components are fused in a single polypeptide.

**Objectives**

The main objective was to demonstrate that TolR constitutes a new HTCS involved in anaerobic adaptation to aromatic hydrocarbons in *Azoarcus* sp.CIB

**Methods**

An *in vivo* approach for confirming the c-di-GMP phosphodiesterase activity of the *tolR* gene was done using a *lacZ*-based *P. aeruginosa* reporter strain. *In vitro* approaches by using purified TolR and truncated forms were used to demonstrate toluene-induced autokinase and transphosphorylation activity. Transcriptomic studies were done to identify genes involved in the TolR-mediated response to aromatic hydrocarbons.

**Conclusions**

TolR encodes a unique HTCS whose RR is not a transcriptional regulator but a c-di-GMP phosphodiesterase. We demonstrate for the first time the effector-dependent induction of the intramolecular phosphorelay in HTCS. Transcriptomic studies confirmed that TolR is involved in a signalling network that controls the morphological, metabolic and stress response programs. The toluene-dependent control of c-di-GMP levels represents an unprecedented mechanism of bacterial adaptation to aromatic hydrocarbons.

## **BIODEGRADATION POTENTIAL OF *PENICILLIUM* SP. ISOLATED FROM SOUTH CHINA SEA**

A. Ngadin<sup>1</sup>, R. Sundaresan<sup>1</sup>, L. Wong<sup>2</sup>, S. Hasan<sup>1</sup>

<sup>1</sup>*School of Food Sciences and Technology, Universiti Malaysia Terengganu, Kuala Terengganu, Malaysia*

<sup>2</sup>*School of Fisheries and Aquaculture Sciences, Universiti Malaysia Terengganu, Kuala Terengganu, Malaysia*

### **Background**

Some halophiles fungal genera were found from sea sediment samples are potentially play an important role in nutrient regeneration cycles as decomposers.

### **Objectives**

In this study, three genera of microfungi derived from South China Sea were isolated as *Penicillium*, *Aspergillus* and *Talaromyces* in order to identify the fungal saprotrophic properties.

### **Methods**

For the first stage of investigation by using dermatophyte test medium (DTM), the results showed that only the ascomycete *Penicillium* sp. highly potential as saprophytic microfungi. This fungus was used to observe their early thallus development *in vitro* and to determine a degradation potential of the textile dyes Trypan blue (TB), Methyl orange (MO), Sudan III (S3), Congo red (CR) and Bromocresolgreen (BG) in broth culture.

### **Conclusions**

*Penicillium* sp. displays a distinctive morphological growth, produced an orange pigment in all different media as an additional features of the strain. In contrast, there were significant differences in physiological tests of *Penicillium* sp. such as thermophilic osmophilic, pH, salinity, xerotolerant and nitrogen stress. In the presence of textile dyes in liquid media was able decolorized by *Penicillium* sp. Thus, this study shows that halophilic *Penicillium* sp. from sediment of South China Sea is hereby reported for the first time and will be used as bio-indicator of water pollution and also in biological wastewater treatment. In addition this investigation also demonstrated the need of extra and intracellular enzymes associated to decolorization and biodegradation assays.

<sup>3</sup>R&D, EFACEC – Engenharia e Sistemas S.A., Maia, Portugal

#### Background

Biogas resultant from the anaerobic treatment of sludge is composed mainly of CH<sub>4</sub> and CO<sub>2</sub>. H<sub>2</sub>S, a minor component, is of particular concern due to its corrosive and environmentally hazardous properties. Some microorganisms are able to perform enzymatic oxidation of H<sub>2</sub>S to sulfur and/or sulfate. Biological treatment using these microorganisms can be an alternative to physical/chemical processes, avoiding the production of secondary waste.

#### Objectives

This work aims at the characterization of enzyme(s) responsible for H<sub>2</sub>S oxidation in *Pseudomonas* sp.

#### Methods

Isolates A9, B9 and C1, identified as *Pseudomonas* spp., were isolated through enrichment from wastewater treatment plant deodorant bioreactor supplied with H<sub>2</sub>S streams. These strains were screened for the presence of genes responsible for H<sub>2</sub>S oxidation by PCR using degenerated primers for group II *sulfide quinone:oxidoreductase*. Fragments with the expected size were purified from the gel and subjected to sequencing. Translated sequences were compared using the BLAST software. Total protein profiles were screened by SDS-PAGE, before and after the addition of H<sub>2</sub>S. Activity tests were conducted using crude cell extract as catalyst and measuring the formation of sulfate as the reaction product.

#### Conclusions

The amplified fragment from isolate A9 showed 51% identity with an *oxidoreductase* from *Pseudomonas* sp. M1, indicating that this bacterium has the machinery required to the desired activity. The protein profile of the strains when grown in the presence H<sub>2</sub>S differ from the profile of the same strain grown without sulfide.

### **Background**

The biodegradability of PBAT (poly(butylene adipate-co-butylene terephthalate)) under aerobic conditions has been examined in several studies. However, there is considerably less known about PBAT biodegradation in anaerobic environments.

### **Objectives**

Amongst others *Clostridium* species are known to be typically present during naturally occurring anaerobic degradation processes of polymers (e.g. in biogas plants). Hence, various *Clostridium* species were in-silico screened for esterases that are possibly active on synthetic polyesters like PBAT.

### **Methods**

First, a selection of identified hydrolases from *Clostridium* species were successfully expressed in *E. coli* BL21-Gold(DE3). The activity of these esterases was confirmed on the soluble standard substrate *p*-nitrophenyl butyrate as well as on the PBAT polymer. All esterases were characterized in detail including the determination of their crystal structure or modeling of the proteins. The crystal structure of one promising esterase revealed the presence of a metal ion that lies deep beneath the protein surface. Furthermore, *Clostridium* cultures were tested for their ability to express these active and naturally occurring enzymes in situ and degrade the PBAT polymer.

## Conclusions

We were able to prove that the novel hydrolases from *C. botulinum* and *C. hathewayi* hydrolyze the aliphatic-aromatic polyester PBAT. These enzymes are promising candidates for industrial applications or pollutant degradation. Furthermore the study provides information about these anaerobic strains and their naturally occurring enzymes.

## **USE AND IMPACT OF $\text{MnO}_2$ MICROPARTICLES FOR SULFIDE SCAVENGING IN MICROBIAL BROTHS**

H. Roume<sup>1</sup>, J. Engels<sup>1</sup>, K. Suetens<sup>2</sup>, K. Verbeker<sup>2</sup>, S. Devkota<sup>3</sup>, M. Devolder<sup>4</sup>, K. Rabaey<sup>1</sup>

<sup>1</sup>Laboratory of Microbial Ecology and Technology, Ghent University, Ghent, Belgium

<sup>2</sup>Department of Materials Science and Engineering, Ghent University, Ghent, Belgium

<sup>3</sup>Joslin Diabetes Center, Harvard Medical School, Boston, USA

<sup>4</sup>Department of Mechanical Engineering, KULeuven, Leuven, Belgium

### **Background**

Hydrogen sulfide ( $\text{HS}^-$ ) is ubiquitously present in many waste streams originating from industrial activities as well as in sewage. It needs to be removed, as it can be toxic to bacteria, induces concrete corrosion and forms an odour nuisance.  $\text{MnO}_2$  has been proposed for  $\text{HS}^-$  adsorption and oxidation, the addition of such particles to microbial broths may enable selective sulfide scavenging. However potentially negative effects of addition of  $\text{MnO}_2$  microparticles (MPs) on microbial metabolism may occur.

### **Objectives**

Therefore, we evaluated the efficiency of this  $\text{MnO}_2$  MPs based  $\text{HS}^-$  removal strategy and test the effect of the particles and the sulfide scavenging on bacterial growth and microbial community activity.

### **Methods**

Abiotic batch tests were set up to test impact of pH on  $\text{HS}^-$  removal.  $\text{HS}^-$  removal rate after 24h at pH 7.2 was twice that at pH 10.5. Scanning electron microscopy with energy dispersive X-ray spectroscopy showed the presence of sulfur as well as MnS on the particle surface. The effect of  $\text{HS}^-$ ,  $\text{MnO}_2$  MPs and mixtures of both on the growth of single bacterial strains, and mixed microbial community activity were assessed using an optical density microplate reader placed into an anaerobic chamber and biochemical methane potential assays respectively.

### **Conclusions**

The presence of  $\text{MnO}_2$  MPs did not affect bacterial growth under any of the conditions tested. Inhibitory effects due to presence of  $\text{HS}^-$  on bacterial growth were observed, upon addition of  $\text{MnO}_2$  MPs normal growth could be restored. We finally observed that a mixture of  $\text{HS}^-$  and  $\text{MnO}_2$  MPs positively impacted methanogenic activity.

#### IN STREPTOMYCES, STRONG ANTIBIOTIC PRODUCTION CORRELATES WITH EXTENSIVE STORAGE LIPIDS DEGRADATION AND HIGH ATP GENERATION.

P. Le Maréchal<sup>1</sup>, P. Decottignies<sup>1</sup>, C. Esnault<sup>2</sup>, A. Smirnov<sup>2</sup>, T. Dulermo<sup>2</sup>, M. Froissard<sup>3</sup>, A. Deniset-Besseau<sup>4</sup>, M.J. VIROLLE<sup>5</sup>

<sup>1</sup>Proteomic, IBBMC, Orsay, France

<sup>2</sup>Microbiology, IGM, Orsay, France

<sup>3</sup>INRA, IJPB, Versailles, France

<sup>4</sup>Physical Chemistry, LCP, Orsay, France

<sup>5</sup>Microbiology, Institute of Genetic and Microbiology, Orsay, France

#### Background

Some *Streptomyces* strains produce antibiotics and others don't. Why? For instance *S. lividans* and *S. coelicolor* are phylogenetically closely related strains possessing the same functional antibiotic biosynthetic pathways but *S. lividans* produces antibiotics at low level whereas *S. coelicolor* produces them at high levels. Interestingly, a dramatic overproduction of antibiotics occurred in *S. lividans* upon interruption of the *ppk* gene. This mutant strain experiences energetic stress (ATP deficit) since Ppk regenerates ATP from ADP and polyphosphate. However, the role of the Ppk in relation to the regulation of antibiotic biosynthesis remains unclear.

#### Objectives

To better understand it we assess the global impact of strong antibiotic production on the cellular metabolism.

#### Methods

To do so proteomic and lipidomic analysis were conducted and the cellular content in polyphosphate, ATP/ADP and free Pi was assayed throughout growth of the three strains of interest grown in phosphate limitation or proficiency.

#### Conclusions

Our results revealed that an active degradation of storage lipids (TriAcylGlycerol, TAG) was taking place in the antibiotic producing strains. TAG degradation generates precursors used directly or indirectly for antibiotics biosynthesis as well as numerous reduced co-factors (FADH<sub>2</sub>) whose re-oxidation by the respiratory chain yields high levels of ATP. Whereas the *ppk* mutant likely mobilizes its storage lipids to re-

establish its energetic balance, the reason of the extensive TAG degradation taking place in *S. coelicolor* is still not understood.

**Background**

Chlorendic acid (1,4,5,6,7,7-hexachlorobicyclo[2.2.1]-hept-5-ene-2,3-dicarboxylic acid, known as HET acid, or Hetron 92) has been identified in the past as the dead-end product of the biodegradation of the cyclodiene pesticides Aldrin, Endrin, Dieldrin, Endosulfan, Chlordane, and Heptachlor. On the other hand, this compound is still being produced as a flame retardant, and used in respective materials and corrosion-resistant equipment. Chlorendic acid has been considered as non-biodegradable until today.

**Objectives**

Although the hexachlorocyclopentadiene moiety of the compound is highly halogenated and does not carry any hydrogen atom, its dichloroethene substructure may provide the side of bacterial attack by the mechanism of anoxic dehalogenation as known from tetrachloroethylene or polyhalogenated aromatics (halo-respiration), and thus represent the initial side of a biochemical reaction. Further steps of dehalogenation then may proceed aerobically as, for instance, in the catabolic pathway of hexachlorocyclohexane (HCH, Lindane).

**Methods**

We started enrichment experiments with sediments from the River Elbe (Hamburg, Germany) the former contamination of which by pesticides from production plants of chemicals has been well documented, and established a gradient bioreactor system with an anaerobic zone at the bottom towards an aerobic zone at the top. From the latter we could already isolate the dominant bacterium responsible for the mineralization of the (almost) dehalogenated carbon backbone. 16S rDNA analysis revealed this species as 98% identical to *Pseudomonas aeruginosa*.

**Conclusions**

Analyses of the 16S rRNA gene sequences in the anoxic and transition zones will determine the bacterial community structure involved in the catabolic sequence. Identification of intermediates of the combined anaerobic-aerobic pathway is underway.

**Background**

Contamination with pharmaceuticals is an emerging environmental problem. Most pharmaceuticals are only partially eliminated in biological wastewater treatment processes, leading to contamination of ground- and surface water. Among them, antibiotics are of particular concern due to potential spread of antibiotic resistance. Sulfamethoxazole (SMX) represents sulfonamides, which belong to most prescribed and consumed antibiotics worldwide. Only a few microbial strains using SMX as a sole carbon source have been isolated and metabolic pathways for most of them have not been described.

The nootropic drugs are a new group of emerging contaminants, very popular these days because of their increasing use as pharmaceuticals and illicit drugs. Some of them, e.g. piracetam and ritalinic acid, have been recently detected in drinking water but so far their potential biodegradation has received very little attention.

**Objectives**

This research aims at isolation and characterization of novel microbial strains capable to degrade SMX, piracetam and ritalinic acid.

**Methods**

Enrichment and isolation of strains was carried out under aerobic conditions using various environmental samples as inocula: wastewater, activated sludge, soil, birds feces etc. Degradation is monitored by HPLC-DAD; new method for ritalinic acid and piracetam have been established; 16S rRNA analysis was performed; radio assays with <sup>14</sup>C labeled ritalinic acid will be carried out.

**Conclusions**

Two novel strains capable of SMX degradation have been isolated. Enrichment cultures with piracetam and ritalinic acid are active and the isolation of strains is ongoing. It is a first attempt to obtain the strains growing on nootropic drugs.

## **DEGRADATION OF TRICLOSAN AND TRICLOCARBAN BY A WASTEWATER MICROORGANISM**

S. Mulla<sup>1</sup>, C. Yu<sup>1</sup>

<sup>1</sup>Key Laboratory of Urban Pollutant Conversion,

Institute of Urban Environment Chinese Academy of Sciences, Xiamen, China

### **Background**

Since last several decades, biocides like triclosan and triclocarban have been used as a common ingredient in many synthetic products especially in industrial and personal care products. Hence, the widespread use of triclosan and triclocarban has raised major concern over their impact on eco-geological system.

### **Objectives**

We have isolated and identified a triclosan-degrading bacterium from wastewater treatment plant (WWTP) named as *Sphingomonas* sp. strain YL-JM2C.

### **Methods**

Response surface methodology was used to understand the suitable conditions for the degradation of triclosan in strain-YL JM2C. The bacterium can efficiently degrade triclosan (5 mg L<sup>-1</sup>) with biomass between 0.1-0.3 g L<sup>-1</sup> at 30-35 °C with pH 7-8. By GC-MS analysis, the intermediates of triclosan biodegradation were identified as 2,4-dichlorophenol, 2-chlorohydroquinone and catechol. Tracking experiment using <sup>13</sup>C labeled triclosan confirmed that the <sup>13</sup>C labeled triclosan was completely mineralized into carbon dioxide by strain YL-JM2C, and the phospholipid fatty acids (PLFAs) extracted from bacterial cells showed that part of labeled carbon from <sup>13</sup>C labeled triclosan was incorporated into the strain's fatty acids.

### **Conclusions**

These results indicated that the bacterium was able to utilize triclosan as a carbon source. We also observed that the bacterium was also able to degrade 30 to 35% of triclocarban (4 mg L<sup>-1</sup>). In *Sphingomonas* sp. strain YL-JM2C, triclocarban was initially hydrolyzed into 3,4-dichloroaniline and 4-chloroaniline. 3,4-Dichloroaniline was further transformed to 4-chlorocatechol via 4-chloroaniline. As per our knowledge, this is the first report of bacterial degradation of triclocarban by a pure isolated bacterial strain.

<sup>2</sup>Genome Analysis Platform, CIC bioGUNE & CIBERehd, Derio, Spain

**Background**

Fungi interact with their environment by means of secreted proteins to obtain nutrients, elicit responses and modify their surroundings. Consequently, lifestyle influences the set of fungal secreted proteins.

**Objectives**

To perform a combined bioinformatics-transcriptomics study of the secretome of the basidiomycete *Pleurotus ostreatus* and to explore the conservation of these secreted proteins across the Basidiomycota phylum

**Methods**

We identified bioinformatically the set of secretable proteins in two monokaryotic strains (haplotypes) of the white-rot basidiomycete *P. ostreatus* (PC9 and PC15) using the web pipeline SECRETOOL [1]. Then, we performed two RNA-seq analyses to study the relationship between the functional profile of the predicted secretome and the expression level of each group. Finally, we used the set of proteins secreted by *P. ostreatus* as a query to search for similar proteins in the fungal genomes released in JGI Mycocosm[2]

**Conclusions**

**Figure 1:** Dendrogram showing several basidiomycetes arranged by presence of similar proteins (E-value<e-20) to PC15 predicted to be secreted proteins

538 and 554 protein models were predicted to be secreted (4.41% and 4.77% of PC9 and PC15 gene models, respectively). The functional annotation of these proteins revealed the unknown (37.2%), glycosyl hydrolases (26.5%) and red-ox enzymes (11.54%) as the main functional groups, in a similar distribution for the two strains. The expression level of these groups further enhances the relevance of the unknown group and was significantly different in the two strains (revealing different responses to the same environment). Furthermore, the presence of similar proteins to *P. ostreatus* secreted proteins in other basidiomycetes was used to cluster them into

groups coherent with their particular lifestyles rather than with their corresponding phylogenetic positions.

## **NEW INSIGHTS INTO THE T6SS OF PSEUDOMONAS AERUGINOSA**

L. Allsopp<sup>1</sup>, A. Filloux<sup>1</sup>

<sup>1</sup>Life Sciences CMBI, Imperial College London, London, United Kingdom

### **Background**

*Pseudomonas aeruginosa* is a gram-negative opportunistic pathogen capable of living in a wide variety of environmental niches and is the third most common cause of all hospital-acquired infections. *P. aeruginosa* utilises a range of secretion systems and virulence factors to enable it to prosper. The Type VI Secretion System (T6SS) is one such factor. This nanomachine can modulate invasion of epithelial cells and is widely known for its ability to facilitate the delivery of effector proteins into both Eukaryotic cells and Bacterial competitors.

### **Objectives**

The majority of *P. aeruginosa* strains have three complete T6SS clusters [H1-, H2-, and H3-T6SS] however additional 'orphan' genes or short operons are present in the *P. aeruginosa* genomes, which have the characteristics of T6SS components. In this study we have employed a range of molecular microbial techniques to further investigate components of the T6SS and related systems.

### **Methods**

Through the construction of *lacZ* fusions, transposon mutagenesis, specific gene deletions, complementation and labelling with V5 tags we have identified new secreted products and mechanistic insights that contribute to the function of the *P. aeruginosa* T6SS. We also characterized global regulatory networks that are instrumental to the expression of genes encoding either core components of the T6SS machine or cognate T6SS effectors.

### **Conclusions**

Overall secretion systems are of vital importance for Bacteria to interact with their environment and cause infection. A detailed knowledge of the mechanisms of secretion combined with an understanding of the role of the secreted factors should provide the basis for the development of new therapies to combat bacterial infections.

## **EXPRESSION OF THE MENINGOCOCCAL AUTOTRANSPORTER AUTB AND ITS IMPACT ON BIOFILM FORMATION**

*P. Rodriguez<sup>1</sup>, D. Tajouri<sup>1</sup>, S. Cano<sup>1</sup>, J. Tommassen<sup>1</sup>, J. Arenas<sup>1</sup>*

*<sup>1</sup>Molecular Microbiology, Microbiology, Utrecht, Netherlands*

### **Background**

Autotransporters are secreted proteins of Gram-negative bacteria often involved in virulence. They consist of a translocator domain that inserts as a  $\beta$ -barrel in the outer membrane and a fused passenger domain that is translocated across the outer membrane. Genomes of the human pathogen *Neisseria meningitidis* contain eight autotransporter genes. Seven have been characterized to a certain extent, but the autotransporter AutB remains poorly studied. Previous studies suggested that the *autB* gene is a pseudogene.

### **Objectives**

Our objective was to analyze whether AutB can be expressed and to elucidate its possible function.

### **Methods**

In this study we used a combination of genomic and proteomic assays to determinate the expression of the autotransporter. Included were also diverse functional assays to analyse its function.

### **Conclusions**

Bioinformatics analysis of available genome sequences indicated that AutB expression is prone to phase variation, and can be inhibited by the presence of premature stop codons or other genetic disruptions. However, several genome sequences contain an intact *autB* gene. Western blotting and RT-PCR assays demonstrated the expression of AutB in strains with an intact gene. Proteinase K-accessibility assays evidenced that AutB is secreted but its passenger remains attached to the cell surface. Functional assays revealed the involvement of AutB in biofilm formation in a strain-dependent mode. We conclude that *autB* is a pseudogene only in some strains and that AutB may have a relevant function in the formation of bacterial communities.

<sup>2</sup>transcriptional regulation and mediator, UGSF, Villeneuve d'Ascq, France

<sup>3</sup>system biology of signal transduction, UGSF, Villeneuve d'Ascq, France

**Background**

Many bacterial pathogens use Type Three Secretion System (T3SS) to inject virulence factors, named effectors, directly into the cytoplasm of target eukaryotic cells. Before being translocated, effectors are maintained in a secretion-competent state by interacting with specific chaperones. The molecular mechanism of the recognition process between the effector/chaperone complex and the T3SS is still unclear but a highly conserved hexameric-ring-shaped ATPase localized at the basis of the needle complex has a critical role in the specific recognition process of chaperone-effector complex.

**Objectives**

As previous works showed that chaperones and effectors share structural motifs that could be at the origin of the recognition by TTSS, we investigated the structure of the complex between SopB, and its cognate chaperone SigE that is the form recognized by TTSS.

**Methods**

In this work we performed a biochemical and structural characterization of *Salmonella* SopB/SigE chaperone/effector complex by SAXS.

**Conclusions**

Our results showed that the SopB/SigE complex is assembled in dynamic homo-hexameric-ring-shaped structures with an internal tunnel. In this ring, the chaperone maintains a disordered N-terminal end of SopB molecules, in good position to be reached and processed by the T3SS. This ring dimensionally fits the ring-organized molecules of the injectisome including ATPase hexameric ring; this organization suggests that this structural feature is important for the ATPase recognition by T3SS. As effectors share neither sequence nor structural identity, the quaternary oligomeric structure could constitute a strategy evolved to promote the specificity and efficiency of T3SS recognition.

**DECIPHERING THE MOLECULAR STRUCTURE AND FUNCTION OF VIRB4-LIKE ATPASES IN NUCLEOPROTEIN IMPORT AND EXPORT**

V. Hunusur Rajendra<sup>1</sup>, C. Gruber<sup>2</sup>, K. Zangger<sup>3</sup>, E. L. Zechner<sup>1</sup>

<sup>1</sup>*Microbiology, Institute of Molecular Biosciences, Graz, Austria*

<sup>2</sup>*Plant Sciences, Institute of Plant Sciences, Graz, Austria*

<sup>3</sup>*Organic Chemistry, Institute of Chemistry, Graz, Austria*

**Background**

VirB4-like proteins are associated with all bacterial Type 4 Secretion Systems (T4SS) described to date. These signature ATPases function in assembly of the T4SS channel and biogenesis of extracellular pili. They are also required for translocation of secretion substrates and nucleoprotein uptake during pilus-mediated phage infection.

**Objectives**

Very little is known about the regulation of VirB4-like ATPases in protein trafficking. Our paradigm to study control of VirB4-like ATPases is TraC of the F-like conjugative plasmid R1. Here we test the hypotheses that ATPase activity is controlled by (i) oligomeric state and (ii) intra-molecularly, by auto-inhibition.

**Methods**

Full length and truncated alleles of traC were modified with a strep-tag and evaluated functionally by complementation of conjugative transfer of a  $\Delta traC$  derivative of R1. Multimer formation, nucleotide binding and hydrolysis by purified TraC proteins were measured under various conditions in the presence and absence of protein interaction partners using NMR and biochemical techniques.

**Conclusions**

Full length TraC behaves as a monomer in solution with and without a 20-fold molar excess of non-hydrolysable ATP. This form binds but does not hydrolyze nucleotide. Preliminary data indicates that proteolytic processing of the protein stimulates both the formation of apparent hexamers and enzyme activity.

#### **MOLECULAR INVESTIGATION OF THE BASEPLATE ASSEMBLY OF THE TYPE VI SECRETION SYSTEM OF PSEUDOMONAS AERUGINOSA**

S. PLANAMENTE<sup>1</sup>, O. Salih<sup>2</sup>, E. Manoli<sup>1</sup>, P. Freemont<sup>3</sup>, A. Filloux<sup>1</sup>

<sup>1</sup>*Life science, Centre for Molecular Bacteriology & Infection (CMBI) Imperial College, London, United Kingdom*

<sup>2</sup>*Life science, Centre for Structural Biology Imperial College, London, United Kingdom*

<sup>3</sup>*Department of Medicine, Centre for Structural Biology Imperial College, London, United Kingdom*

### **Background**

The type VI secretion system (T6SS) involves ~13 core proteins and shares similarities with the tail of the bacteriophage T4. The current model of the structural organization of the T6SS suggests that its core components are assembled in several subcomplexes that are associated to form a dynamic phage-like machinery. A first set of T6SS components forms a trans-envelope complex which consists of the two inner membrane proteins TssM and TssL, and the outer membrane lipoprotein TssJ. A second group of T6SS proteins forms the bacteriophage tail-like structure. It includes the components Hcp and VgrG, and the sheath-like structure made of the two proteins TssB and TssC. Hcp proteins are hexameric rings which are able to form a rigid tube capped by the puncturing device made by VgrG proteins. Contraction of the TssB/TssC sheath propels the Hcp-VgrG structure, which ultimately results in the injection of toxins into target cells.

### **Objectives**

The remaining T6SS core components are likely to form what is known as the baseplate structure in the phage. In the T6SS, it connects the tail-like structure to the membrane subcomplex. Functional and structural information about these T6SS proteins as well as their assembly within the machinery remain poorly described.

### **Methods**

Here, we used biochemical and electron microscopy techniques to determine the structure and function of individual components of the T6SS in *Pseudomonas aeruginosa*. Additionally, using a systematic analysis of protein-protein interaction, we determined the interaction network between T6SS proteins.

## **Conclusions**

Overall these data led to propose a comprehensive working model of the T6SS.

**TYPE VI SECRETION SYSTEM AS A VIRULENCE MECHANISM OF MAMMARY PATHOGENIC ESCHERICHIA COLI**

H. Salamon<sup>1</sup>, I. Nissan<sup>1</sup>, E. Nissim-Eliraz<sup>1</sup>, I. Shoval<sup>1</sup>, N. Shpigiel<sup>1</sup>

<sup>1</sup>Koret School of Veterinary Medicine,

The Hebrew University of Jerusalem The Faculty of Agriculture, Rehovot, Israel

**Background**

Mastitis, infection and inflammation of the mammary gland, is a well-known problem in the dairy industry, affecting cows worldwide and causing considerable financial losses. Multiple bacterial species can cause mastitis and *E. coli* is often involved. Despite many years of mastitis research, no efficient measures exist to prevent or treat the disease, and only little is known about specific virulence factors of the bacteria.

**Objectives**

Our goal is to understand the molecular mechanisms of host-pathogen interactions in the mammary gland and relate them to disease processes, in hope that understanding these mechanisms will lead to development of novel tools to combat *E. coli* mastitis.

**Methods**

Using genome sequencing and analysis of six clinical isolates, we found that type VI secretion system (T6SS) gene clusters are present in all. Furthermore, using unbiased screening of strains for reduced colonization, fitness and virulence in our murine mastitis model, we have identified in P4-NR strain a new pathogenicity island encoding the core components of T6SS and its hallmark effectors Hcp, VgrG and Rhs. Next, we have shown that specific deletions of T6SS genes reduced *in vivo* pathogenicity.

**Conclusions**

Based on our results we hypothesize that T6SS is an important virulence mechanism of MPEC. To our knowledge, we are the first to describe relevance of T6SS in the pathogenesis of mastitis. We intend to validate our findings in dairy cows and field strains and study the molecular mechanisms of T6SS associated with MPEC virulence. The identified mechanism may provide new targets for diagnostic, preventive and therapeutic intervention.

<sup>5</sup>General Physics, University of São Paulo, São Paulo, Brazil

<sup>6</sup>Microbiology ICB, University of São Paulo, São Paulo, Brazil

### **Background**

Type IV secretion systems (T4SSs) are multiprotein complexes that transport effector proteins and protein-DNA complexes through bacterial membranes to the extracellular milieu or directly into the cytoplasm of other cells. They are essential for host colonization by many medically important microbes as well as for horizontal transfer of genetic material between bacteria and from bacteria to plants. Many bacteria of the family Xanthomonadaceae, that occupy diverse environmental niches, carry a T4SS with unknown function but with several characteristics that distinguishes it from other T4SSs.

### **Objectives**

The aim of this study is to determine the function of the Xanthomonadaceae T4SS.

### **Methods**

We have used structural biology, spectroscopy, enzymology and novel bacterial competition and secretion experiments to address this question.

### **Conclusions**

The *Xanthomonas citri* (Xac) T4SS provides these cells the capacity to kill other gram-negative bacterial species in a contact-dependent manner. The secretion of one Type IV bacterial effector protein is shown to require a conserved C-terminal domain and its bacteriolytic activity is neutralized by a cognate immunity protein whose 3D structure is similar to peptidoglycan hydrolase inhibitors. This is the first demonstration of the involvement of a T4SS in bacterial killing and points to this special class of T4SS as a mediator of both antagonistic and cooperative interbacterial interactions and therefore an important driving force in the evolution of bacterial species.

## **STUDIES ON THE REGULATION OF TYPE VI SECRETION SYSTEMS IN ESCHERICHIA COLI**

S. Tjaden<sup>1</sup>, M. Berger<sup>1</sup>, U. Dobrindt<sup>1</sup>

<sup>1</sup>*Institute of Hygiene, University Hospital Münster, Muenster, Germany*

### **Background**

Type VI secretion systems (T6SS) are complex protein transport machineries and widespread among pathogenic Gram-negative bacteria. Accordingly, one could assume that they may contribute directly or indirectly to pathogenesis; for example, by targeting eukaryotic host cells or by competing with other bacteria in microbial populations.

### **Objectives**

The genomes of the uropathogenic *Escherichia coli* (UPEC) strains often harbor one or more genomic islands encoding putative T6SSs. As the expression of T6SSs seems to be tightly regulated, most of the secretion systems are inactive under standard laboratory conditions. The screening for potential regulators directing gene expression of T6SSs is a first step to get a better understanding under which conditions these secretion systems may be active and contribute to the fitness and/or pathogenicity of *E. coli*.

### **Methods**

To elucidate the transcriptional regulation of the T6SSs in UPEC strains, chromosomal and plasmid-based promoter-reporter gene fusions to core genes of both genomic islands have been constructed. The promoter activity has been tested in different *E. coli* K-12 deletion backgrounds as well as in various wild type *E. coli* strains.

### **Conclusions**

The screening using the promoter-reporter gene fusion demonstrated that the availability of nucleoid-associated proteins and the growth phase, i.e. the stationary phase, affect transcription of genes coding for core elements of T6SSs.

<sup>1</sup>LISM, IMM, Marseille, France

<sup>2</sup>AFMB, IFR48, Marseille, France

<sup>3</sup>Dept of Microbiologie, Wisconsin University, Madison, USA

**Background**

The bacterial type II secretion system (T2SS) is unique in its ability to promote the transport of large folded and sometimes multimeric proteins. In this secretion process, exoproteins are first translocated into the periplasm. The final release into the medium requires a multiprotein complex called the secreton.

**Objectives**

Although the 12 individual components of the secreton have been identified, its mode of action remains obscure.

**Methods**

We set up various dedicated *in vitro* and *in vivo* protein-protein interaction experiments to identify the *Pseudomonas aeruginosa* Xcp T2SS periplasmic interactome.

**Conclusions**

BIAcore experiments revealed that three Xcp components, XcpP, the secretin XcpQ, and the pseudopilus tip, directly and specifically interact with secreted exoproteins. Affinity chromatography co-purification indicated that the XcpY periplasmic domain interacts with the secreted substrate and a component of the pseudopilus tip XcpW. Interestingly, the periplasmic domain of another member of the Xcp inner membrane platform, XcpZ co-elutes with the XcpY/substrate and the XcpY/XcpW complexes during affinity chromatography. Finally the direct interaction between the secreted substrate and XcpY was confirmed by *in situ* photo-crosslinking. All together, our results allowed us to propose the most advanced integrative model of Xcp T2SS assembly and function.

<sup>1</sup>Medical Microbiology and Hygiene,

Interfaculty Institute of Microbiology and Infection Medicine Tübingen, Tübingen, Germany

<sup>2</sup>Proteome Center Tübingen, University of Tübingen, Tübingen, Germany

<sup>3</sup>Center for Plant Molecular Biology, University of Tübingen, Tübingen, Germany

### **Background**

Bacterial type III secretion systems are cell-envelope spanning effector protein-delivery machines employed by Gram negative pathogens and symbionts. The membrane-embedded core unit of these secretion systems is termed needle complex. It can be divided into a base that anchors the complex to the inner and outer membranes, a hollow filament composed of inner rod and needle subunits that serves as conduit for substrate proteins, and an export apparatus facilitating substrate translocation located at the center of the base.

### **Objectives**

While the low resolution structural analysis of the base has revealed the stoichiometry of this large ring-forming complex composed of three different proteins, the stoichiometries of the five hydrophobic export apparatus components and of the inner rod are largely unknown.

### **Methods**

We employed a mass-spectrometry based peptide-concatenated standard strategy to evaluate the stoichiometry of the entire needle complex.

### **Conclusions**

Using this strategy, we could validate the hitherto suggested stoichiometries of the base components and major export apparatus protein. We further propose a stoichiometry of 5:1:1:1 for the minor export apparatus components SpaP, SpaQ, and SpaR and for the switch-protein SpaS of the type III secretion system located on pathogenicity island 1 of *Salmonella* Typhimurium. The herein presented data also suggest that the inner rod is merely a rod but rather a disc because of the low stoichiometry observed.

Even though the complexity and hydrophobic character of the evaluated components allowed only the obtainment of approximate stoichiometries in this study, the gained results provide the first complete picture and a valuable framework for further investigations.

<sup>1</sup>Molecular Genetics, Weizmann Institute of Science, Rehovot, Israel

<sup>2</sup>Israel Structural Proteomics Center, Weizmann Institute of Science, Rehovot, Israel

**Background**

Toxin-antitoxin (TA) systems are highly abundant in bacteria and are typically composed of adjacently linked genes that encode both stable toxin and its unstable 'antidote'. TA systems were shown to have a diverse set of physiological roles that range from phage defense to bacterial persistence. We recently reported the discovery of six new types of TA systems (Sberro *et al.* Discovery of functional toxin/antitoxin systems in bacteria by shotgun cloning. Mol Cell. 2013 50(1):136-48).

**Objectives**

Here, we aimed in characterizing one of these newly discovered TA systems, Pmen TA. We propose that this toxin is involved in ADP-ribosylation, a post-transcriptional modification of crucial components within the bacterial cell. This mechanism is observed in a variety of bacterial exotoxins.

**Methods**

We use a combination of bioinformatics tools, molecular biology and biochemistry in order to attain initial characterization of this TA system after expressing it in *E.coli*.

**Conclusions**

The Pmen Toxin is predicted to have an NAD-binding domain that allows ADP-ribosylation activity. The anti-toxin is unstable and physically binds the toxin. It has an N-terminal domain, known to bind ADP-ribose, and its removal eliminates the rescue effect against the toxin. The conserved residues of the toxin resemble the core active site residues in other ADP-ribosylating toxins, such as Cholera toxin. Substitution of the most conserved active site residue leads to abolishment of toxicity. Possible common evolutionary origin between toxin-antitoxin systems and lethal exotoxins suggests that TA systems may be a genetic source for the emergence of pathogen-related toxins.

**Background**

Most prokaryotic genomes, including human pathogens, code for toxin-antitoxin (TA) systems, usually consisting of a toxin and its cognate antitoxin, which counteracts toxin activity. TA systems have been associated with a variety of biological functions, including general stress response, biofilm formation and pathogenicity. *Acinetobacter baumannii* is multidrug-resistant pathogen causing serious hospital-acquired infections worldwide. The internally encoded TA systems can be a useful tool in understanding and preventing the spread of multi-drug resistant *A. baumannii*.

**Objectives**

Recently, at least five functional *A. baumannii* TA systems (RelBE, HicAB, HigBA, SplTA, CheTA) were discovered. Their toxins were shown to inhibit translation in *Escherichia coli* cells. In order to characterize the *A. baumannii* toxins in more detail, we have investigated their cellular localization and ribosome-association.

**Methods**

Series of inducible *E. coli* expression vectors encoding *A. baumannii* TA components, fused with fluorescent proteins have been constructed. The functionality of fusion proteins in *E. coli* was confirmed using the kill-rescue assay. The ability of toxins to interact with ribosome was tested using ribosome fractionation, cellular localization was accessed by fluorescence microscopy.

**Conclusions**

Microscopy of *E. coli* where the fusion toxins, alone or with their cognate antitoxins, were expressed, has shown either polar or whole cell localization pattern. The analysis of fluorescence profiles of *E. coli* ribosomal fractions has demonstrated only RelE associated with ribosome, while association with the ribosome is unlikely for HicA, HigB and SpIT toxins of *A. baumannii*. The latter toxins might cleave RNA independently from ribosome, or inhibit translation by other mechanisms.

## **ALLELOPATHIC INTERACTIONS BETWEEN MICROCYSTIS AERUGINOSA 7806 AND DESMODESMUS SUBSPICATUS IN A CO-CULTURE EXPERIMENTAL MODEL**

A. Omid<sup>1</sup>, V. Contardo-Jara<sup>1</sup>, S. Kühn<sup>1</sup>, S. Pflugmacher<sup>1</sup>

<sup>1</sup>Ecotoxicological Impact Research and Ecotoxicology, Technische Universität Berlin, Berlin, Germany

### **Background**

Microcystins, produced primarily by cyanobacterium *Microcystis aeruginosa*, are the most commonly studied cyanotoxins (1). Most studies have focused only on the toxic effects of microcystins on humans and animals while their physiological or ecological roles have not been elucidated. Therefore, there is a considerable interest in understanding the importance of cyanotoxins in natural environments (2).

### **Objectives**

The aim of the present study was to clarify the ecological significance of microcystins in algal succession.

### **Methods**

*Desmodesmus subspicatus* was cultured in a medium together with dialysis tubing containing *M. aeruginosa* 7806. Cultures were incubated under  $30 \mu\text{Em}^{-2}\text{s}^{-1}$  continuous irradiation at 23°C for 4 weeks. Microcystin-LR was quantified using mass spectrophotometer and algal density was obtained by measuring the OD<sub>750</sub>.

### **Conclusions**

Microcystin-LR was determined in the media after two weeks but there was no change in *D. subspicatus* growth rate. After 4 weeks incubation, *D. subspicatus* growth decreased. Using co-cultivation method gave the opportunity to investigate the algal interactions at continuous toxin production. By continuing the growth of *M. aeruginosa*, toxin concentration increased and caused a decrease in *D. subspicatus* growth. Results provided evidences to suppose the role of toxin as an allelochemical in algal interactions.

<sup>2</sup>University of Graz, Medicine University of Graz, Graz, Austria

**Background**

*Campylobacter fetus* cause human infection and are important pathogens. Recent comparative genomics of *C. fetus* subspecies revealed *Fic* loci encoding Fido superfamily proteins, which may contribute to niche adaptation and pathogenicity.

**Objectives**

We analysed function of 4 *Fic* loci organized as toxin-antitoxin (TA) modules on the chromosome and ICE of *C. fetus* subsp. *Venerialis* 84-112.

**Methods**

The *C. fetus* proteins and mutant variants were expressed ectopically in *E. coli*, yeast and in transiently transfected HeLa cells. Prevalence of *fic* genes in 102 *C. fetus* isolates was surveyed with PCR

**Conclusions**

We show that *Fic* proteins are cytotoxic to human cells but not *S. cerevisiae*. The *fic* loci are organized as TA modules on the chromosome and ICE of *C. fetus* subsp. *venerialis* 84-112. Expression in *E. coli* validated the cytotoxic and neutralizing activities of the proteins, providing the first functional evidence for TA systems in *Campylobacter*. Reversal of *fic*-mediated filamentation and growth inhibition in *E. coli* also revealed antitoxin crossreactivity between loci. Key active site residues involved in adenylation by *Fic* proteins are conserved in *Fic1*, *Fic3* and *Fic4*, but degenerated in *Fic2*. We show the non-canonical *Fic2* disrupts assembly of *E. coli* ribosomes. *fic* genes are prevalent in *C. fetus* subsp. *venerialis* but not generally conserved among *Campylobacters*. Strikingly, homologous genes are found in some *Campylobacters* and unrelated pathogens adapted to the human and animal

urogenital tract. *C. fetus* *fic* genes thus appear to be important to adaptation and virulence in this niche.

## **TOXIN-ANTITOXIN SYSTEMS ON ANTIBIOTIC RESISTANCE PLASMIDS: JUST PLASMID MAINTENANCE?**

P. Bustamante<sup>1</sup>, J. Iredell<sup>1</sup>

<sup>1</sup>Centre for Infectious Diseases and Microbiology, Westmead Millenium Institute, Sydney, Australia

### **Background**

Toxin-Antitoxin (TA) systems are small genetic elements composed of a toxin gene and its cognate antitoxin. They were originally discovered as plasmid-borne loci that promote plasmid maintenance by killing daughter cells that have lost their TA encoding plasmid, a phenomenon known as post-segregational killing. Nowadays it is known that a great diversity of plasmids, including the antibiotic resistance (AbR) plasmids, encodes one or even more TA systems. The widespread dissemination of antibiotic resistance genes it is ascribed to the spread of bacterial plasmids encoding these genes and this successful dissemination it is attributed in part to TA systems and its participation in plasmid maintenance. However, there are some lights indicating that plasmidial TA systems could participate in functions other than plasmid maintenance.

### **Objectives**

Our main aim was to elucidate the diversity and function of TA systems encoded on AbR plasmids. Specifically to characterize a new putative TA system encoded on an IncX4 plasmid.

### **Methods**

By bioinformatic tools a novel putative TA system was identified in pJIE143, an IncX4 plasmid carrying *bla*<sub>CTX-M-15</sub> from an *Escherichia coli* ST131 isolate. We analyzed the effect of the expression of this system on *E. coli* growth and its participation on plasmid maintenance.

### **Conclusions**

pJIE143 encodes a novel TA system that appears to be related exclusively to IncX plasmids. The characteristics and putative functions of this novel TA system will be discussed in this work. These results reveal that AbR plasmids could contain an underappreciated diversity of TA systems, which could have functions further of plasmid maintenance.

<sup>5</sup>*Medical Parasitologyology, Tehran University of Medical Sciences, Tehran, Iran*

**Background**

The German cockroach, *Blattella germanica* (L.) has been recognized as a serious health problem throughout the world. Control failures due to insecticide resistance and chemical contamination of environment have led some researchers focus on the other alternative strategy controls. Microbial insecticides such as those containing entomopathogenic fungi could be of high significance. *Lecanicillium muscarium* and *Beauveria bassiana* grow naturally in soils throughout the world and act as a parasite on various arthropod species, causing white muscardine disease. Thus, these two species could be considered as entomopathogenic fungi.

**Objectives**

The current study conducted to evaluate the toxicity of *Beauveria bassiana* and *Lecanicillium muscarium* against German cockroach, *Blattella germanica*.

**Methods**

Conidial formulations of *L. muscarium* (PTCC 5184) and *B. bassiana* (PTCC5197) were prepared in aqueous suspensions with Tween 20. Bioassays were performed using two methods including submersion of cockroaches in conidial suspension and baiting. Data were analyzed by Probit program and LC50 and LC90 were estimated.

**Conclusions**

The obtained results indicated that both fungi species were toxic against German cockroach however; *Beauveria bassiana* was significantly 4.8 fold more toxic than *L. muscarium* against German cockroach using submersion method.

## **REGULATION OF TOXIN-ANTITOXIN SYSTEMS WITHIN THE SOS REGULON IN E. COLI**

M. Deghorain<sup>1</sup>, N. Mine<sup>1</sup>, L. Van Melderen<sup>1</sup>

<sup>1</sup>IBMM\_LGPB, Free University of Brussels (ULB), Gosselies, Belgium

### **Background**

TA systems (TAs) encode a stable toxic protein and its cognate unstable antitoxin that is either an antisense RNA (type I) or a protein (type II). Under steady-state conditions, both components are produced and cells are growing normally. Under conditions in which the antitoxin:toxin ratio is perturbed in favor of toxin, cell growth can be impaired. Therefore, maintaining an appropriate ratio is essential for viability. While negative autoregulation is observed for type II systems, few information is available for type I. Some of these TAs (*symER*, *tisAB-istR* and *dinQ-agr*) are part of the SOS regulon, as well as two type II TAs (*dinJ-yafQ* and *yafNO*).

### **Objectives**

Our objective is to investigate the transcriptional regulation of these TAs at the population and single cell levels under steady-state growth and SOS conditions.

### **Methods**

Approaches based on fluorescent reporters fused to TA promoters combined with flow cytometry and microscopy analysis are currently being developed.

### **Conclusions**

Our data confirmed that the *dinJ-yafQ* and *symE* promoters are activated during SOS response, although at different timing and levels. Interestingly, the *dinJ-yafQ* promoter is active both in wild-type and *dinJ-yafQ* mutant strains, indicating that SOS regulation prevails on autoregulation. Furthermore, heterogeneity in promoter activity was observed at the single cell level, suggesting that phenotypic heterogeneity might play a role in the SOS response. This will be further investigated.

## **EVOLUTIONARY RELATIONSHIPS BETWEEN TYPE II TOXIN-ANTITOXIN SYSTEMS AND POLYMORPHIC TOXIN SYSTEMS**

B. DUMONT<sup>1</sup>, F. PERIS-BONDIA<sup>1</sup>, L. VAN MELDEREN<sup>1</sup>, M.A.R.C. GARCIA-GARCERA<sup>2</sup>, E. ROCHA<sup>2</sup>

<sup>1</sup>Laboratory of Bacterial Genetics and Physiology, Free University of Brussels (ULB), Gosselies, Belgium

<sup>2</sup>Department of Genomes and Genetics, Pasteur institut, Paris, France

### **Background**

Type II toxin-antitoxin systems (TAs) are small bicistronic modules encoding a toxic protein and its cognate antitoxin protein. TAs are widespread in bacterial and archeal genomes.

### **Objectives**

Our hypothesis is that TAs might constitute a reservoir of toxic domains that are recruited by polymorphic toxin systems.

### **Methods**

Polymorphic toxin systems, such as CDI and Rhs, are composed of large conserved proteins containing variable carboxy-terminal (CdiA-CT or RhsA-CT) domains showing toxic activity and small immunity proteins. Genetic organization of these systems is analogous to that of TAs: a toxic gene or domain followed by an antitoxin or immunity gene. A bioinformatics approach is currently developed to evaluate whether CdiA-CT and RhsA-CT toxic domains are found in TAs. Domains are collected and HMM profiles are built. Bacterial genomes are scrutinized for the presence of these domains under TA organization. Functionality of these systems is tested in *E. coli*. Toxin activity and targets are then investigated.

### **Conclusions**

We identified and experimentally validated novel toxic domains that are found in TAs organization and in CDI and/or Rhs systems. Upon overexpression, toxins from TAs and CdiA-CT/RhsA-CT domains are toxic and antagonized by the expression of cognate antitoxin and/or immunity proteins. These domains were shown to inhibit translation. These data indicate that toxic domains are indeed shared by TAs and polymorphic toxin systems. Recruitment of toxic domains encoded by TAs by more

sophisticated systems might constitute a strong selective pressure on TAs and might explain why these small modules are evolutionary successful.

**NOVEL FAMILY OF TOXINS WITH ACETYLTRANSFERASE DOMAIN  
CONSTITUTE TYPE II TOXIN-ANTITOXIN SYSTEMS**

M. Jurenaite<sup>1</sup>, J. Sanz<sup>1</sup>, F. Peris-Bondia<sup>1</sup>, A. Garcia-Pino<sup>1</sup>, L. Van Melderen<sup>1</sup>

<sup>1</sup>IBMM, Free University of Brussels (ULB), Gosselies, Belgium

**Background**

Type II toxin-antitoxin (TA) systems are small genetic loci coding for a toxic protein and its antidote. Such systems are widespread in bacterial and archaeal genomes. These systems stabilize mobile genetic elements and may act as stress response elements. Toxins of type II TA systems are most commonly mRNAses, with the exception of gyrase inhibitors and several families that have more elaborate enzymatic functions. We have found novel class of toxins that possess acetyltransferase domain and constitute typical type II TA systems.

**Objectives**

To functionally describe TA modules of this novel family and explore mechanism of toxicity of acetyltransferase domain toxin.

**Methods**

TA systems from *Escherichia coli* and *Vibrio cholerae* have been functionally validated by killing/rescue assay. Activity of toxin has been tested by measuring rates of replication, transcription and translation, mRNAse activity by Northern blots analysis. Mutational analysis on acetyltransferase active site has been performed. TA complex has been purified and separated by affinity chromatography. Bioinformatics analysis has been performed to describe the prevalence and diversity of this novel family.

**Conclusions**

Small acetyltransferase domain proteins found in pair with RHH-domain antitoxins constitute functional TA pairs. When expressed together they form a heteromultimeric complex of 2 toxins and 2 antitoxins. When expressed alone toxins possessing acetyltransferase domain inhibit translation without degrading mRNAs and therefore exhibit novel toxicity mechanism. Mutations in the acetyltransferase active site abolish toxicity, strongly indicating that toxicity relies on target(s) acetylation. Detailed analysis of translation inhibition *in vitro* is currently under progress and should reveal the target(s) of the toxin.

**Toxin / antitoxin: activities and functions**

**CLAMP ALLOSTERY AND STEREOSELECTIVITY GOVERN THE MOLECULAR MECHANISM OF PROTEIN TRANSLOCATION THROUGH THE ANTHRAX TOXIN PROTECTIVE ANTIGEN CHANNEL**

B. Krantz<sup>1</sup>, D. Das<sup>1</sup>

<sup>1</sup>*Microbial Pathogenesis, University of Maryland Baltimore, Baltimore, USA*

**Background**

Anthrax toxin, composed of protective antigen (PA) and lethal (LF) and edema (EF) factors, is a model system for transmembrane protein translocation. The PA component self-assembles into a proton motive force (PMF)-driven channel, which translocates LF and EF into target cells. The channel contains multiple nonspecific polypeptide-clamp sites, which catalyze unfolding and translocation. It is unknown how clamps facilitate transport while avoiding tightly bound kinetic traps.

**Objectives**

As the  $\alpha$  clamp, specifically recognizes  $\alpha$  helix, we asked how the conformational dynamics of the translocating chain might avoid kinetic traps during translocation.

**Methods**

~50-residue peptides (based upon the sequence of LF) were synthesized with identical sequences but variable stereochemistries to control for side-chain chemistry while manipulating helical sense and backbone flexibility. Single-channel and ensemble planar lipid bilayer electrophysiology monitored peptide binding, dissociation, and translocation.

**Conclusions**

Cooperative binding and allosteric modulation of translocation were only observed with an isotactic peptide synthesized only with L-enantiomers ( $\alpha$ L). Cooperativity depended on acidic pH and the channel's  $\alpha$ -clamp and  $\phi$ -clamp sites. Incorporation of D-enantiomers disrupted cooperativity, allosteric control of translocation, and slowed the rate of translocation. The translocation of  $\alpha$ L occurs via a subsecond series of consecutive irreversible transitions and is unlike the translocation of a syndiotactic

peptide, synthesized with alternating L- and D-enantiomers ( $\alpha$ LD), which translocates 100-times slower (as slow as 776-residue LF). Therefore, to avoid kinetic traps, which may otherwise impede translocation, the channel's clamps operate allosterically through efficient, repeated, stereospecific contact along the length of the translocating peptide chain.

**TWO VAPBC-TYPE TOXIN-ANTITOXIN MODULES OF SINORHIZOBIUM MELILOTI INFLUENCE SYMBIOTIC EFFICIENCY AND NODULE SENESCENCE OF MEDICAGO SP.**

J. Lipuma<sup>1</sup>, A. Kiers<sup>1</sup>, R. Bonche<sup>1</sup>, I. Dusha<sup>2</sup>, N. Pauly<sup>1</sup>, I. Garcia<sup>1</sup>, L. Dupont<sup>1</sup>

<sup>1</sup>Symbiosis, Sophia Agrobiotech Institut, Sophia Antipolis, France

<sup>2</sup>Hungarian Academy of Sciences, Institute of Genetics Biological Research Center, Szeged, Hungary

**Background**

The symbiotic interaction between the bacterium *Sinorhizobium meliloti* and the legume *Medicago sp* results in the development of new root organs, the nodules, where the differentiated bacteria (the bacteroids) reduce atmospheric N<sub>2</sub> to ammonia. A few weeks after symbiosis establishment, nodules present a premature senescence.

**Objectives**

Since VapBC-type Toxin-Antitoxin (TA) systems of pathogenic bacteria is involved in the survival of the bacteria, we examined the role of *S. meliloti* VapBC modules in bacteroid viability and nodule senescence. The *vapBC* genes form an operon negatively regulated by the TA complex. Free toxin (VapC) has an RNase activity that is neutralized by the antitoxin (VapB).

**Methods**

We showed that, during the symbiotic interaction, a mutation in the *vapC5* toxin of the VapBC5 module, leads to a higher nitrogen-fixing activity, plant yield increase and a delayed nodule senescent phenotype. Thus, inactivation of this toxin improves symbiotic efficiency (Lipuma et al., 2014). We obtained an opposite phenotype with another mutant of toxin deletion (*vapC7*) : aberrant nodules, where nitrogen fixation is nearly abolished. Nodule ultrastructure analysis and flow cytometry demonstrated that bacteroid differentiation was followed by a rapid bacterial death leading to early senescence phenotype. These results demonstrate that this Toxin Antitoxin module is essential for bacteroid viability (in preparation).

**Conclusions**

We demonstrated the role of two Toxin Antitoxin systems in *S. meliloti* survival during *Medicago sp.* interaction. The two mutants analysed show different phenotypes. To a better understand the role of all VapBC systems; phylogenetic analyses were done to define the evolution origin of these genes.

**VAPC FROM THE LEPTOSPIRAL VAPBC TOXIN-ANTITOXIN MODULE  
DISPLAYS SPECIFIC RIBONUCLEASE ACTIVITY ON THE INITIATOR tRNA.  
VAPC HIGH PRESSURE REFOLDING AND IN SILICO STRUCTURAL 3D  
STUDIES.**

A.P.Y. Lopes<sup>1</sup>, E. Nakajima<sup>1</sup>, I.R. Mariano<sup>1</sup>, T.R. Fraga<sup>1</sup>, R.M. Chura-Chamb<sup>2</sup>,  
E. Cheng<sup>1</sup>, L. Morgant<sup>2</sup>, E.A.L. Martins<sup>1</sup>

<sup>1</sup>Centro de Biotecnologia, Instituto Butantan, São Paulo, Brazil

<sup>2</sup>Centro de Biotecnologia, Instituto de Pesquisas Energéticas e Nucleares,  
São Paulo, Brazil

**Background**

The most accepted hypothesis of the physiological function of the ubiquitous prokaryotic Toxin-Antitoxin (TA) operons is the reversible cessation of cellular growth under stress conditions. *vapBC* operons, present in *Leptospira interrogans*, are classified based on the presence of a ribonucleasic PIN domain in the VapC toxin. Their mechanisms of action remain mostly unknown. The expression of the leptospiral VapC in *E. coli* promotes a strong bacterial growth arrestment, making it difficult to obtain the recombinant protein.

**Objectives**

Produce soluble and active VapC in order to find its target and characterize its activity. Study and rank alternative 3D models of VapC.

**Methods**

*vapBC* locus, *vapB* and *vapC* of *L. interrogans* were cloned and expressed in *E. coli*. Proteins were purified by IMAC after refolding by pressurization (VapC). VapB and VapC interaction was tested by pull-down assay and affinity blotting. Ribonuclease activity was tested towards *E. coli* rRNA and tRNA<sup>fMet</sup>. Models of leptospiral VapC were generated and ranked using SWISS-MODEL.

**Conclusions**

VapC was refolded by high hydrostatic pressure, providing a new method to obtain the active toxin. VapB neutralizes the activity of VapC *in vivo* and *in vitro*. The 3D model of the leptospiral VapC closely matches the Shigella's VapC X-ray structure. In agreement, leptospiral VapC shows no activity towards *E. coli* rRNA and was found to cleave tRNA<sup>fMet</sup>. This finding suggests that the cleavage of the initiator tRNA may

represent a common mechanism to a larger group of bacteria and potentially configures a mechanism of post-transcriptional regulation leading to the inhibition of global translation.

## **THE IDENTIFICATION METHOD FOR THE SEQUENCE PATTERN AT THE CLEAVAGE SITES OF MAZF FAMILY ENDORIBONUCLEASES USING MASSIVE PARALLEL SEQUENCING**

T. Miyamoto<sup>1</sup>, Y. Sekiguchi<sup>2</sup>, S. Tsuneda<sup>1</sup>, N. Noda<sup>2</sup>

<sup>1</sup>*Department of life science and medical bioscience, Waseda University, Tokyo, Japan*

<sup>2</sup>*Biomedical Research Institute, National Institute of Advanced Industrial Science and Technology (AIST), Tsukuba, Japan*

### **Background**

MazF family toxins, representative endoribonucleases that cleave single-stranded RNA (ssRNA) in a sequence-specific fashion, are distributed among bacterial and archaeal lineages. Since their sequence pattern of cleavage sites is highly diverse, they are of importance not only in terms of prokaryotic physiologies, but biotechnological applications.

### **Objectives**

To elucidate physiological roles of MazF family toxins and/or to expand the biotechnological utilization of these endoribonucleases, we established a novel easy-to-use method to effectively determine the pattern of the sequences at their cleavage sites.

### **Methods**

The sequences cleaved by MazF family toxins were determined by a modified RNA-Seq protocol. To evaluate our method, MazF, an ACA specific endoribonuclease derived from *Escherichia coli*, was selected as a model target. Besides, the sequence digested by an uncharacterized MazF homologue from Proteobacteria was also identified using this method. The sequences recognized by these endoribonucleases were further analyzed by using Fluorescence Resonance Energy Transfer (FRET) based assays.

### **Conclusions**

The method developed in this study correctly inferred the sequence pattern at the cleavage sites of the model target, *E. coli* MazF, as ACA. Furthermore, the possible sequence pattern recognized by MazF homologue from Proteobacteria was consistent with the sequence confirmed by FRET based method, indicative that the present method is a useful and straightforward means to explore the potential sequence recognition pattern of these endoribonuclease. This method may be applicable to various toxins that catalyze ssRNA cleavage in a sequence-specific manner, facilitating subsequent physiological investigations and practical uses of these enzymes in the genetic engineering.

## FEMS-1372

### Toxin / antitoxin: activities and functions

#### IN VIVO CHARACTERIZATION OF A BACTERIAL KILLER TYPE IV SECRETION SYSTEM EFFECTOR/IMMUNITY PROTEIN PAIR

G.U. Oka<sup>1</sup>, D.P. Souza<sup>1</sup>, C.R. Guzzo<sup>2</sup>, S.C. Farah<sup>1</sup>

<sup>1</sup>Departamento de Bioquímica, Instituto de Química, São Paulo, Brazil

<sup>2</sup>Departamento de Microbiologia, Instituto de Ciências Biomédicas, São Paulo, Brazil

#### Background

Type IV secretion Systems (T4SS) are bacterial nanomachines that transfer proteins across the cell envelope and into target cells. We recently provided the first demonstration that the *Xanthomonas citri* (Xac) T4SS mediates the contact-dependent killing of other bacterial cells [1]. One *Xanthomonas* T4SS effector (X-Tfe) X-Tfe<sup>XAC2609</sup> has *in vitro* lysozyme-like lytic activity. This enzymatic activity is inhibited by the soluble domain of the putative *Xanthomonas* T4SS immunity protein (X-Tfi) X-Tfi<sup>XAC2610</sup>.

[1] D. P. Souza, G. U. Oka, et al., 'Bacterial Killing via a Type IV Secretion System,' *Nat. Commun.*, 2015.

#### Objectives

Here, we set out to investigate the *in vivo* function of X-Tfi<sup>XAC2610</sup>. Since X-Tfe<sup>XAC2609</sup> is predicted to act in the bacterial periplasm and X-Tfi<sup>XAC2610</sup> has a lipobox which directs it to the bacterial outer membrane, the hypothesis is that X-Tfi<sup>XAC2610</sup> acts as an immunity factor against the possibly detrimental autolytic effects of X-Tfe<sup>XAC2609</sup>.

#### Methods

Xac mutants strains carrying single gene deletions ( $\Delta$ X-Tfi<sup>XAC2610</sup>,  $\Delta$ X-Tfi<sup>XAC2609</sup> and  $\Delta$ T4SS) and double mutants ( $\Delta$ X-Tfi<sup>XAC2610</sup>- $\Delta$ T4SS and  $\Delta$ X-Tfi<sup>XAC2610</sup>- $\Delta$ X-Tfi<sup>XAC2609</sup>) were created. Colony phenotypes and cellular viabilities were compared for the above mutant and wild type Xac strains.

#### Conclusions

- 1) X-Tfi<sup>XAC2610</sup> provides immunity against the *in vivo* auto-lytic activity of X-Tfe<sup>XAC2609</sup>.
- 2) The *in vivo* autolytic activity of X-Tfe<sup>XAC2609</sup> does not depend on a functional T4SS.

3) X-Tfi<sup>XAC2610</sup> inhibitory activity is also independent of the Xac T4SS.

<sup>3</sup>Pathology and Pathogen Biology Royal Veterinary College,

University of London London United Kingdom., London, United Kingdom

<sup>4</sup>Department of Medical Microbiology and Parasitology Faculty of Medicine and Health Sciences, University Putra Malaysia, Putra, Malaysia

**Background**

Antibiotic-resistant bacteria have become a global concern and new strategies to control pathogenic bacteria are urgently needed. In theory, activation of the toxin or inhibition of the antitoxin within a bacterial toxin-antitoxin (TA) system could provide a potent new antibiotic therapy.

**Objectives**

we aimed to identify the location of TA systems, to evaluate the functionality of TA systems in clinical isolates of antibiotic-resistant *S. aureus*, to determine the functionality of TA system and to evaluate the antitoxin as an attractive antimicrobial target for the eradication of antibiotic-resistant *S. aureus*.

**Methods**

To evaluate potential TA loci as therapeutic targets, we screened the plasmid and chromosome sequences of 1000 clinical isolates of *S. aureus* for the presence of TA loci.

Plasmid transformation, ATPase assay, Turbidity and PNA assay were performed.

**Conclusions**

Plasmid-borne *mazEF* TA loci were present in all tested, antibiotic-resistant *S. aureus* strains in Iran and Malaysia. A subset of strains expressed the *mazE* and *mazF* transcripts, and ATPase and growth assays revealed that the *mazEF* TA loci were functional. In addition, the plasmid-borne copies were stable in the absence of antibiotic selection. To activate toxin expression, we targeted the *mazE* antitoxin mRNA using peptide nucleic acid (PNA) oligomers. The anti-*mazE* oligomers were bactericidal against drug-resistant *S. aureus* containing *mazEF* and did not inhibit strains lacking *mazEF*. Therefore, *mazEF* TA loci are widespread in drug-resistant strains of *S. aureus* and are plasmid-borne, and activation of toxin activity by silencing of the antitoxin gene provides a means to selectively kill drug-resistant strains.

## **CHARACTERIZATION OF TOXIN-ANTITOXIN SYSTEMS IN THE HUMAN PATHOGEN *STREPTOCOCCUS PYOGENES***

S. Hansen<sup>1</sup>, L. ZARATE BONILLA<sup>1</sup>, A. Le Rhun<sup>1</sup>, E. Charpentier<sup>1</sup>

<sup>1</sup>Regulation in Infection Biology -REGI, Helmholtz Centre for Infection Research, Braunschweig, Germany

### **Background**

The Gram-positive bacterium *Streptococcus pyogenes*, also known as group A *Streptococcus* (GAS), is an important human pathogen responsible for a wide spectrum of diseases such as pharyngitis, necrotizing fasciitis, and toxic shock syndrome. In addition to encoding multiple factors for adaptation and pathogenicity, GAS contains several predicted type II toxin-antitoxin (TA) loci. TA systems are widespread in bacterial pathogens and enable bacteria to adapt to rapidly changing environmental conditions, thereby contributing to the pathogenicity of the organisms.

### **Objectives**

To understand the role in physiology and virulence of these putative TAs in *S. pyogenes*, we aim to characterize hypothetical toxin-antitoxins (TAs) and unravel the molecular mechanisms involved in their regulation and mode of action.

### **Methods**

Operon architecture and expression of the predicted loci was analyzed by RT-PCR, RNA sequencing (RNA-seq), and reporter-fusions. Toxin and antitoxin activity and function was assessed by growth arrest assays, activity assays, Western blotting and microscopy.

### **Conclusions**

A series of transcriptional fusions was constructed that enabled the confirmation of TAs annotation. Three out of four predicted TAs cause growth arrest upon overexpression. We show that two of the predicted toxins cause a reduction in CFUs but not in optical density, which can be explained by a cell division defect. Expression of the cognate antitoxins was able to relieve the growth arrests. Understanding the roles of TAs will increase our knowledge on the regulation of bacterial pathogenicity, and may reveal key targets for potential novel antibacterial strategies.

## **EXPOSURE TO TICKS AND SEROPREVALENCE OF BORRELIA BURGDORFERI LIVING IN THE PROVINCE OF ERZINCAN, TURKEY**

A. Cikman<sup>1</sup>, M. Aydin<sup>1</sup>, B. Gulhan<sup>1</sup>, F. Karakecil<sup>2</sup>, L. Demirtas<sup>3</sup>

<sup>1</sup>Department of Medical Microbiology, Erzincan University School of Medicine, Erzincan, Turkey

<sup>2</sup>Department of Infectious Diseases, Erzincan University School of Medicine, Erzincan, Turkey

<sup>3</sup>Department of Internal Medicine, Erzincan University School of Medicine, Erzincan, Turkey

### **Background**

Lyme borreliosis is a zoonosis caused by *Borrelia burgdorferi* transmitted by ticks, especially Ixodes species.

### **Objectives**

The aim of this study was to determine the *Borrelia Burgdorferi* seroprevalence caused by ticks in the province of Erzincan, which has a high tick population due to its geographical position and climate conditions.

### **Methods**

368 people, who were live in rural area in the province of Erzincan located in the east of Turkey were included in the study. In all the acquired serum samples, the *B.burgdorferi* IgG antibodies were screened by using the ELISA method (SERION ELISA classic *Borrelia burgdorferi* IgG). The positive and doubtful results obtained were confirmed using the Western blot method (The VIRO-BLOT Anti-Borrelia IgG test).

### **Conclusions**

*B.burgdorferi* IgG antibodies were determined as positive (4.1%) in 15 of all cases and suspicious in 36 cases by using the ELISA method. *B.burgdorferi* IgG levels were examined by using the Western Blot method in totally 51 serum samples that were determined to be positive and doubtful according to the result of the SERION ELISA classic *Borrelia burgdorferi* IgG test. Evaluating all the results together; *B.burgdorferi* IgG positivity was found at the rate of 2.17 % in 8 of 368 cases. The story of tick contact was determined in 3 of cases that were determined to have positive *B.burgdorferi* IgG. *This study proved the presence of Borrelia Burgdorferi in the province of Erzincan. It is thought to offer the preventive health services for those in the risk group in order to minimize the tick exposure.*

#### **SEROPREVALENCE OF CRIMEAN-CONGO HEMORRHAGIC FEVER LIVING IN THE PROVINCE OF ERZINCAN, TURKEY**

A. Cikman<sup>1</sup>, M. Aydın<sup>1</sup>, B. Gulhan<sup>1</sup>, F. Karakecil<sup>2</sup>, A. Özcicek<sup>3</sup>, H. Akin<sup>2</sup>, M. Kara<sup>1</sup>

<sup>1</sup>*Department of Medical Microbiology, Erzincan University School of Medicine, Erzincan, Turkey*

<sup>2</sup>*Department of Infectious Diseases, Erzincan University School of Medicine, Erzincan, Turkey*

<sup>3</sup>*Department of Internal Medicine, Erzincan University School of Medicine, Erzincan, Turkey*

### **Background**

Crimean-Congo Haemorrhagic Fever (CCHF) is a zoonotic disease caused by a tick-borne CCHF of the genus *Nairovirus* of the family *Bunyaviridae*.

### **Objectives**

The aim of this study was to determine seroprevalence of the CCHF in animal breeders in the province of Erzincan, for which there has been no seroprevalence study despite being accepted as an endemic region in terms of the CCHF by the Ministry of Health.

### **Methods**

372 people, who were live in the province of Erzincan located in the east of Turkey were included in the study. In all the obtained 372 serum samples, the CCHF IgG antibodies were screened by using the ELISA method. The samples that were found to be CCHF IgG positive were examined with CCHF IgM. CCHF IgM-IgG ELISA kits were used in order to determine the antibody levels. IgM positive samples were processed for detection of viral RNA through RT-PCR.

### **Conclusions**

In 13.9% (52/372) of all samples included in the study, the CCHF IgG was determined as positive. This ratio was found respectively as follows; 16.7% (29/174) in people who had a tick contact/bite, 12.4% (18/145) in people who animal breeders and had no tick contact and 9.4% (5/53) in people who were not animal breeders in the city center and had no tick contact. Seven samples were found positive for IgM whereas viral RNA was detected in 1 samples. In the province of Erzincan where many CCHF-related death cases are reported every year, the CCHF IgG antibody level was found to be high as expected.

## **CUTANEOUS LEISHMANIASIS IN BADROOD- A HOT POINT OF LEISHMANIOSIS IN ISFAHAN,IRAN**

*M. Momen-Heravi<sup>1</sup>, H. Afzali<sup>1</sup>, H.A. Ahmad<sup>2</sup>, M. Saboori Kashani<sup>3</sup>*

*<sup>1</sup>infectious disease, Kashan University of Medical Sciences, Kashan, Iran*

*<sup>2</sup>Badrood hospital, Isfahan University of Medical Sciences, Badrood, Iran*

*<sup>3</sup>infectious disease, Kashan University of Medical Sciences, Kashan, Iran*

### **Background**

Cutaneous Leishmaniasis(CL) is a common endemic parasitological disease in Iran. This disease is always serious health problems in Esfahan province specially Badrood city and its prevalence has been doubled over the last decade

### **Objectives**

This study was designed to determine the epidemiology and clinical characteristics of CL in Badrood in 2013

### **Methods**

This descriptive cross sectional study was on all detected patients with cutaneous leishmaniasis in the city Badrood by active detection within one year in 2014. Patients were visited by physician and a questionnaire including information about demographic and characteristics of wounds were filled through interview and examination .Diagnosis was confirmed by revealing of leishman body in smear of wounds.

### **Conclusions**

we found 63 definitive case of CL .55.6% of patients were male. Age group 15-30 years had the highest rate (23.8%) among the patients. 66.7% of patients had history of stay in Agha Ali Abbas region. All wounds were rural form. Most patients with cutaneous leishmaniasis in Badrood had a wound with diameter less than 3 cm, secretion, painless, itch and extremities was the most common site for infection

Based on the findings of this study, cutaneous leishmaniasis in Badrood city is rural form and most patient are men and older than 15 year. there was complete or partial healing after treatment in the most patients.

Nnewi, Nigeria*

<sup>3</sup>*Department of Medical Laboratory Science, Ebonyi State University, Abakaliki,  
Nigeria*

### **Background**

Intestinal parasites are still major health challenges in tropical and sub-tropical areas. They are commonly found among people with low socio-economic status and in unhygienic environments. Children are usually more infected than adults due to easier fecal-oral transmission<sup>1</sup>. Children with parasitic infections are usually undernourished, weak and may have complications like diarrhoea, nutritional disorders and potentially lethal systemic disease.

### **Objectives**

To determine the prevalence of intestinal parasites among primary school children in Abakaliki metropolis.

### **Methods**

A total of 180 stool samples were aseptically collected and examined macroscopically by wet preparation (saline and iodine) and then microscopically by formal ether concentration techniques. The study was approved by Anambra State University Teaching Hospital Review Board.

### **Conclusions**

Out of the 180 stool samples examined, intestinal parasitic infection prevalence of 25.0% was recorded. Hookworm showed the highest of prevalence, followed by *Ascaris lumbricoides* and *Gardia lamblia*, while *Entaemoba histolytica* had the least prevalence. Prevalence in male was insignificantly higher than that of female ( $p>0.05$ ). The highest prevalence was recorded amongst age group 5-7 years. There was no significant difference in the rate of parasitic infection in relation to age ( $p>0.05$ ). Higher number of parasites was seen in the concentration technique as compared to other laboratory techniques (normal saline and Iodine method). Higher prevalence was seen among the children of farmers compared to other children. A well-structured control programme is needed to reduce mortality and morbidity from intestinal parasites and sustained commitment by the government and policy makers

are needed to improve the quality of life of these children.

## **EVALUATION OF HAIR SAMPLES AS TARGET TO DIRECT DETECTION OF LEISHMANIA SPP. IN LEPORIDAE**

T. García-Seco<sup>1</sup>, M.L. De la Cruz<sup>1</sup>, M.V. Ortega<sup>2</sup>, M. Pérez-Sancho<sup>3</sup>, I. Moreno<sup>4</sup>, M. Domínguez<sup>4</sup>, A. Prieto<sup>5</sup>, L. Domínguez<sup>1</sup>, N. García<sup>1</sup>

<sup>1</sup>Centro Visavet, Universidad Complutense de Madrid, Madrid, Spain

<sup>2</sup>Instituto Tecnológico La Marañosa,

Instituto Nacional De Técnica Aeroespacial (INTA), Madrid, Spain

<sup>3</sup>Campus CEI Moncloa-Centro Visavet, Universidad Complutense de Madrid, Madrid, Spain

<sup>4</sup>Área de Inmunología Unidad de Inmunología Microbiana e Inmunogenética, Instituto de Salud Carlos III, Majadahonda, Spain

<sup>5</sup>Madrid Salud, Ayuntamiento de Madrid, Madrid, Spain

### **Background**

Leishmaniasis is a parasitic zoonotic disease caused by *protozoa* of the genus *Leishmania*, responsible of high mortality in developing countries and considered one of the three major neglected parasitic diseases in developed countries. Wild reservoirs have a key role in certain epidemiological situations, i.e. *Leporidae* were significantly involved in the largest recorded European outbreak of leishmaniasis, in Madrid (Spain), still active. The possibility of monitoring *Leishmania* spp. using samples easy to obtain, with noninvasive techniques and stable for transport/storage is an essential key for surveillance programs in wild reservoirs. Previous studies have shown that hair samples are ideal for this purpose in dogs, mice and some wild species, but their suitability in wild *Leporidae* has not been studied before.

### **Objectives**

Assessment of hair as a target for direct detection of *Leishmania infantum* in wild *Leporidae*.

### **Methods**

Seventeen wild rabbits and nine hares from Madrid were included. Sera from all the animals were tested by immunofluorescence antibody test (IFAT). Moreover, hair, skin and spleen samples were subjected to DNA extraction and analyzed by real-time PCR for *Leishmania infantum*.

### **Conclusions**

All animals sampled (n=26) were positive to at least one of the three classic samples (serum, skin, spleen): 23 individuals (88.5%, 95%CI: 77.3%-100%) were positive in IFAT and 25 (96.2%, 95%CI: 88.2%-100%) were positive in skin/spleen RT-PCR.

A total of 22 hair samples (84.6%, 95% CI: 69.7%-99.8%) were positive. Despite the limited sample size, our results demonstrate that hair could be considered an adequate sample for direct diagnosis of *Leishmania infantum* infection in wild *Leporidae*.

**A NEW SPECIES OF CHOLEOEIMERIA (APICOMPLEXA: EIMERIIDAE)  
PARASITIC IN THE ROUGH-TAILED GECKO CYRTOPODION SCABRUM  
(SAURIA: GEKKONIDAE) IN EGYPT**

H. Abdel-Haleem<sup>1</sup>

<sup>1</sup>Zoology, Faculty of Science Beni-Suef University, beni-seweif, Egypt

**Background**

*Cyrtopodion* Fitzinger is a large genus of the Gekkonidae Gray (gecko) family with currently 28 described species. In contrast to the large diversity of this genus, only *Eimeria lineri* McAllister et al. 1988 has so far been described. In Egypt, the genus *Cyrtopodion* is represented only by *Cyrtopodion scabrum* Heyden 1827. Genus *Choleoeimeria* Paperna and Landsberg 1989 was proposed to incorporate eimeriid-like coccidia of elongate-ellipsoidal oocysts (L/W ratio 1.6–2.2), with sporocysts that lack a Stieda body and that develop in the epithelium of the gall bladder and bile duct of their hosts.

**Objectives**

The present work aims to establish the taxonomic status of an unknown *Choleoeimeria* from the gallbladder of the rough-tailed gecko *Cyrtopodion scabrum* using the characteristics of exogenous and endogenous stages of the parasite

**Methods**

A total of 15 rough-tailed geckoes, *Cyrtopodion scabrum* were collected and examined for coccidian infection. The presence of oocysts was determined by direct microscopic examination of bile contents. To study the endogenous stages, infected gallbladders were fixed in 10% neutral buffered formalin and embedded in paraffin. Sections were cut and stained with haematoxylin and eosin (H&E).

**Conclusions**

Based on the combination of the oocyst morphology, site and characters of the endogenous development; we assigned the present species to the genus *Choleoeimeria* and to which the name *Choleoeimeria scabrumi* n. sp. was suggested.

## **BACTERIAL CONTAMINATION OF TOYS AND PLAY AREAS IN RESTAURANTS AND SHOPPING MALLS IN RIYADH, SAUDI ARABIA**

S. Alwakeel<sup>1</sup>, D.A.N.A. Abo Alsamh<sup>2</sup>

<sup>1</sup>*Biology Department, University of Princess Nora Bent Abdul Rahman, RIYADH 11323, Saudi Arabia*

<sup>2</sup>*College of Medicine, King Saud Bin Abdulaziz University For Health Sciences, RIYADH 11323, Saudi Arabia*

### **Background**

This study was conducted to determine the load of pathogenic bacterial contamination and explore the prevalence of pathogenic bacterial species in play areas of fast food restaurants and shopping malls in Riyadh, Saudi Arabia. This novel study aims to pilot other studies in the area to explore bacterial contamination for purposes preventing pediatric disease

### **Objectives**

The study seeks to identify and determine the load and antibiotic sensitivity of bacterial organisms in the play areas present in fast food restaurants and shopping malls in Riyadh, Saudi Arabia.

### **Methods**

The sample included three fast food restaurants' play pits and two shopping mall play areas in Riyadh, Saudi Arabia during the month of March in 2012. Nineteen samples were isolated using sterile swabs from surfaces of balls in ball pits and different arcade games. Samples were inoculated onto blood agar and MacConkey agar and were incubated 24 hours at 37° C. Bacterial species were identified and tested for their antibiotic sensitivity. Bacteria isolated from a total of 19 samples included *Klebsiella pneumoniae*, *Staphylococcus spp.*, Diphtheroids, *Pantoea agglomerans*, *Enterococci spp.*, *Streptococci viridans* and two fungal growths that included *Aspergillus spp.* and *Penicillium spp.*

### **Conclusions**

The results of this study confirm that toys in play areas and arcades could serve as media for the transmission of pathogenic microorganisms and fungal elements that pose a potential health risk for children.

**EFFECTS OF ORAL ADMINISTRATION OF THE BUTYRIVIBRIO GROUP BACTERIUM ON THE INFLAMMATORY DRY SKIN CONDITION IN CHRONIC IRRITANT CONTACT DERMATITIS**

N. Asanuma<sup>1</sup>

<sup>1</sup>Life Science, Meiji University, Kawasaki, Japan

**Background**

The genus *Butyrivibrio* is one of the predominant residents in the rumen, and also inhibits the intestine of monogastric animals. We previously reported that oral administration of *B. fibrisolvens* to mice alleviated experimental enterocolitis and suppressed the formation of colorectal aberrant crypt foci. Although the preventive mechanisms of this bacterium have been still unknown, it might have the potential to improve immune responses. Thus, some strains of this bacterial group might be used for improving the dysfunction in inflammatory skin diseases such as irritant contact dermatitis (ICD).

**Objectives**

The newly strain of *Butyrivibrio* group to improve the skin barrier function was isolated and its effect on inflammatory dry skin was examined.

**Methods**

Several strains of the *Butyrivibrio* group bacteria were isolated from the goat rumen and confirmed by reading the nearly full-length 16S rRNA gene sequences. Some strains were examined as the candidates for probiotic bacteria that recover the skin barrier function. Chronic ICD was induced to mice with oxazolone at the ears by repeated application. The isolated strains were administrated as the freeze-dried cells. The beneficial effects on cutaneous inflammation were evaluated by the dermatitis severity score, lymph node weight, histological analysis, and mRNA expression of IL-1 $\beta$  and IL-6 in the lesional ear.

**Conclusions**

When the isolated strain was administrated, the development of skin roughness or exfoliation was alleviated and mRNA expression of the pro-inflammatory cytokines was suppressed. In conclusion, this newly isolated *Butyrivibrio* strain might be used as a probiotics for the restoring the skin barrier function.

**EMULSION OF THE AMAZON FOR DENTAL CAVITY CLEANING: PHYSICO-CHEMICAL QUALITY CONTROL AND EVALUATION OF ANTIBACTERIAL ACTIVITY**

M. Bandeira<sup>1</sup>, P.S. Milerio<sup>1</sup>, F.C. Sampaio<sup>2</sup>, C.N. Coelho<sup>1</sup>, C. Toda<sup>1</sup>,  
M.C. Vasconcelos<sup>3</sup>, L.G. Moura<sup>3</sup>, L.R. Machado<sup>3</sup>, N.C.O. Conde<sup>1</sup>

<sup>1</sup>Dental School, Amazonas Federal University, Manaus, Brazil

<sup>2</sup>Dental School, Paraíba Federal University, João Pessoa, Brazil

<sup>3</sup>Pharmacy School, Amazonas Federal University, Manaus, Brazil

**Background**

The dental field has been developed with the purpose of seeking new bioactive principles for the formulation of drugs with different applicability.

**Objectives**

Analyze the stability of an emulsion of copaiba oil (*Copaifera multijuga* – CM) for dental cavity cleaning. In this emulsion was performed physico-chemical tests and antibacterial test in different environments and periods.

### Methods

The results of the pH and density determination were analyzed by ANOVA and Bonferroni's test ( $p < 0,05$ ). For other tests were given descriptive analysis. In the centrifugation, there was no phase separation at time 0, in 3 months (freezer, refrigerator and air conditioning) and in 6 months (in the freezer and refrigerator) ; in the pH, the incubator, the room temperature protected from light, the room temperature and the air conditioning had statistically significant difference from the control group (time 0); at density, the incubator had the lowest density values; in microbiological evaluation, there was no bacterial growth; for the evaluation of organoleptic characters, there was only change in color of the emulsion in 3 months (incubator) and 6 months ( incubator , room temperature protected from light and room temperature). The CM showed bacteriostatic and bactericidal activity, respectively, in concentrations of 13.33 $\mu$ L/ml and 15  $\mu$ L/ml for *S. mutans*; 20  $\mu$ L/ml and 23.33  $\mu$ L/mL for *S. salivarius* and 13.33  $\mu$ L/ml, 15  $\mu$ L/ml for *L. paracasei*; 8.33 $\mu$ L/ml and 8.33 $\mu$ L/ml for *S. oralis*.

### Conclusions

The authors concluded that the CM demonstrated bactericidal activity; presented conditions of stability and quality without contaminants, the best storage environment is refrigerator.

**A CASE OF CHRONIC OTITIS MEDIA DUE TO ACHROMOBACTER  
XYLOSOXIDANS IN AN IMMUNOCOMPETENT PATIENT**

T. Hosbul<sup>1</sup>, C. Durmus<sup>2</sup>, B. Bektore<sup>3</sup>, M.B. Selek<sup>3</sup>, O. Baylan<sup>3</sup>, M. Ozyurt<sup>3</sup>

<sup>1</sup>Medical Microbiology, Golcuk Military Hospital, Izmit, Turkey

<sup>2</sup>Otorhinolaryngology, Golcuk Military Hospital, Izmit, Turkey

<sup>3</sup>Medical Microbiology,

Gulhane Military Medical Academy Haydarpasa Training Hospital, Istanbul, Turkey

**Background**

*Achromobacter xylosoxidans* is an aerobic, oxidase positive, non-fermentative, gram-negative bacillus and often misidentified as *Pseudomonas aeruginosa* by its oxidase positive feature. It may cause serious nosocomial and community-acquired infections especially in patients with immune deficiency.

**Objectives**

We present a case of chronic otitis media due to *A.xylosoxidans* which is rarely isolated from clinical materials in routine microbiology laboratory practice. In this report we emphasize clinical impact of *A.xylosoxidans* and its antimicrobial resistance profile.

**Methods**

A 20-year-old immunocompetent man was admitted to otorhinolaryngology service of our hospital with the complaints of left ear pain, difficulty in hearing, left ear discharge beginning from nearly three months his admission. His history revealed unsuccessful treatment attempts with various oral antimicrobials with the diagnosis of otitis media. Tympanic membrane perforation and mucopurulent yellow discharge was observed. He had no systemic symptoms. Microscopic examination of the Gram stained smear revealed PMNL and gram negative bacilli. *A.xylosoxidans* was isolated from discharge. Identification was performed by VITEK 2 automated system. Antimicrobial susceptibility was detected by disc diffusion method according to CLSI criteria for *Pseudomonas* spp. It was resistant to penicillins, most of the beta lactamases, fluoroquinolones, aminoglycosides and susceptible to piperacillin-tazobactam and imipenem.

## Conclusions

*A.xylosoxidans* strains are often multidrug resistant. Empirical antibiotic therapy with piperacillin-tazobactam or a carbapenem is a reasonable choice until the results of susceptibility tests are available. It should be kept in mind that even an opportunistic and generally nosocomial pathogen like *A.xylosoxidans* can cause community-acquired infection like otitis media in a immunocompetent host.

## EFFECT OF TRANS-CHALCONE ON TRANSCRIPTION OF GENES RELATED TO CELL WALL AND FATTY ACID SYNTHESIS IN THE DERMATOPHYTE TRICHOPHYTON RUBRUM

T.A. Bitencourt<sup>1</sup>, T.T. Komoto<sup>1</sup>, M. Marins<sup>1</sup>, A.L. Fachin<sup>1</sup>

<sup>1</sup>Unidade de Biotecnologia, Unaerp, Ribeirão Preto, Brazil

### Background

*Trichophyton rubrum* is the main causative agent of dermatophytosis worldwide. The infections caused by this dermatophyte are not lethal but are uncomfortable and difficult to treat. Moreover, invasive infections are rising due to modern medical interventions and immunosuppressive diseases. The development of fungal resistance limits the arsenal of antifungal drugs, which has a narrow spectrum of activity and often presents toxicity to the host. Therefore, novel drugs with more specific and effective mechanisms of action against dermatophytes are urgently needed. Chalcones drew attention by numerous pharmacological applications, including antifungal activity.

### Objectives

The aim of this study was to evaluate the modulation of genes involved in cell wall and fatty acid synthesis of *T. rubrum* after the exposure to *trans*-chalcone.

### Methods

The modulation of fatty acid synthesis genes (FAS 1p and FAS 2p subunits, acetyl-CoA carboxylase 2p subunit) and genes of cell wall synthesis (beta-1,3-glucanosyltransferase and glycosylphosphatidylinositol anchored protein) was checked by qPCR after the exposure to MIC (7.8 µg/mL) and ¼ MIC (1.95 µg/mL) of *trans*-chalcone, respectively, for 16h for fatty acid genes and 7h for cell wall genes.

### Conclusions

*Trans*-chalcone promoted a down-regulation of genes of fatty acid synthesis whereas cell wall genes were up-regulated. These results suggest that *trans*-chalcone may act on different fungal specific targets, which could be considered an advantage for an antifungal compound.

## REP-PCR GENOMIC FINGERPRINTING AND NEW INSIGHTS INTO PHYSIOLOGICAL TRAITS OF ACIDIPLASMA STRAINS

*A. Bulaev*<sup>1</sup>, *M. Sukhacheva*<sup>2</sup>, *B. Kuznetsov*<sup>2</sup>

<sup>1</sup>Laboratory of Chemolithotrophic Microorganisms,

Winogradsky Institute of Microbiology RAS Moscow Russia, Moscow, Russia

<sup>2</sup>Laboratory of Molecular Diagnostics,

Bioengineering Center Russian Academy of Sciences, Moscow, Russia

### Background

*Acidiplasma* is the genus of acidophilic, ferrous iron-oxidizing, heterotrophic, cell wall-lacking, moderately thermophilic microorganisms belonging to the family *Ferroplasmaceae*. All representatives of the genus have high similarity of 16S rRNA gene (99-100%). The genus includes two species (*A. aeolicum* and *A. cupricumulans*) separated by DNA–DNA hybridization (DDH) values. However complexity of DDH suggests to necessity of application of alternative tools for distinguishing representatives within the genus. Also information about physiological traits of the genus may be incomplete. In our previous study the new physiological trait (ability to oxidize elemental sulfur) was shown by the example of strain *Acidiplasma* MBA-1.

### Objectives

The aims of this study were to apply rep-PCR fingerprinting technique for distinguishing *Acidiplasma* representatives and to investigate sulfur oxidation by the strains *A. aeolicum* V<sup>T</sup>, *A. cupricumulans* BH2<sup>T</sup>, *Acidiplasma* MBA-1, *Ferroplasma acidiphilum* Y<sup>T</sup>.

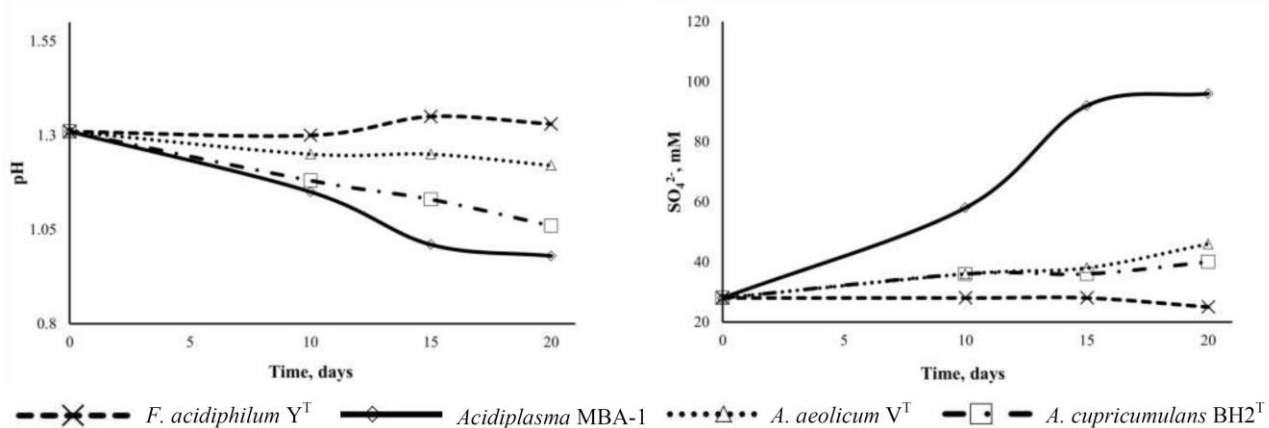

Figure 1. Oxidation of sulfur by *Acidiplasma* strains and *Ferroplasma acidiphilum* Y<sup>T</sup>

## Methods

The genomic fingerprints were obtained using BOXA1, BOXS1, ERIC and REP primers. Oxidation of sulfur was estimated by pH decreasing and increasing of sulfates-ions concentrations.

## Conclusions

Sulfur was oxidized by all *Acidiplasma* strains, but not by *F. acidiphilum* Y<sup>T</sup> (Fig. 1). It suggests sulfur oxidation can be widely distributed among *Acidiplasma* representatives, but not among *Ferroplasma* representatives. Each of *Acidiplasma* strains possess its unique genomic fingerprint (Fig. 2), it suggests genomic fingerprinting could be rapid, highly discriminatory screening techniques for *Acidiplasma* representatives. The work was supported by the Russian Foundation for Basic Research, project no. 14-04-31210 mol\_a and Core Research Facility 'Bioengineering' equipment.

## **TREATMENT AGAINST THE MICROBIAL ACTIVITY WITH CINNAMON ESSENTIAL OIL IN ARTISTIC WORKS AND PACKAGING**

M. Calvo<sup>1</sup>, E.L. AROSEMENA<sup>1</sup>, S. NOGUER<sup>2</sup>

<sup>1</sup>SANITAT I ANATOMIA ANIMALS, Autonomous University of Barcelona, Bellaterra Barcelona, Spain

<sup>2</sup>CONSERVACIÓN, MACBA, Barcelona, Spain

### **Background**

The artwork and the packaging system used in all transfers and storage is a good substrate for the growth of microorganisms that can produce irreversible changes, as destruction or alteration of substrates on which microorganisms can multiply and that as a result of secondary metabolism can accumulate among them the indelible pigment

### **Objectives**

The aim of this study is to provide a preventive solution to the development of microorganisms without risk to the integrity of the artwork.

### **Methods**

We proceeded through sterile swabs to collection of samples from artwork and packaging deposited in the MACBA. Samples were plated on TSA to determine the presence of bacteria and AS with antibiotic to determine fungi.

All artwork and packaging were submit an aspiration synthetic pallet and vacuum equipped with a HEPA filter.

Then, we applied by spraying a mixture of alcohol: water: cinnamon and elsewhere , to compare the results for the traditionally used mixture formed alcohol: water.

After a month of the application of the products we collected samples from all the treated areas in order to evaluate the efficacy of treatments. In order to assess the effect of treatment in cases of contamination, proceeded experimentally inoculated packaging materials and pieces of artwork who underwent both treatments indicated and to expose the action of an environment contaminated items artistic and packaging that did not have initially any pollution.

### **Conclusions**

The results indicates that the mixture comprising cinnamon oil has a strong antimicrobial effect and avoid contamination of sensitive material in contact with elements altered by microorganisms.

## **THE EFFICACY OF PRtA TO PREVENT STREPTOCOCCUS PNEUMONIAE INFECTION**

*J. Chen*<sup>1</sup>, *S. Tseng*<sup>2</sup>, *Y. Chuang*<sup>1</sup>

<sup>1</sup>*Microbiology and Immunology, National Defense Medical Center, Taipei, Taiwan*

<sup>2</sup>*Research Center of Bacterial Pathogenesis, Chang Gung University, Taoyuan, Taiwan*

### **Background**

*Streptococcus pneumoniae* is a respiratory pathogen contributing to severe lung infection and/or bacteremic complications. Worldwide efforts were made to develop a conserved protein vaccine against *S. pneumoniae* and to provide a maximal and memory protection.

### **Objectives**

The pneumococcal surface protein, PrtA, was identified by convalescent patient serum screening on a pneumococcal genomic expression library. The *prtA* gene is prevalent and conserved among *S. pneumoniae* strains; however, there was no report describing its protective efficacy.

### **Methods**

Since IL-17A elicitation can improve the clearance of pneumococcal colonization, we combined a recombinant PrtA fragment (aa 144-1041) with curdlan, a strong inducer of IL-17A, to vaccinate three-wk old CD1 mice intranasally once a week for three weeks. It showed an elevated PrtA-specific Ab titer in mucosa and increased IL-17A production by splenocytes compared with sham group. Finally, the PrtA vaccination can successfully reduce *S. pneumoniae* D39 colonization in lung within 24 hr but failed to reduce the mortality after 12 days of infection. All of the experiments were approved by the Institutional Animal Care and Use Committee of the National Defense Medical Center Laboratory Animal Center. The animal experiments were performed in strict accordance with the Taiwan regulations of the Animal Protection Act and the course on Animal Care and Use in Research and Education from the American Association for Laboratory Animal Science.

### **Conclusions**

Combined with PrtA fragment and curdlan adjuvant can enhance PrtA-specific humoral and cellular immunity; however, the vaccination was not sufficient to protect against *S. pneumoniae* infection.

## **ANTI-TOXOPLASMA ACTIVITIES OF METHANOLIC EXTRACT FROM ZEA MAYS AND ERYNGIUM CAUCASICUM**

A. Daryani<sup>1</sup>, M.A. Ebrahimzadeh<sup>2</sup>, M. Sharif<sup>1</sup>, E. Ahmadpour<sup>1</sup>, S. Edalatian<sup>3</sup>, S.H. Sarvi<sup>1</sup>

<sup>1</sup>Toxoplasmosis Research Center, Mazandaran University of Medical Sciences, Sari, Iran

<sup>2</sup>Pharmaceutical Sciences Research Center School of Pharmacy, Mazandaran University of Medical Sciences, Sari, Iran

<sup>3</sup>Microbiology, Amol Azad University, Amol, Iran

### **Background**

*Toxoplasma gondii* is an obligatory intracellular parasite that infects a wide range of warm-blooded animals and humans.

### **Objectives**

Considering the severity of toxoplasmosis, side effects of current treatments, and the contribution of the ethnopharmacological knowledge for the treatment of parasitic infections, the aim of the present study was to investigate the efficacy of methanolic extracts of *Zea mays* and *Eryngium caucasicum* against tachyzoite of *T. gondii*.

### **Methods**

Four concentrations (5, 10, 25 and 50 mg ml<sup>-1</sup>) of extracts were incubated with infected macrophages for 30, 60, 120 and 180 min and then the viability of the tachyzoites were evaluated by trypan blue staining.

### **Conclusions**

Concentrations of 10 and 25 mg ml<sup>-1</sup> of *Z. mays* after 180 minutes, and also concentration 50 mg ml<sup>-1</sup> after 120 minutes killed 100% of the tachyzoites. Also high anti-*Toxoplasma* activity was seen using *E. caucasicum* extract. The anti-*Toxoplasma* effects of the methanolic extracts from *Z. mays* and *E. caucasicum* did not show any significant difference in comparison with pyrimethamine (positive control). Findings of this research indicate that these extracts have acceptable anti-*Toxoplasma* efficacies *in vitro* and it can be used as candidate extracts for further research on treatment of toxoplasmosis *in vivo*.

**THE INHIBITORY EFFECT OF CROMOLYN SODIUM AND KETOTIFEN ON  
TOXOPLASMA GONDII ENTRANCE INTO HOST CELLS IN VITRO AND IN VIVO**

A. Daryani<sup>1</sup>, F. Rezaei<sup>1</sup>, M.A. Ebrahimzadeh<sup>2</sup>, M. Sharif<sup>1</sup>, S.H. Sarvi<sup>1</sup>, E. Ahmadpour<sup>1</sup>

<sup>1</sup>Toxoplasmosis Research Center, Mazandaran University of Medical Sciences, Sari,  
Iran

<sup>2</sup>Pharmaceutical Sciences Research Center,  
Mazandaran University of Medical Sciences, Sari, Iran

**Background**

*Toxoplasma gondii* is a protozoan with worldwide distribution and in spite of increasing information about its biology, treatment of toxoplasmosis is restricted to a few drugs and unfortunately using of each of drugs is associated with significant side effects in patients.

**Objectives**

This study was designed to evaluate the efficacy of cromolyn sodium and ketotifen as alternative drugs for the treatment of toxoplasmosis.

**Methods**

In vitro; in case group, concentrations of 1, 5, 10 and 15 lg/ml of ketotifen and cromolyn sodium were added to RPMI medium containing peritoneal macrophages. After 1 h incubation and adding tachyzoites to medium, efficacy rate of these drugs in entrance inhibition of *Toxoplasma* tachyzoites into macrophages were evaluated after 30 and 60 min. In vivo; case groups received ketotifen and cromolyn sodium with different concentrations at various times. Control groups received none of drugs.

**Conclusions**

We found that in vitro; after 60 min the best efficacy of these drugs in inhibition of cell entrance of *Toxoplasma* was observed at 15 lg/ml ( $78.9 \pm 1.70$  and  $91.97 \pm 0.37$  %, respectively) ( $P \leq 0.05$ ). In vivo; after 60 min ketotifen at 2 mg/kg in 3 h before tachyzoite injection ( $69.83 \pm 2.25$  %), and cromolyn sodium, at 10 mg/kg in 6 h before tachyzoite injection ( $80.47 \pm 2/49$  %) had the

best effect on inhibition of *Toxoplasma* entry into the cells ( $P \leq 0.05$ ). Our findings show that ketotifen and cromolyn sodium are suitable drugs for entrance inhibition of tachyzoites into nucleated cells in vitro and in vivo.

**THE NAGOYA PROTOCOL: REVOLUTION OR EVOLUTION? ACCESS AND STUDY OF MICROBIAL DIVERSITY IS SUBJECT TO NEW REGULATION**

P. DESMETH<sup>1</sup>

<sup>1</sup>*President, World Federation for Culture Collections, Brussels, Belgium*

**Background**

The Nagoya Protocol<sup>[i]</sup> (NP) under the Convention on Biological Diversity (CBD) has entered into force on 12 October 2014. The NP covers the use of biological diversity in Research and Development. If not correctly translated by lawmakers or inefficiently apprehended by microbiologists it could heavily impact the activities of Culture Collections (CC) and their partners<sup>[ii]</sup>. The European lawmakers have already translated the NP into European Regulation<sup>[iii]</sup>.

[i] Nagoya Protocol on Access to Genetic Resources and the Fair and Equitable Sharing of Benefits Arising from their Utilization to the Convention on Biological Diversity. (<http://www.cbd.int/abs/> )

[ii] Fidler, D.P. (2008). Influenza Virus Samples, International Law and Global Health Diplomacy. *Emerg. Infect Dis* Jan 2008 14(1): 88-94.

[iii] Regulation (EU) No 511/2014 of the European Parliament and of the Council of 16 April 2014 on compliance measures for users from the Nagoya Protocol on Access to Genetic Resources and the Fair and Equitable Sharing of Benefits Arising from their Utilization <http://eur-lex.europa.eu/legal-content/EN/TXT/HTML/?uri=CELEX:32014R0511&from=EN>

**Objectives**

The challenge is to organize efficiently the access and the conveyance of transfer and utilization of the microorganisms at affordable cost.

**Methods**

CCs have anticipated these legal developments and have presented solutions during the 1st NP's Meeting of the Parties.

## **Conclusions**

CCs propose TRUST<sup>[i]</sup>, a system to help microbiologists dealing with this new set of rules on access and utilization of biological diversity, including micro-organisms.

[i] Implementing the Nagoya Protocol in microbiology - Gaining trust, building TRUST.

## **TREHALOSE METABOLISM IN SACCHAROMYCES CEREVISIAE DURING HEAT STRESS**

E. ELEUTHERIO<sup>1</sup>, R. MAGALHÃES<sup>1</sup>

<sup>1</sup>*Institute of Chemistry, Federal University of Rio de Janeiro, Rio de Janeiro, Brazil*

### **Background**

*Saccharomyces cerevisiae* trehalose synthesis complex is composed by Tps1 and Tps2 and two regulatory subunits, Tsl1 and Tps3. To protect membranes trehalose must be present on both sides of the bilayer.

### **Objectives**

Our goal was to elucidate the protective mechanism of trehalose.

### **Methods**

The absence of Tsl1 abolished the increase in Tps1 activity and accumulation of trehalose in response to a 40°C treatment, whereas deficiency of Tps3 only reduced Tps1 activity and trehalose. In extracts of heat stressed cells, Tps1 was inhibited by trehalose-6-phosphate and by cAMP. In contrast, cAMP-dependent phosphorylation did not inhibit Tps1 in *tps3* cells, which accumulated a higher proportion of trehalose-6-phosphate after heating. Agt1 deficiency led to a reduced tolerance to heat shock, without interfering in trehalose accumulation, probably because the outside of the lipid bilayer was unprotected. *ath1* cells still showed a high trehalose levels when they were shifted back from 40 to 28°C, as well as, increased tolerance to a subsequent heat stress.

### **Conclusions**

We conclude that Agt1 plays a crucial role in transporting endogenous trehalose to the outer side of the plasma membrane when yeasts face adverse conditions. With the end of the stress, the intracellular trehalose pool would be hydrolyzed by Nth1 whereas the external molecules would be hydrolysed by Ath1. To stop readily trehalose synthesis during stress recovery, Tps3 would be phosphorylated by cAMP-dependent protein kinase, decreasing Tps2 activity and, consequently, increasing trehalose-6-phosphate levels which, in turn, would inhibit Tps1. We believe that these concepts are of great importance for medical and biotechnological applications.

## **INVESTIGATION OF ROSMARINUS OFFICINALIS L EXTRACT ON THE BACTERIA CAUSES GENITAL INFECTION**

M. esmaeili<sup>1</sup>, G. esmaeili<sup>1</sup>, S. mashhad<sup>2</sup>

<sup>1</sup>department of microbiology, shahid beheshti university of medical sciences, Tehran, Iran

<sup>2</sup>School of Pharmacy, Azad University of Pharmacy Tehran Iran, Tehran, Iran

### **Background**

Some microbial causes in creating vaginitis are *streptococcus group B* and *Gardnerella vaginalis* which result in irrecoverable harms and increasing fatality, and providing infection in pregnancy period and transfer to the baby.

### **Objectives**

the antibacterial effects some plants like Rosemary (*Rosmarinus officinalis*) on vaginitis we can identify these kinds of plants and then give them to the people in the form of plant drugs. This research is an investigation of Rosemary and its antibacterial effect on the bacteria and also comparing this effect with common antibacterial.

### **Methods**

This study of 96 women who suffered from this disease, all samples confirms with phenotyping method. The Disk diffusion method was used for comparing the effect of antibacterial total extract with common antibiotics.

### **Conclusions**

The MIC result for each strain showed respectively; *streptococcus* 1/64, *Listeria* 1/128, *Candida Albicans* 1/2, *staph aureus* 1/128, *Gardenerella vaginalis* 1/64. In the disk diffusion method, the results were in this form which *streptococcus group B*, *staph aureus* and *Gradenerella vaginalis* were more sensitive than antibiotic disk in comparing with extract, While *Listeria monocytogenes* was more sensitive than antibiotic disk to the extract.

### **Background**

Lignin is one of the major components of plant cell wall and has significant impact on animal digestion of plants. It is known that Phanerochaete secretes a series of extracellular oxidases, which are encoded in multiple genes, to degrade lignin. However, Phanerochaete needs more stringent conditions to ferment. For animal husbandry application, it is challenge in genetic engineering to transfer all required oxidase genes from Phanerochaete into other strains that can ferment easily. Therefore, we chemically fuse protoplasts between *Pleurotus ostreatus*, a Phanerochaete strain, and *Saccharomyces cerevisiae*. To gain strains with the excellent characteristics of both *Pleurotus ostreatus* and *Saccharomyces cerevisiae*.

### **Objectives**

We chemically fuse protoplasts between *Pleurotus ostreatus*, a Phanerochaete strain, and *Saccharomyces cerevisiae* to gain strains with the excellent characteristics of both *Pleurotus ostreatus* and *Saccharomyces cerevisiae*.

### **Methods**

At first, the enzymatic composition, duration and temperature of emzymolysis, the types of osmotic stabilizer and the age of strains were screened to gain optimal protoplasts preparative condition through L<sub>16</sub> (4<sup>5</sup>) orthogonal test. Next, *Pleurotus ostreatus* and *Saccharomyces cerevisiae* protoplasts were inactivated by heat and UV, respectively. Duration and temperature of inactivation were screened for optimal conditions. Then, the optimal chemical fusion conditions, including fusion temperature and duration, pH value, Ca<sup>2+</sup> concentration and polyethylene glycol-4000 concentration, were screened through L<sub>16</sub> (4<sup>5</sup>) orthogonal test. At last, antagonism, morphological comparison of hypha and Random Amplified Polymorphic DNA were used to characterize the potential fusants, which was analyzed using NTSYS-PC software.

## Conclusions

183 regenerative strains were obtained and, among them, 14 strains were proved to be acquired from fusing *Pleurotus ostreatus* and *Saccharomyces cerevisiae* protoplast.

## **ARE DOG ENZYMES INVOLVED IN THE FORMATION OF THE YEAST TPS2 DELETION MUTANT'S RESIDUAL TREHALOSE?**

Z. Hefny<sup>1</sup>, I. Delorge<sup>1</sup>, F. Saleh<sup>2</sup>, P. Van Dijck<sup>1</sup>

<sup>1</sup>Department of Molecular Microbiology - Laboratory of Molecular Cell Biology, VIB KU Leuven, Leuven, Belgium

<sup>2</sup>Genetics Department, Assuit University, Assuit, Egypt

### **Background**

Trehalose is a disaccharide of which the concentration correlates very well with cellular stress resistance in yeast. It is synthesized in two enzymatic steps, where the intermediate trehalose-6-phosphate (Tre6P) is converted to trehalose by the enzyme Tps2. However, deletion of this gene does not completely abolish trehalose production. A possible explanation for this observation is that unspecific sugar phosphatases take over the function of the Tre6P phosphatase in a *tps2Δ* mutant. Screening the *Saccharomyces cerevisiae* proteome for enzymes containing the phosphohydrolase motifs present in Tps2 identified Dog1 and Dog2 as possible candidates. These enzymes are known to dephosphorylate 2-deoxyglucose-6-phosphate, but the natural substrate remains unknown.

### **Objectives**

Are Dog1 and Dog2 tre6P-phosphatase that are active in the absence of Tps2?

### **Methods**

We generated *S. cerevisiae* *DOG1* and *DOG2* deletion and over-expression mutants in the wild type and a *tps2Δ* background and determined heat stress tolerance and trehalose levels in these strains.

### **Conclusions**

The results obtained with the deletion strains seem to support our hypothesis. The *dog1Δ dog2Δ tps2Δ* mutant is more sensitive to heat stress than the *tps2Δ* mutant, which would indicate lower trehalose levels in the absence of the *DOG* genes. However, the results obtained with the *DOG1* and *DOG2* over-expression strains do not support the hypothesis, as trehalose levels and Tre6P-phosphatase activities are not increased in these strains. These results seem to indicate that the Dog1 and Dog2 may be involved in the expression of trehalose metabolism genes or may affect the enzymatic activity of these genes.

## **MYCELIUM AS BIO-BASED MATERIAL**

P. Krijgsheld<sup>1</sup>, C.E. Lukasiewicz<sup>1</sup>, F.A. Appels<sup>1</sup>, K.M.B. Jansen<sup>2</sup>, H.A.B. Wösten<sup>1</sup>

<sup>1</sup>Microbiology, Utrecht University, Utrecht, Netherlands

<sup>2</sup>Design engineering, TU Delft, Delft, Netherlands

### **Background**

One of the challenges of this century is to transform our economy into an eco-friendly and self-sustaining system. An innovative approach is the use of mycelium based materials.

### **Objectives**

The mycelium of the mushroom forming fungus *Schizophyllum commune* has great potential for developing such materials.

### **Methods**

Mycelium of *S. commune* was grown as a floating layer on liquid medium in the light or in the dark under ambient or a high concentration of CO<sub>2</sub>. Mycelia were dried and subjected to increasing tensile force. Their tensile modulus (E), elongation (ε) and stress of the sample at breaking point (σ) were measured. These values were rather low for the wild-type strain 4-39 that had been grown in the light at low CO<sub>2</sub> (E= 0.03±0.02 GPa, ε=0.75±0.28 %, σ: 0.44±0.31 MPa), resembling a crumble material that breaks easily. The properties of the wild-type strain 4.8b that had been grown under the same conditions resembled a flexible material (E: 0.22±0.08 GPa, ε=1.8±0.56 %, σ=3.5±0.9 MPa). Strain 4-39 and 4.8b grown in the light at high CO<sub>2</sub> had plastic-like and even stiffer properties, respectively (4-39: E=0.26± 0.12 GPa, ε= 1.15±0.49 %, σ=point 2.59±1.30 MPa; 4.8b: E=0.50±0.10 GPa, ε =1.13±0.21 %, σ= 5.58±1.65 MPa). Similar results were obtained with 4.8b and 4-39 when grown in the dark, regardless of CO<sub>2</sub> concentration.

### **Conclusions**

Taken together, physical properties of the mycelium is strain dependent and are affected by environmental growth conditions.

## **CHARACTERIZATION OF AIF5A (AEF5): AN EVOLUTIONARY CONSERVED TRANSLATION FACTOR**

A. La Teana<sup>1</sup>, F. Bassani<sup>1</sup>, T. Cacciamani<sup>1</sup>, L. Massacesi<sup>1</sup>, R. Galeazzi<sup>1</sup>, A. Wagner<sup>2</sup>, A. Orelli<sup>2</sup>, S.V. Albers<sup>2</sup>, D. Benelli<sup>3</sup>, P. Londei<sup>3</sup>

<sup>1</sup>DiSVA, Polytechnic University of Marche, Ancona, Italy

<sup>2</sup>Molecular Biology of Archaea, Max Planck Institute for terrestrial Microbiology, Marburg, Germany

<sup>3</sup>Dept BCE, University of Rome Sapienza, Rome, Italy

### **Background**

Protein synthesis is a complex process of fundamental importance in all cells during which a nucleotide sequence is translated into an amino acid sequence. The translation apparatus includes mRNA, ribosomes, aminoacyl-tRNAs and a number of translation factors, which assist all stages of the process. Some of the translation factors are conserved among Bacteria, Archaea and Eukarya.

One of the universally conserved factors is eIF5A, highly conserved between Eukarya and Archaea, with a orthologue (EF-P) in bacteria. It was initially identified as a translation initiation factor, but recent studies have established a role for both eIF5A and EF-P in translation elongation specifically in promoting the translation of polyproline containing proteins. The two proteins are both characterized by particular post-translational modifications, which are essential for their function: hypusination for eIF5A and lysinylation for EF-P.

### **Objectives**

Eukaryal and bacterial proteins have been extensively studied, while information on the archaeal homologues are extremely limited so in order to fill this gap we have started the characterization of the archaeal protein in *Sulfolobaceae*.

### **Methods**

We have produced the recombinant protein from *S. solfataricus* using two different expression systems: *E. coli* and *S. acidocaldarius* and the purified protein was then used in several *in vitro* functional tests.

### **Conclusions**

Results clarifying its function in the translation process will be presented and a molecular modelling will shed light on its interaction with the ribosome. In addition, we failed to obtain a knock-out strain in *S. acidocaldarius* proving that, as for the eukaryal and bacterial proteins, the gene product aIF5A is essential.

**AN INVESTIGATION OF BURKHOLDERIA CENOCEPACIA  
LIPOPOLYSACCHARIDE (LPS) MODIFICATION DURING CYSTIC FIBROSIS (CF)  
CHRONIC INFECTION AND ITS IMPACT ON HOST RESPONSE MODULATION**

L. McGuigan<sup>1</sup>, S. McClean<sup>1</sup>, M. Callaghan<sup>1</sup>

<sup>1</sup>Science, Institute of Technology Tallaght Dublin, Dublin, Ireland

**Background**

Bacterial species within the CF microbiome demonstrate adaptive strategies including altered expression of LPS. The structure of LPS governs its immuno-stimulatory potential. It is thus important to elucidate how LPS is modified during chronic infection and to determine its effects on host response modulation.

**Objectives**

We are investigating LPS extracted from four *B. cenocepacia* sequential isolates cultured from a CF patient during a 3.5 year infection to determine 1) if *B. cenocepacia* LPS is structurally modified during chronic infection and 2) the effect of any modification on the host response to LPS

**Methods**

The LPS was extracted using hot phenol extraction and analysed via SDS-PAGE. The LPS was incubated with CFBE41o-, 16HBE14o- and HL60 cells. The pro-inflammatory cytokines were subsequently analysed by ELISA. The LPS mutant was generated by deletion of BCAL2405, an O-antigen biosynthesis gene using a tri-parental mating method.

**Conclusions**

The O-antigen domain was present in the LPS from the first isolate but absent from the three later isolates. The LPS from the later isolates induced a significantly greater pro-inflammatory response from CFBE41o- cells ( $P < 0.001$ ), 16HBE14o- cells ( $P < 0.05$ ) and HL60 cells ( $P < 0.001$ ) when compared to LPS from the initial isolate. These data suggest that the loss of O-antigen in the later isolates may be responsible for the increased pro-inflammatory response. To verify this, we have successfully deleted the BCAL2405 gene from *B. cenocepacia* K56-2 which yielded LPS without the O-antigen and are currently investigating the pro-inflammatory potential of the mutant strain.

C. Bizet<sup>3</sup>, E. Stackebrandt<sup>3</sup>*

*<sup>1</sup>Department of Microbiology,*

*Waclaw Dabrowski Institute of Agricultural and Food Biotechnology, Warsaw, Poland*

*<sup>2</sup>,*

*The Leibniz Institute DSMZ - German Collection of Microorganisms and Cell Cultures  
GmbH, Braunschweig, Germany*

*<sup>3</sup>Steering Committee, MIRRI, Braunschweig, Germany*

**Background**

Millions of species of microorganisms on the earth, a large amount of them still undiscovered, are the source of biological diversity. Microorganisms are not only indispensable for life; they are basic for many human activities. Microorganisms are an essential part of the day-to-day work not only for scientists, but also for people working in the area of e.g. biotechnology, agriculture, industry, or medicine. Therefore, their economic value is very high. A large percentage of this microbial material is preserved in culture collections (CCs), in which their stability and reproducibility can be protected and through which they are (in most cases) available for other researchers.

**Objectives**

The implementation of the strategy on improved communication between user and provide has to be organised in a coordinated way. By arranging a major part of the CCs pro-active communication through the MIRRI portal the users will get a facilitated access to all requested information.

**Methods**

The main objectives of CCs and microbial resource centres (MRCs) are, besides conserving biodiversity, sharing microbial resources and associated data.

**Conclusions**

MIRRI has prepared strategy for communication between providers, which are Culture Collections with status of Microbiological Resource Centre (MRC) and users of microbiological resources. MRC are public resource centers specialized on microbial

raw material. They are capable of providing for users with culturable organisms such as micro-organisms, plant, animal and human cells, replicable parts of these (genomes, plasmids, viruses, cDNAs), as well as databases containing molecular, physiological and structural information relevant to these collections and related bioinformatics.

## **ELECTROTAXIS AND DUROTAXIS INFLUENCE THE BEHAVIOUR OF SINGLE CELL PSEUDOMONAS AERUGINOSA**

S. Neethirajan<sup>1</sup>, L.E.E. Preiss<sup>1</sup>

<sup>1</sup>Biological Engineering, University of Guelph, Guelph, Canada

### **Background**

*P. aeruginosa* motility plays a pivotal role in the colonization of surfaces, especially during the formation of antibiotic resistant biofilm structures. Endogenous electrical signals represent an important signaling mechanism that guides cell migration during wound healing, ultimately regulating the direction of cell movement. We report an approach to study the motility of single *P. aeruginosa* cells in microfluidic channels possessing different structural geometries, all with the flexibility of being able to manipulate chemical concentration gradients and electric fields to investigate changes in motility in response to specific stimuli.

### **Objectives**

This study is designed to examine the interplay between surface rigidity, mechanical, and electrical cues to pave the way for improvements in the design of anti-fouling surfaces for biomedical applications and to identify new ways to inhibit bacterial biofilm growth through motility restriction.

### **Methods**

Three different microfluidic devices with varying geometries (circular, semi-circular shell, and square cut out respectively) were developed using soft-lithography and nanofabrication tools for the analysis of durotaxis and galvanotaxis of single cell *P. aeruginosa*.

## Conclusions

With the use of fabricated microfluidic platforms, we studied the impact of spatial restrictions, rigidity of the substrate medium, and the impact of external electrical fields on *Pseudomonas aeruginosa* motility. Spatial restrictions resulted in a significant reduction in single-cell velocity and the distance travelled, but did not affect the trajectory directness. *Pseudomonas aeruginosa* single cells showed a preference for an environment with increased stiffness, which was independent of the time of exposure to the electric field.

## **MARINE-DERIVED *PENICILLIUM* IN KOREA: DIVERSITY, ENZYME ACTIVITY, AND ANTIFUNGAL PROPERTIES**

M.S. Park<sup>1</sup>, J. Fong<sup>1</sup>, S.Y. Oh<sup>1</sup>, K. Kwon<sup>2</sup>, J.H. Sohn<sup>3</sup>, Y.W. Lim<sup>1</sup>

<sup>1</sup>*School of Biological Sciences, Seoul National University, Seoul, Korea*

<sup>2</sup>*Marine Biotechnology Research Division,  
Korea Institute of Ocean Science and Technology, Ansan, Korea*

<sup>3</sup>*Department of Biofood Materials, Silla University, Pusan, Korea*

### **Background**

In Korea, approximately 100 *Penicillium* species have been recorded. Many of these species were isolated from soil, and some were found to be associated with post-harvest diseases of plant products. However, the diversity of marine-derived *Penicillium* in Korea is poorly understood relative to terrestrial species.

### **Objectives**

We explored the diversity of marine-derived *Penicillium* in Korea by isolating *Penicillium* species from various marine substrates and identifying them using a multigene phylogenetic approach. We also evaluated the biological activity (extracellular enzyme activity and antifungal activity against the plant pathogens) of the strains.

### **Methods**

The diversity of marine-derived *Penicillium* from Korea was investigated using morphological and multigene phylogenetic approaches (ITS, *BenA*, *RPB2*). We tested for the extracellular enzyme activity of alginase, endoglucanase, and beta-glucosidase, and antifungal activity against two plant pathogens (*Colletotrichum acutatum* and *Fusarium oxysporum*).

### **Conclusions**

A total of 184 strains of 36 *Penicillium* species were isolated, with 27 species being identified. The most common species were *P. polonicum* (19.6 %), *P. rubens* (11.4 %), and *P. chrysogenum* (11.4 %). The diversity of *Penicillium* strains isolated from soil and marine macroorganisms was higher than the diversity of strains isolated from seawater. While many of the isolated strains showed alginase and beta-glucosidase activity, no endoglucanase activity was found. More than half the strains (50.5 %) showed antifungal activity against at least one of the plant pathogens tested. The

relatively high proportion of strains that showed antifungal and enzyme activity demonstrates that marine-derived *Penicillium* have great potential to be used in the production of natural bioactive products for pharmaceutical and/or industrial use.

**Background**

In fish farming the benefits of probiotics have been usually inferred appraising the effects observed on the host, namely growth, survival and immune response, and not through the direct assessment of probiotics dynamics and role in the host gut microbiota. Currently, there is the urgency to develop accurate tools to assess and weigh up the dynamics of autochthonous bacteria and probiotics in the gut microbiota, in order to better understand the effects of probiotics, prebiotics and synbiotics in aquaculture production.

**Objectives**

This work aimed to identify novel taxa-specific DNA markers for *B. licheniformis*, one of the most used probiotics in aquaculture, and develop culture-independent methods for detection and quantification of these bacteria and understand their modulation role of fish-gut microbiota.

**Methods**

Several putative *B. licheniformis*-specific DNA markers were selected using the

CUPID and Insignia databases. These utilities, combined with comprehensive genomic studies and dedicated experimental validation, allowed the selection of four DNA markers used for detection and quantification of *B. licheniformis* by multiplex PCR and qPCR, respectively, in digesta samples of fish gut samples.

### **Conclusions**

The selected DNA markers were successfully applied for detection and quantification of *B. licheniformis* in fish gut. These results are a contribution for a better understanding of *B. licheniformis* dynamics in gut microbiota of farmed fish in response to different diets, but also during disease outbreaks. This knowledge is an added-value to optimize and implement best practices for aquaculture.

**ICLIKVAL: COMMUNITY RESOURCE FOR CURATING THE VAST WEALTH OF MICROBIOLOGY-RELATED LITERATURE THROUGH THE POWER OF CROWDSOURCING**

T.D. Taylor<sup>1</sup>, N. Kumar<sup>1</sup>

<sup>1</sup>*Core for Precise Measuring and Modeling,  
RIKEN Center for Integrative Medical Sciences, Yokohama, Japan*

**Background**

There are currently over 24 million citations in PubMed, including many related to microbiology research. Searching this vast resource does not always give desirable or complete results due to several factors. Ideally, every citation should include a complete set of keywords that describe the original article in detail; however, this would require countless hours of manual curation.

**Objectives**

Our goal is to make manual curation 'fun', social, and self-correcting, thus enriching resources like PubMed so that users are able to extract more valuable and relevant results. We developed a web-based open-access tool for manual curation of PubMed articles, and other media types, using a crowdsourcing approach. We encourage the use of ontology terms and support them as auto-suggest keyword terms, but we do not restrict users to these so as not to impose any limitations on the annotation types.

Non-English annotation is also supported.

## Methods

We constructed a cross-browser and platform-independent application using a NoSQL database. Users perform searches, mark articles for review, load PDFs into the viewer, select annotations (values) within the text, and add appropriate keywords (keys). Article-specific comments can be made, key-value pairs can be edited and rated, live chats between users can be conducted, annotations can be added via Twitter, etc.

## Conclusions

The more annotations that accumulate in the database the more reliable the results. We implemented a REST API to make the annotations easily accessible to the research community. We hope this will become the default resource for community-based curation of all online microbiology-related and scientific literature.

**THE RISK OF SERIOUS INFECTIONS WITH THE USE OF RITUXIMAB IN RHEUMATOID ARTHRITIS. RESULTS FROM A META-ANALYSIS OF RANDOMISED CLINICAL TRIALS.**

L. Velez-Nandayapa<sup>1</sup>, A. Bhattacharya<sup>2</sup>, C. Parikh<sup>2</sup>

<sup>1</sup>Pharmacovigilance, Dr. Reddy's Laboratories SA Biologics, Basel, Switzerland

<sup>2</sup>Pharmacovigilance, Dr. Reddy's Laboratories Ltd Biologics Development Centre, Hyderabad, India

**Background**

The association between serious infections (SINFs) and the use of rituximab in patients with non-Hodgkin's lymphoma has been clearly confirmed; but, uncertainty remains about the association of SINFs with rituximab in rheumatoid arthritis (RA).

**Objectives**

Our study, a systematic review and meta-analysis (SR&MA), aimed to provide reliable assessment of the risk of SINFs and rituximab in RA (RTX-RA).

**Methods**

This SR&MA was registered with the PROSPERO database (CRD42014015655) as protocol for a complete evaluation of the safety profile of RTX-RA. The search strategy involved randomised clinical trials using rituximab in RA, published from January 1990 to December 2014 in Medline, EMBASE and Cochrane Library databases. The outcomes evaluated were: the number of adverse events and SINFs reported as outcomes of interest. Odds ratio (OR) analysis, 95% confidence intervals (CI95%) and p values (chi-squared) were calculated; heterogeneity was assessed using the I<sup>2</sup> test. Sub-analysis by doses (500 vs 1000 mg) and type of infection were performed.

Results: Eight publications (3,272 subjects) were selected for review and 5 publications (2,249 subjects) were included in the meta-analysis; the number of events of SINFs in rituximab+methotrexate (RTX-MTX) group vs control (placebo+methotrexate) were 35/1,465 vs 27/784. We found no evidence of association between RTX-MTX and SINFs (OR 0.64; CI95% 0.39-1.04; p=0.74; I<sup>2</sup>=0.000). Similarly, our sub-analysis by RTX doses (500 vs 1000 mg) and type of infection, showed no evidence of association.

## **Conclusions**

Our results suggest no evidence of association between RTX-MTX in RA and SINFs. Further studies are needed to confirm our findings.

**AUDIT OF NOTIFIABLE DISEASE REPORTING IN A GENERAL MEDICINE  
DEPARTMENT OF A DISTRICT GENERAL HOSPITAL IN THE UK**

S. Wallace<sup>1</sup>, R. Hilbert<sup>1</sup>

<sup>1</sup>*Diabetes and Endocrinology, St Helier's Hospital, London, United Kingdom*

**Background**

“The purpose of notification [of infectious diseases] is to enable the prompt investigation, risk assessment and response to cases...that present a significant risk to human health. Notification has the secondary benefit of providing data for use in... epidemiological surveillance...”<sup>1</sup> Doctors in England have a duty to notify diseases as a legislative requirement.

**Objectives**

To establish whether general medical doctors in a hospital in London are appropriately reporting notifiable diseases according to 2010 health protection guidance.

**Methods**

Notifiable diseases managed in adult secondary care were selected: acute meningitis, invasive group A streptococcus, enteric fever, meningococcal septicaemia, malaria.

Adult patients diagnosed with these diseases between May and October 2013 were identified via the microbiology database and clinical coding. The notes were reviewed for documentation of discussion with public health or the notification form, and the time this occurred relative to diagnosis/clinical suspicion.

**Conclusions**

24 cases of notifiable diseases were identified and of these 17 notes were located (7 malaria, 9 viral meningitis, 1 *Salmonella typhi*). There was 1 documented notification (6% of 17 notes), with no identifiable date.

Possible causes of the low notification rate include: poor awareness among doctors that it is their responsibility, lack of knowledge which diseases are notifiable, uncertainty which clinician/clinical team has responsibility for notification, and difficulty in locating forms on the hospital intranet.

Measures to improve notification include implementation of electronic notification reminders with results, staff education and more easily accessible information/notification form on intranet.

**CHARACTERIZATION OF THE LIPOPOLYSACCHARIDE TRANSPORT MACHINE IN ESCHERICHIA COLI: IN SEARCH OF A FUNCTION FOR THE ELUSIVE COMPONENT LPTC**

M. Benedet<sup>1</sup>, F. Falchi<sup>1</sup>, S. Puccio<sup>2</sup>, C. Di Benedetto<sup>1</sup>, C. Peano<sup>2</sup>, A. Polissi<sup>3</sup>, G. Dehò<sup>1</sup>

<sup>1</sup>*Dipartimento di Bioscienze, Università degli Studi di Milano, Milan, Italy*

<sup>2</sup>*Istituto di Tecnologie Biomediche, Consiglio Nazionale delle Ricerche, Milan, Italy*

<sup>3</sup>*Dipartimento di Biotecnologie e Bioscienze, Università di Milano-Bicocca, Milan, Italy*

**Background**

The lipopolysaccharide (LPS) transport (Lpt) system is responsible for transferring LPS from the periplasmic surface of the inner membrane (IM) to the outer leaflet of the outer membrane (OM), where it plays a crucial role in OM selective permeability. In *E. coli* seven essential proteins form the Lpt trans-envelope complex: LptBFG form the IM ABC transporter; LptDE form the OM translocon for final LPS delivery; LptC, an IM-anchored protein with a periplasmic domain, interacts with the IM ABC transporter, the periplasmic protein LptA, and LPS<sup>(1)</sup>. Although essential, LptC can tolerate several mutations and its role in LPS transport is unclear.

**Objectives**

To clarify the functional role of LptC in the Lpt machine.

**Methods**

By plasmid shuffling we obtained viable mutants missing *lptC*; genome sequencing of  $\Delta$ *lptC* mutants revealed single amino acid substitutions at a unique position (\*) in the IM component *lptF*; in complementation tests, *lptF*<sup>\*</sup> mutants suppress lethality of both  $\Delta$ *lptC* and *lptC* conditional expression mutants.

**Conclusions**

Our data show that a specific mutation in LptF can compensate the lack of LptC and suggest that LptC may serve as a chaperon of the Lpt machine assembly and/or activity rather than an essential structural component. Studies are in progress to understand the structure and function of the six-protein Lpt<sup>\*</sup> system.

## **A NOVEL SCENARIO OF OPRF REGULATION IN PSEUDOMONAS AERUGINOSA**

A.L. Boechat<sup>1</sup>, R.L. Baldini<sup>1</sup>

<sup>1</sup>Biochemistry Department, Institute of Chemistry - USP, São Paulo, Brazil

### **Background**

OprF, the major porin of *Pseudomonas aeruginosa*, has an immunogenic potential and a large set of information regarding its functions, including its role in the outer membrane structure, interaction with lipopolysaccharide and association with virulence and quorum sensing. In the prototype strain PAO1, transcription of *oprF* was reported to be dependent on sigma 70 and the alternative ECF sigma factor SigX.

### **Objectives**

As we have shown that SigX overexpression in PA14 leads to a growth defect, we assessed *oprF* transcription regulation in order to verify if this effect is due to OprF overexpression and to characterize *oprF* regulation in PA14.

### **Methods**

*oprF* promoter activity was determined via *-lacZ* reporter fusions integrated in the chromosome or by relative *oprF* mRNA levels (qRT-PCR) in wild-type PA14, *sigX* null mutant or in PA14 overexpressing *sigX* from an inducible promoter in a multicopy plasmid (ALB04 strain). *oprF* and *sigX* promoters activity was also assessed in the PA14/*rpoS* mutant by  $\beta$ -galactosidase assays.

### **Conclusions**

Surprisingly, we found that all *oprF-lacZ* promoters activity decreased in ALB04 and the amount of OprF did not increase in a proteomic analysis. The *sigX* null mutant has wild-type levels of *oprF* mRNA, contrasting to other SigX-induced genes. We have also found that transcription of *oprF* occurs mainly via the region containing the putative sigma 70-dependent promoter. Although *oprF* transcription regulation is independent of SigX in PA14, both *oprF* and *sigX* transcription is dependent on the general stress sigma factor RpoS. The data presented here discloses a novel

scenario of *oprF* regulation in *P. aeruginosa*.

**TRIGGER ENZYME PEPA FROM *E. COLI*, A TRANSCRIPTIONAL REPRESSOR THAT GENERATES POSITIVE SUPERCOILING**

D. Charlier<sup>1</sup>, P. Nguyen Le Minh<sup>1</sup>, M. Nada<sup>2</sup>

<sup>1</sup>Research group of Microbiology, Vrije Universiteit Brussel, Brussels, Belgium

<sup>2</sup>Institut de Génétique et Microbiologie, Université Paris-Sud centre Universitaire d'Orsay, Orsay, France

**Background**

Hexameric *E. coli* Leucine-aminopeptidase A (PepA) is a trigger enzyme endowed with catalytic activity and DNA-binding properties prominent in the resolution of ColE1 and pSC101 plasmid multimers and transcriptional regulation of the *carAB* operon, encoding the unique carbamoylphosphate synthase of *E. coli*. Previous studies by DNase I footprinting and atomic force microscopy (AFM) had both indicated a pronounced deformation of the *carAB* control region upon PepA binding, suggestive of DNA wrapping. On the basis of this observation and previous work, PepA was believed to play a major, although merely architectural role in the formation of the synaptic complexes involved in site-specific DNA recombination and in the elaboration of a higher order regulatory protein-*carP1* DNA complex.

**Objectives**

Here we further investigate the molecular mechanism of PepA-mediated transcriptional regulation of the *carP1* promoter.

**Methods**

To this aim we use single-round *in vitro* transcription and DNA topology assays.

**Conclusions**

The *in vitro* transcription assays performed with supercoiled template and purified components demonstrate that PepA is a repressor in its own right, which specifically inhibits transcription initiation at *carP1*. Furthermore, DNA topology studies performed on artificial DNA mini-circles by means of various topoisomerases with different substrate specificities demonstrate that PepA binding induces positive supercoiling. Such topological changes may serve as a regulatory mechanism that allows swifter response and multi-layered control of promoter activity in concert with other regulatory components known to be involved in the control of *carP1*.

**Background**

-

**Objectives**

-

**Methods**

-

**Conclusions**

Streptomyces are filamentous bacteria that grow by apical tip extension. This process is orchestrated by the tropomyosin-like protein DivIVA, which is present at hyphal tips. DivIVA interacts with various proteins, among which the cellulose synthase-like protein CslA. This protein synthesizes a  $\beta$ -(1,4)-glycan, which is thought to protect growing apices that are continuously being remodeled. To obtain further insight in the role of DivIVA and CslA in polar growth and morphogenesis, we have recently generated so-called *Streptomyces* L-forms that can grow without peptidoglycan. As a consequence, such cells are round and lack any obvious form of polarity. L-form cells have recently been suggested to resemble primordial cell, based on the observation that their growth and proliferation do not require the canonical cytoskeletal or cell division proteins. Instead, their proliferation can merely be explained by physical processes. However, our work on *Streptomyces* L-forms suggests that these cells require glycans, such as those formed by CslA, for their growth. Such glycans might have served for protection of early life forms, before the modern cell wall was invented. We have recently isolated an L-form mutant strain, which readily switches back and forth between mycelial and L-form growth. This mutant with the capability to re-synthesize peptidoglycan is crucial to understand which genes play an essential role in proliferation of L-forms, but also to unravel the mechanism underlying filamentous growth.

**THE ESCHERICHIA COLI MEMBRANE PROTEIN INSERTASE YIDC ASSISTS IN THE BIOGENESIS OF PENICILLIN BINDING PROTEINS**

A. de Sousa Borges<sup>1</sup>, J. de Keyzer<sup>1</sup>, A. J. M. Driessen<sup>1</sup>, D. Scheffers<sup>1</sup>

<sup>1</sup>Molecular Microbiology, GBB, Groningen, Netherlands

**Background**

Membrane proteins need to be properly inserted and folded in the membrane in order to perform a range of activities that are essential for the survival of bacteria. The Sec translocon and the YidC insertase are responsible for the insertion of the majority of proteins into the cytoplasmic membrane. YidC can act in combination with the Sec translocon in the insertion and folding of membrane proteins. However, YidC also functions as an insertase independently of the Sec translocon for so-called YidC-only substrates. In addition, YidC can act as a foldase and promote the proper assembly of membrane protein complexes.

**Objectives**

Here, we investigate the effect of *Escherichia coli* YidC depletion on the assembly of Penicillin Binding Proteins (PBPs), that are involved in cell wall synthesis.

**Methods**

Active PBPs were assessed by substrate binding and total protein amount was determined by immunoblotting.

**Conclusions**

YidC depletion hardly affects the total amount of the specific cell division PBP3 (FtsI) in the membrane, but the amount of active PBP3 is strongly reduced. Similar reductions in the amounts of active PBP2 and PBP4 were observed, while the levels of active PBP1A/1B and PBP5 were essentially similar. PBP1B and PBP3 disappeared from higher Mw bands upon YidC depletion, indicating that YidC might play a role in PBP complex formation. Taken together, our results suggest that the foldase activity of YidC can extend to the periplasmic domains of membrane proteins.

## **INTERPLAY BETWEEN UVRD HELICASE AND RECJ EXONUCLEASE IN NEISSERIA GONORRHOEAE**

D. Ganguli<sup>1</sup>, K.C. Manjunath<sup>1</sup>, R. Dhanaraju<sup>1</sup>, N.R. Desirazu<sup>1</sup>

<sup>1</sup>Biochemistry, Indian Institute of Science, Bangalore, India

### **Background**

*Neisseria gonorrhoeae* is an obligate human pathogen causing gonorrhea. It mainly employs homologous recombination to repair double stranded breaks in DNA. The involvement of mismatch repair helicase, UvrD in homologous recombination is debatable till date. Evidences have implied that it could be an anti-recombinase or promote RecFOR pathway. In this study, a detailed biochemical characterization of UvrD from *N. gonorrhoeae* and its interaction with RecJ exonuclease (NgoRecJ) which is involved in resection of DNA ends during RecFOR pathway of recombination has been carried out.

### **Objectives**

1. To biochemically characterize UvrD from *Neisseria gonorrhoeae* (NgoUvrD).
2. To study the physical interaction between NgoUvrD and NgoRecJ exonuclease.
3. To elucidate the functional role of this interaction, if any.

### **Methods**

Both the proteins were purified by Ni<sup>2+</sup>-NTA followed by Heparin-Sepharose chromatography. The unwinding and exonuclease activities were monitored using gel based assays. ATPase assays were carried out using TLC. Protein-protein interaction studies were done using Far-western analysis.

### **Conclusions**

Biochemical analysis suggested that NgoUvrD behaves as a dimer in solution, exhibits 3'-5' polarity on ssDNA and can unwind blunt end duplex DNA as well as different recombination intermediates such as overhang containing DNA and Holliday junction in ATP dependent manner. It was observed that NgoRecJ and NgoUvrD

physically interact with each other. Interestingly, the ATPase activity of NgoUvrD shows 5- fold stimulation in presence of NgoRecJ. This observation for the first time shows that UvrD in complex with RecJ exonuclease might be involved in the initial step of RecFOR pathway, thereby promoting recombination.

**Bacterial cell biology**

## **A NEW PROGRAMMED CELL DEATH PATHWAY IN ESCHERICHIA COLI**

L. Dewachter<sup>1</sup>, N. Verstraeten<sup>1</sup>, M. Fauvart<sup>1</sup>, J. Michiels<sup>1</sup>

<sup>1</sup>Centre of Microbial and Plant Genetics, KU Leuven, Leuven, Belgium

### **Background**

Programmed cell death (PCD) in bacteria has long been controversial due to the belief that only multicellular organisms would benefit from this kind of altruistic behavior. However, over the past decade, compelling experimental evidence has established a consensus that such pathways exist in bacteria.

### **Objectives**

Recently, we discovered that expression of a mutant isoform of an essential GTPase, ObgE, causes rapid cell death in *Escherichia coli*. The physiological changes that occur upon expression of this mutant protein (ObgE\*) and the genetic basis of this cell death pathway were investigated.

### **Methods**

Besides a clear loss of viability, fluorescence microscopy and FACS analysis revealed that a large array of apoptotic markers – including chromosome condensation, DNA fragmentation, loss of membrane potential and exposure of phosphatidylserine on the cell surface – can be found upon expression of ObgE\*, indicating that ObgE\* triggers a PCD pathway. Previous reports of bacterial PCD attribute essential roles to either RecA and its function in the SOS response or to the toxic effect of the *mazEF* TA module. However, by analysing viability and physiological changes upon ObgE\* expression in *recA* and *mazEF* mutant strains, all currently known bacterial PCD mechanisms could be excluded.

### **Conclusions**

ObgE\* triggers a PCD pathway in *E. coli* that differs fundamentally from all other previously described bacterial PCD pathways. Further research into the genetic and molecular basis of this new PCD mechanism may prove useful in unraveling the function and mechanisms of genetically encoded cell death pathways in bacteria.

**Bacterial cell biology**

## **MUTATIONAL ANALYSIS OF LPTA, AN ESSENTIAL LPS-TRANSPORT PROTEIN IN ESCHERICHIA COLI**

F. Falchi<sup>1</sup>, P. Sperandeo<sup>2</sup>, E. Maccagn<sup>2</sup>, C. Peano<sup>3</sup>, S. Puccio<sup>3</sup>, A. Poliss<sup>2</sup>, G. Dehò<sup>1</sup>

<sup>1</sup>Dipartimento di Bioscienze, Università degli Studi di Milano, Milan, Italy

<sup>2</sup>Dipartimento di Biotecnologie e Bioscienze, Università di Milano-Bicocca, Milan, Italy

<sup>3</sup>Istituto di Tecnologie Biomediche, Consiglio Nazionale delle Ricerche, Milan, Italy

### **Background**

Lipopolysaccharide (LPS) is the major outer leaflet constituent of the Gram-negative bacteria outer membrane (OM). In *E. coli* LptA protein is a periplasmic component of the LPS transporter (Lpt) made of seven components (LptABCDEFG), which ferries LPS from the inner membrane (IM) to OM. LptA interacts with LptC and chaperons LPS through the periplasm. The crystal structure of LptA has been solved and some residues involved in binding LPS and other Lpt proteins have been identified.

### **Objectives**

1. To characterize LptA structure-function.
2. To identify interactions between genes/proteins implicated in OM functionality.

### **Methods**

1. We generated by site-directed mutagenesis *lptA41*, a quadruple mutant in four conserved amino acids potentially involved in LPS or LptC binding; the mutant exhibited increased sensitivity to hydrophobic compounds (Shc phenotype). This suggests that *lptA41* impairs LPS transport thus leading to OM permeability defects.
2. We selected suppressors of *lptA41* Shc phenotype and sequenced the genomes of two mutants (Sup102 and Sup103) to identify the suppressing mutations.

### **Conclusions**

Sup102 harbors a small in-frame deletion in *vacJ*, which codes for a putative OM lipoprotein involved in maintaining OM asymmetry. Sup103 harbors an additional amino-acid substitution (M112I) in LptA41 (*lptA42* allele) and a nonsense mutation in *mdoH*, a gene encoding a glycosyltransferase involved in periplasmic membrane-derived oligosaccharides synthesis.

These results reveal two different strategies adopted by the cell to overcome OM defects caused by defective LPS transport.

**INVESTIGATIONS ON THE BIOLOGICAL SIGNIFICANCE OF BURKHOLDERIA CENOCEPACIA J2315 HFQ2 PROTEIN ABILITY TO BIND DNA**

J.R. Feliciano<sup>1</sup>, S.A. Sousa<sup>1</sup>, A.M. Grilo<sup>1</sup>, J.H. Leitão<sup>1</sup>

<sup>1</sup>*Department of Bioengineering, Instituto Superior Técnico, Lisbon, Portugal*

**Background**

Accumulating evidence has shown that Hfq is a RNA chaperone involved in post-transcriptional regulation, mediating the interaction of small RNAs with their target mRNAs. However, besides its regulatory role in the translation of bacterial mRNA, in *Escherichia coli*, Hfq is also a DNA-binding protein and is associated with nucleoid DNA. Bcc bacteria are among the few prokaryotes that encode in their genomes two distinct and functional Hfq-like proteins, the 79 aa Hfq and the 188 aa Hfq2. Both proteins bind RNA, however bioinformatics predictions suggested that Hfq2 is able to bind DNA by means of its C-terminal domain.

**Objectives**

The present study aims to unveil the biological significance of Hfq2 C-terminus predicted ability to bind to DNA.

**Methods**

A DNA binding domain was bioinformatically predicted for Hfq2 and DNA binding assays were performed using purified His-tagged Hfq or Hfq2 and the *araC* promoter of pMLBAD plasmid. Electrophoretic Mobility Shift Assays indicates that Hfq2 protein, but not Hfq, is able to bind this DNA fragment. Hfq2 derivatives with complete, partial and absent C-terminus extension were produced to confirm if this region confers the ability to bind DNA. To identify the DNA sequences to which Hfq2 specifically binds, a ChIP-seq strategy is currently being performed, using *B. cenocepacia* J2315 fragmented total DNA.

**Conclusions**

Contrasting with Hfq, a putative DNA binding domain was identified in Hfq2 and our results showed that this protein is able to bind DNA. Ongoing work is being performed to identify the DNA sequences and the specificity of DNA-Hfq2 interactions.

## **KNOCKOUT OF MINC LEADS TO BRANCHING IN XANTHOMONAS CITRI**

G.C. Dantas<sup>1</sup>, H. Ferreira<sup>1</sup>

<sup>1</sup>Biochemistry and Microbiology, Instituto de Biociencias UNESP, Rio Claro, Brazil

### **Background**

*Xanthomonas citri* (Xac) is the causal agent of citrus-canker, a disease that affects citrus plants worldwide, leading to low productivity, culminating in considerable economic losses to orange growers. There is no treatment for citrus canker, and eradication of plants is the only reliable method to prevent the spread of Xac to areas considered free of the disease. We reported on the use of new cell-division inhibitors as an alternative to prevent Xac growth, and plant colonization (Dantas *et al.* *JBacteriol* **195**:85). To further extend the characterization of cell division in Xac, we started the investigation of the *minC* gene.

### **Objectives**

To study *minC* encoded by Xac and its function in site division selection at cell division

### **Methods**

The *minC* gene was deleted using allele exchange. The knocked-out strain was complemented with a replicon containing *minC* under the control of the arabinose promoter. Pathogenicity tests were carried out by infiltration of sweet orange (*Citrus sinensis* (L.) Osbeck). Cell morphology was evaluated using DIC microscopy

### **Conclusions**

Xac deleted for *minC* exhibited the classic delta-*minC* phenotypes: production of minicells, cell filamentation, and asymmetric/misplaced division constrictions along the rods. Surprisingly, Xac delta-*minC* produced branching, a phenotype observed for *Escherichia coli* deleted for PBP5 and other low-molecular-weight penicillin-binding proteins. Complementation of delta-*minC* with *minC* supplied *in trans* restituted the wild-type division phenotype. Irrespective of the phenotype, the delta-*minC* strain was competent to colonize the host citrus and produce disease symptoms. Altogether, data shows that *minC* is essential for normal cell division in Xac.

**CSRA PARTICIPATES TO ENVELOPE HOMEOSTASIS IN ESCHERICHIA COLI**

T. Hallaert<sup>1</sup>, E. Seyll<sup>1</sup>, S. Zedek<sup>1</sup>, D. Monteyne<sup>1</sup>, D. Perez-Morga<sup>1</sup>, L. Van Melderen<sup>1</sup>

<sup>1</sup>DBM, Université Libre de Bruxelles, Brussels, Belgium

**Background**

The CsrA protein (Carbon Storage Regulator A) is a global post-transcriptional regulator controlling carbon fluxes and group behaviors in bacteria. Our preliminary SEM analyses revealed that an *E. coli* mutant deleted for the *csrA* gene displays a strongly altered morphology. Cells are of small size as compared to the wild-type cells and present an irregular surface and blebs.

**Objectives**

Cell envelope is the first line target for physicochemical injuries arising from the environment. This complex structure also supports fundamental processes such as energy production and nutrient acquisition. To preserve envelope homeostasis bacteria have evolved intricate stress response pathways. The objective is to evaluate whether envelope stress responses are induced in  $\Delta csrA$  mutant and if it is the case, what are the underlying molecular mechanisms.

**Methods**

Expression of effectors belonging to the 5 well-described envelope stress response pathways (*bae*, *psp*, *cpx*, *sigmaE*, *rsc*) were analyzed by RT-qPCR. Envelope integrity was evaluated by measuring sensitivity to specific compounds.

**Conclusions**

We have shown that in the  $\Delta csrA$  mutant, the Psp and Rcs pathways are constitutively induced. Rcs pathway monitors outer membrane integrity while Psp that of the inner membrane. This mutant also shows a high sensitivity to deoxycholate and vancomycin, indicating an increased permeability of the outer membrane. In addition, the  $\Delta csrA$  mutant accumulates high ROS concentration, which might participate to *psp* activation. ROS accumulation might thus represent the link between metabolism and envelope defects. This hypothesis is currently under investigation.

**IDENTIFICATION OF THE MULTI-COMPONENTS DNA UPTAKE SYSTEM OF NATURALLY TRANSFORMABLE LEGIONELLA PNEUMOPHILA USING TRANSCRIPTOMIC ANALYSIS.**

P.A. Juan<sup>1</sup>, X. Charpentier<sup>1</sup>

<sup>1</sup>Team « *Signaling and genetics of competence development in bacterial pathogens* »  
CNRS UMR5240 « *Microbiology Adaptation and Pathogenesis* »,  
Claude Bernard Lyon 1 University, Villeurbanne, France

**Background**

Natural transformation is a major mechanism of horizontal gene transfer that is already well-studied in historical Gram-positive models whereas knowledge on Gram-negative bacteria remains sparse. *Legionella pneumophila* is a Gram-negative bacterium that develops, under specific growth conditions or stress, competence for natural transformation, a genetically programmed state allowing bacteria to take up free exogenous DNA and integrate it in their genome. The *L. pneumophila* genome shows a large repertoire of virulence-associated eukaryotic-like genes. Natural transformation offers a plausible route for acquisition of foreign genes contributing to the emergence of this pulmonary pathogen.

**Objectives**

The DNA uptake system allowing *L. pneumophila* to take up DNA and recombine it into its chromosome remains unknown. The aim of our study was to identify this system and determine its contribution to the infectious process.

**Methods**

We used a transcriptomic analysis to identify genes up-regulated in an hypercompetent mutant of *L. pneumophila*. We performed a systematic targeted mutagenesis of these up-regulated genes to test their involvement in transformability and DNA uptake. We used immunofluorescence microscopy to visualize components of the DNA uptake system.

**Conclusions**

Our work allowed us to identify the main components of the *Legionella* DNA uptake system which involves a type IV transformation pilus dedicated to natural transformation. We propose a model of the DNA uptake system that unexpectedly relies on the actin-like protein MreB. These progresses pave the way for a more detailed analysis of the DNA uptake system dynamics and more broadly for a better understanding of Gram-negative bacteria transformation systems.

## **THE MOLECULAR BASIS OF REGULATION OF TNR DNA-BINDING ACTIVITY IN BACILLUS SUBTILIS**

A. Kayumov<sup>1</sup>, K. Fedorova<sup>1</sup>, K. Forchhammer<sup>2</sup>

<sup>1</sup>Department of Genetics, Kazan Federal University, Kazan, Russia

<sup>2</sup>Institut für Mikrobiologie und Infektionsmedizin, Eberhard Karls University Tübingen, Tübingen, Germany

### **Background**

TnrA is a master transcriptional regulator of nitrogen metabolism in *Bacillus subtilis*. Its activity was suggested to be regulated by binding to the feedback-inhibited glutamine synthetase (GS). Recently we showed that TnrA also binds to the PII-like GlnK protein.

### **Objectives**

Understanding of TnrA activity regulation via interaction with GlnK or GS

### **Methods**

*In vivo* cross-linking, Surface Plasmon Resonance, ITC

### **Conclusions**

We found that *in vivo* TnrA binds both proteins, but in contrast to the suggested mechanism, TnrA binds GS also under nitrogen-poor conditions. SPR analysis demonstrated that GS in the absence of feed-back inhibitors efficiently binds TnrA, but 1 mM glutamine strengthens the binding 2-fold. By contrast, ATP strongly repressed TnrA-GS interaction, whereas 1 mM glutamine completely neutralized this negative effect. In presence of L-methionine sulfoximine (MSX), a transition-state analogue of GS, GS–TnrA interaction was also stimulated. However, in presence of MSX and ATP, where MSX is phosphorylated and irreversibly fixes GS in transition state, GS binding to TnrA was completely abolished. Isothermal titration calorimetry revealed competitive binding of glutamine and ATP to GS. Therefore, we suggest two conformations of GS for TnrA interaction: (1) a TnrA-binding “N-state”, stabilized by glutamine or its analogue MSX and (2), a non-binding “A-state”, which reflects the conformation of the enzyme in the catalytic transition state or bound with ATP in

absence of glutamine. We propose that GS changes between the “N-state” and “A-state”. In vivo, this transition depends on the intracellular glutamine:ATP ratio and thus regulates the amount of active TnrA.

**A VIBRIO VUNIFICUS ORTHOLOG OF ESCHERICHIA COLI RRAA  
CONTRIBUTES TO DIFFERENTIAL RNASE E-MEDIATED MRNA DECAY**

D. Kim<sup>1</sup>, S. Lee<sup>1</sup>, B. Lee<sup>1</sup>, M. Joo<sup>1</sup>, J.H. Yeom<sup>1</sup>, H.M. Kim<sup>1</sup>, M. Lee<sup>1</sup>, K. Lee<sup>1</sup>

<sup>1</sup>Life Science, Chung-Ang University, Seoul, Korea

**Background**

Endoribonuclease E (RNase E) plays an important role in the degradation and processing of RNAs in *Escherichia coli*. Expression levels and enzymatic activity of RNase E are tightly controlled by self-cleavage of *rne* mRNA and regulators of RNase activity, RraA and RraB. The marine pathogenic bacterium *Vibrio vulnificus* also contains homologs of RNase E and RraA, designated as RNase EV, RraAV1, and RraAV2.

**Objectives**

In this study, we show that RraAV1 actively inhibits the enzymatic activity of RNase EV on a subgroup of substrate RNAs.

**Methods**

Notably, RNase EV cleavage on *rne* mRNA encoding RNase EV was greatly affected by RraAV1 *in vitro* and *in vivo*, contributing to autoregulation of both expression and activity of RNase EV.

**Conclusions**

Our findings suggest that RraAV1 plays an active role in differential RNase E-mediated mRNA decay.

**THE STUDY OF BIOGENESIS FEATURES OF OUTER MEMBRANE VESICLES  
PRODUCED BY *LYSOBACTER* SP. XL1**

*I. Kudryakova*<sup>1</sup>, *N. Suzina*<sup>2</sup>, *I. Tsfasman*<sup>1</sup>, *N. Vasilyeva*<sup>1</sup>

<sup>1</sup>*Laboratory of Microbial Cell Surface Biochemistry,  
G.K. Skryabin Institute of Biochemistry and Physiology of Microorganisms,  
Pushchino, Russia*

<sup>2</sup>*Laboratory of Cytology of Microorganisms,  
G.K. Skryabin Institute of Biochemistry and Physiology of Microorganisms,  
Pushchino, Russia*

**Background**

Gram-negative bacteria produce outer membrane vesicles (OMVs) containing biologically active proteins. Despite of extensive information about OMVs biogenesis available, this process is still not enough clear. Gram-negative bacterium *Lysobacter* sp. XL1 forms OMVs containing bacteriolytic endopeptidase L5, – one of five bacteriolytic enzymes secreted by this microorganism. Knowledge about OMVs biogenesis by bacteria of *Lysobacter* genus is rather restricted.

**Objectives**

The objective of our work was the study of factors causing biogenesis of OMVs produced by *Lysobacter* sp. XL1.

**Methods**

Methods were used: fractionation of OMVs using sucrose density gradient centrifugation, electronic microscopy including immunocytochemistry with the protein A-gold, SDS-PAGE electrophoresis, Western blotting assay, protein and 2-keto-3-deoxyoctonate assays, thin-layer chromatography, determination of lytic OMVs action.

**Conclusions**

Enzyme L5 was found to be localized inside of the lightest OMVs fraction which differed in protein composition from other fractions. The L5 protein was revealed at certain loci of bacterial outer membrane (OM). OMVs were produced from these loci. Thereby, secreting enzyme L5 took part in biogenesis of OMVs. OM was shown to contain cardiolipin, phosphatidylethanolamine, phosphatidylglycerol. OMVs contained the only one major phospholipid, – cardiolipin. Thus, OMVs of *Lysobacter* sp. XL1

were formed from loci enriched with cardiolipin. It has been offered the model of vesicles biogenesis produced by *Lysobacter* sp. XL1. Besides, OMVs containing protein L5 were shown to lyse broad range of opportunistic and pathogenic bacteria including multidrug-resistant strains. The data obtained are the basis for development of artificial vesicular structures – liposomes – containing bacteriolytic enzymes of *Lysobacter* sp. XL1 as a new effective antimicrobial preparation.

## **HOW TO DEAL WITH COPPER? CAULOBACTER CRESCENTUS' POINT OF VIEW.**

E. Lawarée<sup>1</sup>, S. Gillet<sup>1</sup>, F. Tilquin<sup>1</sup>, J.Y. Matroule<sup>1</sup>

<sup>1</sup>Microorganisms Biology Research Unit, UNamur, Namur, Belgium

### **Background**

Despite its essential role as a trace element, copper becomes toxic at higher concentrations, prompting bacteria to develop a tight regulation of copper homeostasis in order to survive.

### **Objectives**

The alphaproteobacterium *Caulobacter crescentus* lives in poor and contaminated environments and gives rise to two distinct cell types upon cell division: a motile swarmer cell and a sessile stalked cell. The swarmer cell is thought to seek optimal environments in order to differentiate into a stalked cell, which will in turn replicate its DNA and divide. This dimorphic cell cycle likely provides a better adaptation to various stresses such as an increase of copper concentration.

### **Methods**

We found that the swarmer and the stalked cells respond differently to a toxic copper concentration. Copper slows down swarmer to stalked cell transition and the further initiation of DNA replication, whereas copper-treated stalked cells undergoes a normal DNA replication. Accordingly, copper concentration in swarmer cells is 3 fold higher than in the stalked cells. We showed that copper homeostasis in the stalked cells is ensured by the conserved PcoAB<sub>Cc</sub> system, which is also able to sustain copper detoxification in the swarmer cells when constitutively expressed in trans, thereby restoring a proper swarmer to stalked cell transition.

### **Conclusions**

Both *C. crescentus* cell types regulate copper homeostasis differently in order to progress throughout the cell cycle.

**AN RNASE G-MEDIATED PATHWAY FOR PATHOGENICITY IN SALMONELLA  
TYPHIMURIUM**

S. Lee<sup>1</sup>, D. Kim<sup>1</sup>, B. Lee<sup>1</sup>, M. Joo<sup>1</sup>, M. Lee<sup>1</sup>, H.M. Kim<sup>1</sup>, K. Lee<sup>1</sup>, J. Bae<sup>2</sup>

<sup>1</sup>Life Science, Chung-Ang University, Seoul, Korea

<sup>2</sup>Pharmacy, Chung-Ang University, Seoul, Korea

**Background**

Endoribonuclease G (RNase G) is involved in rRNA processing and degradation of a subgroup of mRNAs in *Escherichia coli*. However, little is known about physiological role of this enzyme.

**Objectives**

We observed RNase G expression-dependent alterations in the survival rate of *Salmonella* Typhimurium cells in both macrophages and mice. These alterations were strongly associated with expression levels of *rbs* mRNA encoding ribose transport system, which was identified as a substrate of RNase G.

**Methods**

Analysis of polycistronic *rbs* mRNA identified two RNase G cleavage sites in the 5'-untranslated region of *rbsA*. The induced *rbs* expression during macrophage infection coincided with decreased rates of bacterial infection and survival.

**Conclusions**

Our study shows that RNase G mediates a previously uncharacterized pathway that involves ribose transport system as a key factor for the survival and virulence of *S. Typhimurium* in host cells.

### **Background**

Bacteria belonging to *Corynebacteriales*, an order of actinomycetes group that includes corynebacteria, mycobacteria, nocardia and rhodococci possess an atypic, complex multilayered envelope. This envelope is composed of a heteropolymer of peptidoglycan (PG) and arabinogalactan (AG) covalently associated to an outer membrane mostly composed of mycolic acids. We explored the biogenesis of *Corynebacteriales* cell envelope by using a genome-wide transposon mutagenesis approach targeting *Corynebacterium glutamicum*. For this purpose, we developed an effective immunological screen that allows us to rapidly identify bacteria exhibiting an altered cell envelope.

### **Objectives**

We wanted to identify missing actors of the *Corynebacteriales* envelope biosynthesis pathways. One interesting mutant of our library was chosen and characterized in this study.

### **Methods**

We identified the gene inactivated by the transposon and constructed a strain in which this gene was deleted. We performed analyses of the main cell wall compounds of this mutant strain, i.e. PG, AG and mycolic acids. A physiological study was also conducted and in particular a screen for the sensitivity of this mutant to various antibiotics.

### **Conclusions**

Our analyses revealed that this mutant was impaired in the PG biosynthesis pathway and more specifically in a modification of this polymer that also occurs in mycobacteria species and in other *Corynebacterium* pathogens species such as *Corynebacterium jeikeium*. Lack of this modification led to morphologically-altered

cells with high susceptibility to lysozyme and to antibiotics of the  $\beta$ -lactam family.

<sup>2</sup>Unité PMM, Institut Pasteur, Paris, France

**Background**

Beneficial interactions between gut microbiota and the host have been revealed but little is known at the molecular level. To identify bacterial factors that account for these symbiotic interactions, we recently carried out reverse genetics of *Lactobacillus casei* which allowed identification of 47 key genes for *L. casei* establishment in the gut (Licandro-Seraut et al. 2014. PNAS).

**Objectives**

Now, we aim to decipher the functions encoded by these key genes in the gut context.

**Methods**

Some of the *L. casei* mutants have been investigated individually with regard to their morphology, metabolism, gene regulation...

**Conclusions**

A mutant for the predicted cysteine synthase was investigated to demonstrate the metabolic role of the cysteine synthase. Also, it was less resistant than the wild type to several stresses. Three mutants for three genes in an operon encoding a two-component system and a penicillin-binding protein were characterized. Analysis of primary data suggests that these genes are involved in the cell surface modulation and particularly in the regulation of peptidoglycan hydrolases which are required for the bacteria protection in the intestinal environment.

**Bacterial cell biology**

**Role of PprM in catalase gene expression of the radiation-resistant bacterium, *Deinococcus radiodurans***

S. Lim<sup>1</sup>, S. Jeong<sup>1</sup>, D. Kim<sup>1</sup>

<sup>1</sup>*Research Division for Biotechnology, Korea Atomic Energy Research Institute, Republic of Korea*

Background: *Deinococcus radiodurans* (*D. radiodurans*) is a poly-extremophilic organism, capable of tolerating a wide variety of different stresses such as gamma/UV radiation, desiccation, and oxidative stress. It is known that PprI (DR0167) is a global regulator, which is essential for its extreme resistance, and cold shock protein homologue PprM (DR0907) is presumably controlled by PprI. PprI mutation decreases the catalase activity of *D. radiodurans*, but, the effect of PprM on catalase has not been studied.

Objectives: We investigated the role of PprM, which is involved PprI-mediated signal transduction, in catalase gene expression.

Methods: First, we performed an in-gel catalase activity assay to observe activity of three catalases (DR1998, DRA0146, and DRA0259) independently in wild type, pprM, pprI, and pprI/pprM double mutant strains. We also constructed catalase mutants of *D. radiodurans* to identify the catalase that is affected by PprM and purified catalases to check the activity in vitro. The mRNA and protein levels of catalase genes were monitored by using real-time PCR and western blot assays in various mutant strains.

Conclusions: Among three catalases, we confirmed that DRA0146 does not have catalase activity. Deletion of pprM decreased catalase activity and protein level of DR1998, but not its mRNA level. We could not observe an additional reduction of the DR1998 protein in the pprI/pprM double mutants compared to pprI or pprM single mutants. These suggest that PprI can affect DR1998 via PprM, and PprM may exert its effect on DR1998 at the post-transcriptional level.

**PHYSIOLOGICAL GLUCOSE CONCENTRATIONS TRIGGER LPS PRODUCTION AND VIRULENCE IN A ACINETOBACTER BAUMANNII.**

F. Longo<sup>1</sup>, E. Rossi<sup>1</sup>, C. Peano<sup>2</sup>, L. Barbagallo<sup>3</sup>, S. Jaillon<sup>3</sup>, A. Petrelli<sup>2</sup>, C. Garlanda<sup>3</sup>, P. Landini<sup>1</sup>

<sup>1</sup>Bioscience, University of Milan, Milan, Italy

<sup>2</sup>Institute of Biomedical Technologies, National Research Council, Segrate, Italy

<sup>3</sup>Experimental Immunopathology, Humanitas Research Hospital, Rozzano, Italy

**Background**

*Acinetobacter baumannii* is an emerging pathogen involved in severe infections and outbreaks mainly occurring in clinical settings. Multi-drug resistance and ability to form biofilm could play a role in its persistence in hospital settings.

The present study analyzes an *A. baumannii* clinical strain, belonging to the SMAL clone, isolated in an Italian hospital.

**Objectives**

The aim of this work is to study the effect of glucose, at a concentration similar to human blood, on production of biofilm determinants in *A. baumannii*.

**Methods**

Genome sequence and transcriptome analysis were performed by using deep sequencing and RNA-seq techniques (Illumina).

Transcription of selected genes were measured by using transcriptional fusions with the reporter gene *lacZ*.

Exopolysaccharide (EPS) production was analysed by EDTA extraction and phenol-sulfuric acid quantification.

Lipopolysaccharide (LPS) production was measured using tricine SDS-PAGE.

Cytokine production was tested by ELISA analysis.

**Conclusions**

Genome sequence of the analysed strain showed identity with the sequence type 78, epidemic in several Mediterranean countries.

Growth in the presence of glucose showed higher EPS production; consistently, transcriptome analysis suggested a deep modification of gene expression in presence of glucose. In particular, several genes involved in EPS and LPS biosynthesis and modification were up-regulated in presence of glucose. Remarkably, *A. baumannii* grown in presence of glucose appears to release LPS, which in turn stimulates cytokine production in macrophages.

Our results suggest that glucose at physiological concentrations might act as a trigger for LPS production and virulence in *A. baumannii*.

## **ACTION OF MOLECULAR CHAPERONES DEDICATED TO THE MATURATION OF REDUCTIVE DEHALOGENASES**

C. Grob<sup>1</sup>, F. Palmieri<sup>1</sup>, G. Buttet<sup>1</sup>, J. Maillard<sup>1</sup>

<sup>1</sup>ENAC-LBE, Ecole polytechnique fédérale de Lausanne, Lausanne, Switzerland

### **Background**

Reductive dehalogenases (RDases) are key enzymes in organohalide respiration (OHR) as they catalyze the reduction of halogenated compounds such as tetrachloroethene (PCE), a major environmental pollutant. RDases contain a corrinoid and two iron-sulfur cofactors and require cofactor assembly and maturation prior to transport across the cytoplasmic membrane via the Twin-arginine translocation (Tat) pathway. Recently, a new dedicated Tat molecular chaperone, PceT, has been identified that seems to act in the maturation of the PCE RDase (PceA) of *Dehalobacter restrictus* and members of *Desulfitobacterium hafniense*.

### **Objectives**

This work intends to study the molecular action and specificity of PceT and other members of the RdhT chaperone family on the maturation of RDases.

### **Methods**

Heterologous co-expression of the *pceA* and *pceT* genes will be investigated in *E. coli* in various growth and induction conditions in order to evaluate the effect of PceT on the production, stability and cofactor load of PceA. Additional general molecular chaperones will be also considered here. A detail characterization of the protein-protein interaction between PceT and PceA will be obtained by a combination of *in vitro* biochemical approaches. Site-directed mutagenesis of conserved residues of RdhT proteins should allow identifying key amino acids in the recognition of, i.e. action on, PceA.

### **Conclusions**

Preliminary data already suggested that PceT mainly recognizes the Tat signal peptide of PceA, therefore resembling the paradigmatic Tat specific chaperones (TorD, NapD,...) as they play a major role in quality control of their cognate redox enzyme allowing sufficient time for cofactor assembly and folding.

**FEMS-3017**

**IDENTIFICATION OF A PUTATIVE CHROMOSOMAL REPLICATION ORIGIN FROM *BDELLOVIBRIO BACTERIOVORUS* AND ITS INTERACTION WITH THE INITIATOR PROTEIN DnaA**

Ł. Makowski<sup>1</sup>, R. Donczew<sup>1</sup>, C. Weigel<sup>2</sup>, A. Zawilak-Pawlik<sup>1</sup>, J. Zakrzewska-Czerwińska<sup>1</sup>

<sup>1</sup>Microbiology Department,

Institute of Immunology and Experimental Therapy Polish Academy of Sciences, Wrocław, Poland

<sup>2</sup>Department of Life Science Engineering, HTW-Berlin, Berlin, Germany

**Background**

*Bdellovibrio bacteriovorus* is a small Gram-negative, obligate predatory bacterium that attacks and invades other Gram-negative bacteria, including pathogens such as *Helicobacter pylori* or *Pseudomonas aeruginosa*. Its life cycle consists of two stages – non-replicative attack phase, wherein predator searches for prey and replicative growth phase, wherein it actively divides in host periplasm. Initiation is the first and strictly regulated step of bacterial chromosome replication, which leads to duplication of the genetic material in bacterial cells prior to their division.

**Objectives**

Our aim was to identify and characterize the key elements of initiation of chromosome replication in *B. bacteriovorus*: origin of chromosomal replication (*oriC*) and initiator protein.

**Methods**

Using *in silico* analysis, we identified the *oriC* region, which is located downstream of the *dnaA* gene; the *B. bacteriovorus oriC* (*BdoriC*) contains eight putative DnaA boxes. Comprehensive *in vitro* studies using EMSA, DMS footprinting and SPR revealed that the DnaA protein specifically binds all eight DnaA boxes. By P1 nuclease assay we localized the DNA unwinding elements (DUE) where DNA replication starts. In addition, we compared the architecture of the DnaA–*oriC* complexes (orisomes) in homologous (*oriC* and DnaA from *B. bacteriovorus*) and heterologous (*BdoriC* and DnaA from prey, *E. coli* or *P. aeruginosa*) systems. Interestingly, we demonstrated that DnaA proteins from preys (relatively distantly related from *B. bacteriovorus*) not only specifically bind *BdoriC*, but also unwind DNA at the DUE.

**Conclusions**

To conclude, we identified the *oriC* of *B. bacteriovorus* and characterize in details its interaction with the replication initiator protein.

**Bacterial cell biology**

## **LINK BETWEEN PTS<sup>Ntr</sup> OF BRUCELLA ABORTUS AND ITS CENTRAL METABOLISM**

S. Moussa<sup>1</sup>, T. Barbier<sup>1</sup>, K. Willemart<sup>1</sup>, J.J. Letesson<sup>1</sup>

<sup>1</sup>Research Unit in Biology of Microorganisms, UNamur, Namur, Belgium

### **Background**

*Brucella*, an ALPHA2-proteobacteria, is the etiological agent of brucellosis that generates a worldwide zoonosis. It can infect human and will lead, if not treated, to a chronic infection with severe complications.

To proliferate, bacteria need to get carbon sources from their environment and the phosphotransferase system (PTS) contributed to this goal. It displays regulating functions in carbon metabolism and forms a phospho-relay, ending with the entry and concomitant phosphorylation of a sugar.

*Brucella abortus* possesses a paralogous system called Nitrogen PTS (PTS<sup>Ntr</sup>), acting the same way except that no sugar entry occurs. Starting from the phosphoenolpyruvate, the phosphoryl group is successively transferred on histidine residues of Enzyme I (EI<sup>Ntr</sup>) (*ptsP* gene), then to the NPR (*ptsO*) protein and finally to EIIA<sup>Ntr</sup> (*ptsN*) or EIIA<sup>MAN</sup> (*ptsM*).

### **Objectives**

We were interested in the identification of a link between central metabolism and the *B. abortus* PTS<sup>Ntr</sup>.

### **Methods**

We have generated the knockout mutant of those 4 protagonists and studied their bacterial growth behavior on media containing different single carbon source. We found that *B. abortus* was mainly able to grow on sugar entering the pentose phosphate pathway. Interestingly, compared with the wild type strain, the *ptsP* (EI<sup>Ntr</sup>), *ptsO* (NPR) and *ptsN* (EIIA<sup>MAN</sup>) mutants shows a growth defect on those sugars while the *ptsM* (EIIA<sup>Ntr</sup>) mutant grows better. Moreover, point mutation study on NPR protein shows that phosphorylation state of the histidine residue seems to be the main actor controlling growth behavior.

### **Conclusions**

It suggests a role of the *Brucella* PTS<sup>Ntr</sup> in the regulation of central metabolism.

**FEMS-0958**

**Bacterial cell biology**

**ENRICHMENT FOR G1-ARRESTED DAUGHTER CELLS OF BRUCELLA ABORTUS**

T. Ong<sup>1</sup>, X. De Bolle<sup>1</sup>, J. Letesson<sup>1</sup>

<sup>1</sup>URBM, UNamur, Namur, Belgium

**Background:** In HeLa cells and RAW264.7 macrophages, the facultative intracellular pathogen *B. abortus* blocks its growth and its cell cycle at the G1 stage during the first hours of infection (M. Deghelt *et al.*). G1 bacteria are proposed to have an increased ability to invade these host cells. Therefore, it would be interesting to prepare a bacterial population enriched with G1-arrested daughter cells to investigate *B. abortus* cell cycle in culture and in interaction with the host cells.

**Objectives:** Searching the best method for synchronizing the cell cycle of *B. abortus* at the G1 stage. Then, testing G1 bacteria for their potential invasion of host cells.

**Methods:** Nutrient downshift method was used to produce G1-arrested cells of *Sinorhizobium meliloti* (De Nisco *et al.*). Our results indicate that this is not an effective way to synchronize G1-arrested daughter cells of *B. abortus*. However, culture of *B. abortus* in rich medium until the early stationary phase resulted in a reproducible enrichment in G1 bacteria (about 70%), as assessed by flow cytometry. Another method called “baby machine”, that immobilize a mixed population of bacteria labelled with NHS-biotin (*N*-hydroxysuccinimido-biotin) by streptavidin-coated magnetic beads, was set up to recover only G1 bacteria. We expected that the unipolar growth will be resumed on the beads in rich medium, allowing the enrichment of daughter cells at the G1 stage of the cell cycle.

**Conclusions:** Culture of *B. abortus* in rich medium yielded a partial and transient enrichment of G1 bacteria. It seems that the unipolar nature of growth is no more detectable when bacteria are labelled with NHS-biotin. Other labelled compounds for “baby machine” method are currently tested and analysed to achieve G1 bacteria of *B. abortus*.

## **CHARACTERIZATION OF LMO1521 AND LMO2591 MUREIN HYDROLASES FROM LISTERIA MONOCYTOGENES**

R. Ostrowski<sup>1</sup>, H. Wach<sup>1</sup>, M. Popowska<sup>1</sup>

<sup>1</sup>Department of Applied Microbiology, University of Warsaw Faculty of Biology, Warsaw, Poland

### **Background**

*L. monocytogenes* is a gram-positive, foodborne pathogen causing listeriosis with a high mortality rate (1). This species is widespread in nature which is connected with a high number of surface proteins. Very important class of these proteins are murein hydrolases (autolysins), involved in several crucial processes, including: cell growth, turnover of cell wall components, cell separation and division, biofilm formation, protein secretion, autolytic activity of some antibiotics and pathogenicity (2). This work was supported by a grant from the National Center of Science 2013/09/B/NZ6/00710

### **Objectives**

Determination of the activity and substrate specificity of two autolysins from *L. monocytogenes*: Lmo1521 and Lmo2591.

### **Methods**

Lmo1521 and Lmo2591 proteins with C-terminal hexa-His-Tags were expressed in *E. coli* BL21 using expression vector pET-28a (Novagen). These proteins were purified on Ni-NTA Agarose column (Qiagen), and the isolation of the correct proteins was verified by immunoblotting. The effect of overexpression of the proteins on host cells morphology (*E. coli* BL21) was tested using scanning microscopy. To investigate activity we have performed spectrophotometric and zymographic assay (using different purified bacterial cell walls).

### **Conclusions**

Bioinformatic analysis showed the presence of a N-acetylmuramoyl-L-alanine domain in Lmo1521, N - acetylmuramidase domain in Lmo2591 and GW-motif in both. Our results indicate muralytic activity of the studied proteins against different bacterial cell walls. We have also determined the substrate specificity of these two autolysins.

**THE EFFECT OF RSD, THE ANTI-SIGMA FACTOR OF SIGMA 70, ON BIOFILM FORMATION AND MOTILITY IN ESCHERICHIA COLI**

Y.H. Park<sup>1</sup>, M.K. Seo<sup>1</sup>, J.W. Lee<sup>2</sup>, C.K. Yoon<sup>1</sup>, J.H. Yoon<sup>2</sup>, Y.R. Kim<sup>1</sup>, Y.J. Seok<sup>2</sup>

<sup>1</sup>Department of Biological Sciences and Institute of Microbiology,  
Seoul National University, Seoul, Korea

<sup>2</sup>Department of Biophysics and Chemical Biology, Seoul National University, Seoul, Korea

**Background**

In bacteria,  $\sigma$  subunit of RNA polymerase (RNAP) directs transcription initiation. The regulation of  $\sigma$  activity is important for fine tuning of gene expression.  $\sigma$  activity is determined by their cellular level, affinity for core RNAP, and interactions with regulatory proteins. In *Escherichia coli*, housekeeping  $\sigma$  factor,  $\sigma^{70}$ , has the highest affinity for core RNAP and is the most abundant  $\sigma$  factor. Rsd, regulator of sigma D, binds specifically to  $\sigma^{70}$  and it has been known as an anti- $\sigma$  factor of  $\sigma^{70}$ .

**Objectives**

Even though Rsd is known as an anti- $\sigma^{70}$  factor, no specific phenotype has been associated with deficiency or overexpression of Rsd to date. In this study, we found new phenotypes of the *rsd* mutant.

**Methods**

Cell-to-cell autoaggregation assay

Biofilm formation assay

Semi-solid agar assay for assessment of motility

**Conclusions**

An *rsd*-deficient mutant cell sank much faster than wild type. In spite of its increased cell aggregation, biofilm formation decreased in the *rsd* mutant. We found a protein of ~ 43 kDa whose expression was significantly higher in the *rsd* mutant compared to wild-type. Peptide mass fingerprinting revealed that this enriched protein is antigen 43 (Ag43) encoded by *agn43*, whose transcription is  $\sigma^{70}$ -dependent. Also, one protein band increased in wild-type and Rsd-overexpressing strains compared to the *rsd* mutant. Mass spectrometry identified this protein band as the flagellin protein FliC. Based on these results, we propose that Rsd decreases the transcriptional level of *agn43* through the regulation of  $\sigma^{70}$  activity and consequently it influences the biofilm formation and motility.

## **STRUCTURAL CHARACTERIZATION OF THE DNA UPTAKE MACHINERY IN GRAM-POSITIVE BACTERIA**

S. Pieretti<sup>1</sup>, R. Perez<sup>1</sup>, A. Canals<sup>1</sup>, M. Coll<sup>1</sup>

<sup>1</sup>*Structural and Computational Biology,*

*Institute for Research in Biomedicine (IRB Barcelona), Barcelona, Spain*

### **Background**

Horizontal Gene Transfer (HGT) is an evolutive mechanism by which entire genes are transferred among bacterial cells, thus enabling an immediate adaptation to new environmental conditions. HGT has obvious implications for human health as it is used by pathogenic microorganisms – even among different species– during the spread of virulence factor and antibiotic resistance. Three main routes can be distinguished: *conjugation* (plasmid transfer through the direct interaction of two bacterial cells), *transduction* (bacteriophage-mediated DNA transfer) and *transformation* (uptake of naked DNA from the environment). The term DNA Uptake Pump (DUP) refers to the translocating machinery used by bacteria to incorporate naked DNA from the environment to the cytoplasm during bacterial transformation.

### **Objectives**

The specific aim of this project is to determine the structure of the DNA uptake pump responsible for bacterial transformation in gram-positive bacteria using X-ray crystallography. This machinery is mainly formed by a DNA receptor, a transmembrane channel that mediates DNA translocation across the cytoplasmic membrane and an ATPase which pulls DNA into the cytoplasm at the expense of ATP.

### **Methods**

We adopted a high-throughput approach to achieve our goals. We designed 96 constructs from five different species with several solubility-enhancing fusion partners and affinity tags. The constructs can be divided into three groups: putative soluble constructs, fragments containing trans-membrane helices and full-length integral membrane proteins.

### **Conclusions**

We already have cloned the target genes and have tested them for soluble expression in *E. coli*. Large scale purification and preliminary crystallization trials are in progress for the soluble constructs.

## **CELL SHAPE CONSERVATION AND REGULATION IN BACTERIA**

L. Renner<sup>1</sup>, A. Amir<sup>2</sup>

<sup>1</sup>*IBP, Leibniz-Institut für Polymerforschung Dresden e.V., Dresden, Germany*

<sup>2</sup>*Department of Physics, Harvard University, Cambridge, USA*

### **Background**

Why bacteria have evolved and maintained their specific shapes is one central question in bacterial cell biology. Rod-shaped bacteria cells are remarkable in keeping their geometry and shape. How this shape is regulated is still mostly uncharted territory.

### **Objectives**

We are setting out to understand how and if rod-shaped bacteria are maintaining their rod shape when subjected to mechanical deformation. We explore how mechanical force changes the bacteria morphology and the consequences for bacteria after the mechanical force is released. The behaviour of proteins, that are involved in maintaining rod-shape, e.g. MreB, Mbl, is analyzed microscopically to understand if mechanical deformation can influence protein localization.

### **Methods**

With the help of soft lithography we are applying microfabrication tools to create microenvironments to manipulate the shape of bacteria. To analyse the shape morphology and protein localization we are using different types of microscopy and automated image analysis tools.

### **Conclusions**

Rod-shaped bacteria are maintaining their rod shape in response to mechanical deformations. Cells return to their original shape with a fast rate in cell wall recovery. It appears that the rod shape is a strong evolutionary feature and tightly controlled.

**GLYCAN FORAGING SYSTEMS SIGN THE ADAPTATION OF  
CAPNOCYTOPHAGA CANIMORSUS TO THE DOG'S MOUTH.**

F. Renzi<sup>1</sup>, P. Manfred<sup>2</sup>, M. Dol<sup>1</sup>, J. Fu<sup>3</sup>, S. Vincent<sup>3</sup>, G.R. Cornelis<sup>1</sup>

<sup>1</sup>Biology, Université de Namur, Namur, Belgium

<sup>2</sup>Infection Biology, Biozentrum der Universität Basel, Basel, Switzerland

<sup>3</sup>Chemistry, Université de Namur, Namur, Belgium

**Background**

*Capnocytophaga canimorsus* (Cc) are Gram-negative bacteria that are part of the normal flora of dogs' mouth and can cause rare but severe infections in humans which have been in contact with a dog.

Cc grow in co-culture with eukariotic cells by harvesting surface glycans via the PUL5 encoded Gpd complex. PUL5 mutant bacteria show a reduced growth and display coccoid forms, which strongly resemble *E. coli* mutant bacteria that are unable to synthesize aminosugars, and are deficient in peptidoglycan synthesis.

We thus speculated that Cc's arrest of growth and cell rounding would be due to starvation of aminosugars.

**Objectives**

Here we address the question why Cc rely on host aminosugars and how they retrieve them from their niche, the dog's mouth.

**Methods**

Cc strain 5 (Cc5) genome analysis revealed that Cc5 could not synthesize N-acetylglucosamine (GlcNAc) because of the lack of two enzymes which convert glucosamine into GlcNAc. Heterologous expression of these enzymes as well as supplementation with GlcNAc completely restored the growth and abolished the formation of coccoid forms.

**Conclusions**

We show that *C. canimorsus* cannot synthesize GlcNAc and thus rely on exogenous GlcNAc which they retrieve by foraging glycans from mucin and N-linked

glycoproteins through two different apparatuses, Muc and Gpd, both related to the *Bacteroides* starch utilization system (Sus).

We propose that the GlcNAc auxotrophy reflects the adaptation of *C. canimorsus* to its host and ecological niche, the dog's mouth.

## **STREPTOMYCES PEUCETIUS VAR. CAESIUS AND ITS GLUCOKINASES: WHAT THEIR PHYSIOLOGICAL RELEVANCE IS?**

D. Rocha-Mendoza<sup>1</sup>, B. Ruiz-Villafán<sup>1</sup>, S. Sánchez-Esquivel<sup>1</sup>

<sup>1</sup>*Biología Molecular y Biotecnología, UNAM Instituto de Investigaciones Biomédicas, México D.F., Mexico*

### **Background**

*Streptomyces peucetius* var. *caesius*, a relevant industrial strain overproduces the antitumor, doxorubicin. As reported for other secondary metabolites, doxorubicin production is also repressed by glucose. In streptomycetes, the glucokinase (ATPGlk), participates in the process of carbon catabolite repression (CCR). However, the mechanism by which this enzyme exerts its regulatory role, has not been elucidated. In this bacterium, we have reported the presence of an additional glucokinase (PPGlk), which uses polyphosphate as its phosphate donor group. Contrary to what is observed for other *Streptomyces* such as *S. peucetius*, *S. coelicolor*, *S. lividans* and *S. thermocarboxydus*, in *S. peucetius* var. *caesius*, PPGlk activity is higher compared to that of ATPGlk. A similar situation has been reported for a chlortetracycline overproducer strain of *Streptomyces aureofaciens*. So far, the implications of the presence of two glucokinases in development and physiology of the genus *Streptomyces* are unknown.

### **Objectives**

To evaluate the role of both glucokinases in the physiology of *S. peucetius* var. *caesius*, their participation in the CCR, morphological development and synthesis of anthracyclines.

### **Methods**

ATPglk::aac(3)/V and PPglk::aadA mutants were obtained by replacing the genes for an apramycin and a streptomycin resistance cassette (*aadA*), respectively. Strains were grown in different carbon sources, and their ATPGlk, PPGlk, b-galactosidase and glycerol kinase activities were determined. Total anthracyclines and morphological differentiation (microscopy) were also evaluated.

### **Conclusions**

The ATPglk::aac(3)/V mutant showed inability to grow in high glucose concentrations and exhibited deregulation in CCR. In regard to the parent strain, the mutant growth and production of anthracyclines, was delayed on solid medium.

## **REGULATION OF DIFFERENTIATION AND ANTIBIOTIC PRODUCTION IN STREPTOMYCES GRISEUS**

M. Szilágyi-Bónizs<sup>1</sup>, D. Lukács<sup>1</sup>, S. Biró<sup>1</sup>

<sup>1</sup>Human Genetics, Medical University of Debrecen, Debrecen, Hungary

### **Background**

The genus *Streptomyces* comprises soil-dwelling, filamentous bacteria having great biotechnological significance since these bacteria produce 75% of the known antibiotics. Autoregulatory molecules play a key role in controlling antibiotic production and morphological differentiation. In *Streptomyces griseus* A-factor (2-isocapryloyl-3R-hydroxymethyl-γ-butyrolactone) proved to be significant as the A-factor negative (AFN) mutant had a non-differentiating phenotype.

### **Objectives**

Previous studies showed that the A-factor biosynthetic *afsA* gene was functional and transcribed in the AFN strain. Our aim is to understand the background of the AFN phenotype.

### **Methods**

In this study the production of AfsA protein, aerial mycelium, spores, extracellular protease and antibiotics was followed on rich and minimal medium. To detect the presence of AfsA by Western blotting we produced the AfsA as a GST-fusion protein in *Escherichia coli*. The purified AfsA was used for immunization of rabbits.

### **Conclusions**

The AFN strain did not form aerial mycelium on rich medium due to the lack of A-factor but spores were formed from the substrate mycelium. Aerial mycelium emergence and sporulation were observed on minimal medium in AFN although the production of spores, extracellular protease and antibiotics were decreased compared to the control strain. The AfsA protein was detected in the AFN strain. These data confirm the hypothesis that the presence of AfsA is not enough for normal A-factor production and A-factor is essential for the aerial mycelium but not for spore formation on rich medium. Moreover our data support the existence of a crosstalk between the A-factor mediated and the starvation induced pathway.

**DECIPHERING THE METABOLISM OF THE GLYCAN LIPID CARRIER, THE UNDECAPRENYL-PHOSPHATE**

G. Manat<sup>1</sup>, R. Auger<sup>1</sup>, F. Delbrassine<sup>2</sup>, M. El Ghach<sup>2</sup>, A. Bouhss<sup>1</sup>, F. Kerff<sup>2</sup>,  
D. Mengin-Lecreulx<sup>1</sup>, T. Touzé<sup>1</sup>

<sup>1</sup>Biology, Institut for Integrative Biology of the Cell, Orsay, France

<sup>2</sup>Biology, Centre of Protein Engineering, Liège, Belgium

**Background**

The biogenesis of bacterial cell-wall polymers (e.g., peptidoglycan, lipopolysaccharides, teichoic acids) requires undecaprenyl-phosphate (C<sub>55</sub>-P). The glycan units are linked to this lipid at the inner face of the membrane. Thereafter, the membrane intermediate is translocated in order to transfer the glycan unit to the periplasmic side, where the glycan moiety is transferred to the growing polymer. The process releases undecaprenyl-pyrophosphate (C<sub>55</sub>-PP). C<sub>55</sub>-P originates from the dephosphorylation of C<sub>55</sub>-PP, itself generated by *de novo* synthesis and recycling.

**Objectives**

Identification and biochemical characterisation of bacterial C<sub>55</sub>-P phosphatase.

**Methods**

Genetics: construction of deletion mutants. Biochemistry: membrane protein purification and characterisation (enzymatic activity, membrane topology, mutagenesis, structure).

**Conclusions**

Two families of membrane proteins exhibit C<sub>55</sub>-PP phosphatase activity: BacA and members of the PAP2 super-family. *Escherichia coli* possesses one BacA and three PAP2 proteins (PgpB, YbjG and LpxT), raising the question of the significance of such a multiplicity. LpxT catalyses the transfer of the C<sub>55</sub>-PP phosphate group onto the lipid A moiety of the lipopolysaccharides (LPS), yielding C<sub>55</sub>-P and lipid A-1diP. The role of this LPS modification is under investigation (e.g., antibiotic resistance, ion homeostasis, innate immunity). This raises a tantalising hypothesis that the other C<sub>55</sub>-PP phosphatases could also exhibit such a phospho-transferase activity with different acceptor molecules. Our research project is aimed at the complete functional and structural characterisation of these multiple membrane phosphatases.

**1MDa CELL DIVISION PROTEIN COMPLEX IN ESCHERICHIA COLI AS REVEALED BY NATIVE PAGE**

E. Trip<sup>1</sup>, D.J. Scheffers<sup>1</sup>

<sup>1</sup>Molecular Microbiology, GBB, Groningen, Netherlands

**Background**

Bacterial cell division is carried out at mid-cell position by a group of cell division proteins referred to as the divisome. For the Gram-negative model bacterium *Escherichia coli*; ten of these proteins (FtsZ, -A, -K, -B, -L, -N, -Q, -I, -W and ZipA) are considered as the core players of division. Thus far, interaction networks between individual divisome proteins have been investigated extensively with use of various biochemical and genetic techniques and many interactions between cell division proteins have been found. Still, no oligomeric interactions have been demonstrated that show that the divisome is present as a large multi-protein machinery.

**Objectives**

To detect whether or not a complete 'divisome' assembly is present in the cell.

**Methods**

Clear Native gel Electrophoresis on mildly solubilized *E. coli* cells, followed by 2D Electrophoresis and Western Blotting.

**Conclusions**

We describe the finding of a large 1 MDa cell division protein complex in *E. coli*, that includes at least 8 essential division proteins; FtsZ, ZipA, FtsK, FtsQ, FtsB, FtsL, and FtsN. The complex is present in cultures of rapidly dividing cells, but not when cells are not dividing. Also, we found that a slight overexpression of *ftsQ D237N* (encoding interaction-impaired FtsQ), prevents formation of this 1 MDa complex. Combined, our findings indicate that a large protein complex containing cell division proteins indeed exists.

**GAMMA-GLUTAMYLTRANSPEPTIDASE EXPRESSION IN CAMPYLOBACTER JEJUNI IS NOT ONLY REGULATED BY THE RACRS TWO-COMPONENT SYSTEM**

A. van der Stel<sup>1</sup>, P. Laniewski<sup>2</sup>, A. van Mourik<sup>1</sup>, J.P.M. van Putten<sup>1</sup>, E.K. Jagusztyn-Krynicka<sup>2</sup>, M.M.S.M. Wösten<sup>1</sup>

<sup>1</sup>Infection and Immunity, Utrecht University, Utrecht, Netherlands

<sup>2</sup>Dep of bacterial genetics, University of Warsaw, Warsaw, Poland

**Background**

*Campylobacter jejuni* is an asaccharolytic human pathogenic Gram-negative bacterium that utilizes amino acids as carbon and energy source and colonizes the gastrointestinal tracts of warm-blooded animals. Some strains of *C. jejuni* possesses the enzyme gamma-glutamyltranspeptidase (GGT), which enables growth on glutathione and glutamine by generation of glutamate in the periplasm and contributes to persistent colonization of the avian gut.

**Objectives**

We have shown that the RacRS two-component system is involved in cytoplasmic glutamate anabolism by regulating the *gltBD* genes, here we investigated whether the RacRS system also regulates the periplasmic glutamate anabolism by regulating the *ggt* gene.

**Methods**

Our results show that RacRS regulates the expression of *ggt* under low oxygen conditions. Under these conditions, higher transcription levels of the *ggt* gene and enhanced GGT activity are observed in the wt compared to the *racR* mutant strain. By using different *ggt* truncated promoter elements in EMSA and luciferase reporter assays we show that RacR binds directly on a specific location of the *ggt* promoter. Furthermore we show that under high oxygen conditions *ggt* expression peaks around end-log phase and GGT activity is highest in stationary phase and is not dependent on RacR. GGT expression and activity is repressed by addition of glutamine to the medium or glutamine catabolic products.

**Conclusions**

In conclusion we show that the *C. jejuni* GGT activity is dependent on multiple factors and one of them is the RacRS two-component system.

### **Background**

Antimicrobial peptides (AMPs) are natural antibiotics widespread throughout the animal kingdom, from bacteria to mammals. They are important components of both innate and adaptive immunity, providing protection against a broad-spectrum of pathogens, such as viruses, bacteria, fungi and parasites.

### **Objectives**

Investigate the effect of two human AMPs (HBD-3 and LL-37) on *Legionella pneumophila*

### **Methods**

In this study, we investigated the action of synthetic LL-37 and HBD-3 on both extracellular and intracellular lifestyle of *L. pneumophila*.

### **Conclusions**

We showed that both peptides exhibit a phase dependent bactericidal effect on extracellular *L. pneumophila*. We also observed that LL-37 and HBD3 inhibit intracellular replication of *L. pneumophila* in macrophages and pneumocytes. We showed by colony counting assays that the adherence and internalization of *L. pneumophila* was not affected in presence of LL-37, but was stimulated with HBD-3, suggesting that these two peptides restrain the bacterial replication by different mechanisms of action.

Human AMPs LL-37 and HBD-3 seem to be involved in innate immunity against *L. pneumophila* by acting on the extracellular bacteria and on its intracellular replication.

<sup>3</sup>*Molecular Cell Biology, VU University, Amsterdam, Netherlands*

<sup>4</sup>*Physics and Astronomy, VU University, Amsterdam, Netherlands*

**Background**

Membrane proteins perform vital cellular functions like respiration, signaling and nutrient uptake. For proper functioning, conformational dynamics, complex formation and ability to diffuse in the membrane are vital parameters. Despite a lot of work on model membranes, little is known about lateral mobility of proteins in bacteria.

**Objectives**

To investigate how molecular crowding, protein size and membrane fluidity affect the mobility of membrane proteins in living *E. coli* bacteria

Fig. 1. (A) Schematic diagram of expression construct for the production of cytoplasmic fluorescent protein (FP). fluorescent protein (eGFP) is represented in green, orange indicates peptide transport protein (CstA). Arrow points to the site of leader peptidase processing. RBS, ribosome-binding site. The asterisk indicates a stop codon. (B) Schematic diagram of expression construct for the production of periplasmic exported fluorescent protein (FP). Signal peptide (SS) used to export is represented in black, gray represents the linker (L), blue indicates fluorescent protein (sfGFP), red indicates mechanosensitive channel protein of small conductance (MscS). Arrow points to the site of leader peptidase processing. RBS, ribosome-binding site. The asterisk indicates a stop codon. (C) Schematic representation of a biological membrane, consisting of seven *E. coli* trans-membrane proteins embedded in phospholipids. (D) Time-laps images of single ssDsbA-sfGFP-MscS transmembrane protein tracked in the inner membrane of an *E. coli* cell (scale bar: 1  $\mu$ m)

## Methods

Here we use single-molecule wide-field epi-fluorescence microscopy to track the

lateral mobility of seven integral membrane proteins of different size fused to green fluorescent protein in living *E. coli*. We apply a novel method, IPODD to extract accurate diffusion coefficients from the 2-D projected diffusion trajectories along the 3-D curved bacterial membrane

### **Conclusions**

The diffusion coefficients we find are significantly lower than those reported in *in vitro* studies of isolated membrane proteins in GUVs. Our results indicate that molecular crowding in the plasma membrane of *E. coli* substantially slows down trans-membrane protein diffusion. Surprisingly, all seven proteins studied diffuse heterogeneously: they all show a faster and a slower moving component. Our interpretation of the heterogeneity is that it reflects heterogeneity in membrane composition. To further support this interpretation, we stained *E. coli* inner membrane with a lipid-mimicking dye Dil-C12 and tracked its lateral mobility. Strikingly, Dil-C12 diffuses heterogeneously yet again reflecting the dynamic heterogeneous nature of the plasma membrane. Therefore, from these observations, we propose that the plasma membrane of *E. coli* might contain micro-domains with different fluidity that could play key roles in specific localization of proteins.

<sup>4</sup>site La Chaux-de-Fonds, ADMED Laboratories, La Chaux-de-Fonds, Switzerland

<sup>5</sup>Bioscience Division, Los Alamos National Laboratory, Los Alamos New Mexico, USA

**Background**

Spore or spore-like structures are only found in four bacterial phyla: Actinobacteria, Cyanobacteria, Proteobacteria and Firmicutes. These structures provide resistance to adverse conditions. The ability to form spores is not, however, a widely spread characteristic and it is restricted to only some orders within those phyla. For example amongst Proteobacteria, solely  $\delta$ -proteobacteria can produce spore-like fruiting bodies, or so we knew. A novel  $\gamma$ -proteobacterium, *Serratia ureilytica* str. Lr5/4, was found to produce spores that not only resemble structurally to those produced by endospore-forming Firmicutes, but also provide heat-resistance.

**Objectives**

The aim of this study is to describe this novel strain and its Firmicute-like spores and to reveal the molecular pathway of this sporulation procedure in comparison to those that are already known.

**Methods**

Physiological, biochemical, carbon source assimilation and antibiotic resistance tests were performed. Morphology of vegetative cells and spores was described by phase contrast microscopy, SEM, and TEM. Moreover, spores of Lr5/4 were revived after heat-shock tests and shown to contain dipicolinic acid (DPA). These two characteristics were so far unique to the heat-resistant endospores found in Firmicutes. Sequencing and annotation of its full genome has been performed in order to reveal the relationship of spore formation in Lr5/4 to other known sporulation pathways.

**Conclusions**

It has been previously proposed that the properties of spore formation in non-sporulating species were due to molecular gene transfer. However, the present study rejects this scenario and demonstrates a novel mechanism for the formation of the described spores of *S. ureilytica*.

**FEMS-1489**

**BACILLUS SUBTILIS BIOFILMS INCREASE GUT COLONIZATION AND LIFESPAN IN THE ANIMAL MODEL CAENORHABDITIS ELEGANS**

R. Grau<sup>1</sup>, V. Donato<sup>1</sup>

<sup>1</sup>Microbiology, Universidad Nacional de Rosario - CONICET, Rosario, Argentina

**Background**

Biofilm proficiency has a great impact in bacteria-host interactions. *Caenorhabditis elegans* and the spore-forming bacteria *Bacillus subtilis* are both common soil inhabitants which are used as models of lifespan studies. However, the role of *in vivo* biofilm development during gut colonization and its effects on animal lifespan are poorly documented.

**Objectives**

Here, we investigated the ability of *B. subtilis* to form a biofilm in the intestine of *C. elegans* and its effects on gut colonization and lifespan of the nematode.

**Methods**

The results showed that wild-type NCIB3610 strain was able to colonize and persist in the gut of *C. elegans* more efficiently than the laboratory strain JH642. The ability to make a biofilm was essential for the observed behavior because FICT-labelled NCIB3610-derived biofilm-mutant cells, but not FICT-wild -type cells, lost the capacity to persist and colonize the nematode gut. *In situ fluorescence microscopy* and beta-galactosidase expression, driven from the promoter of surfactin harbored by *B. subtilis* engineered cells and used to feed the worm confirm the higher ability of NCIB3610, instead of JH642 cells, to colonize the gut of *C. elegans*. The ability to make a persistent biofilm correlated well with a positive lifespan effect of the bacterium on the nematode.

**Conclusions**

*B. subtilis* spores are able to germinate, growth, make biofilma and persist in the intestine of *C. elegans*. In addition, we provide evidences showing that the intestinal life cycle of *B. subtilis* making a biofilm is beneficial and required for the increase for the lifespan of *C. elegans*.

**Bacterial spores**

**CHARACTERIZATION OF SPORE-FORMING BACILLUS, ISOLATED FROM THE ANDES MOUNTAINS, EXHIBITING HIGH LEVELS OF RESISTANCE TO ARSENIC AND UV RADIATION**

R. Grau<sup>1</sup>, M. Bartolini<sup>1</sup>, C. Leñini<sup>1</sup>, D. Toniet<sup>2</sup>, M. Farías<sup>2</sup>

<sup>1</sup>Microbiology, Universidad Nacional de Rosario - CONICET, Rosario, Argentina

<sup>2</sup>Microbiology, PROIMI - CONICET, Tucuman, Argentina

**Background**

The North-Western part of Argentina is particularly rich in wetlands located in the Puna at an altitude between 3,600 and 4,600 m above sea level. Here, incidence of high levels of UV radiation and contamination with high contents of toxic metals, particularly arsenic (As) is common. We hypothesize that one strategy to contribute to the remediation of these area could be the use of *Bacillus* spp.

**Objectives**

We collected soil and water samples from different parts of the Puna and isolated native spore-forming Bacilli. The novel isolates were examined at different growth temperatures and osmolarities on their ability to grow and make biofilms in the presence of toxic concentrations of As and high UV radiation.

**Methods**

The Bacilli communities were characterized by pyrosequencing 16S rRNA gene amplicons derived from specific PCR oligonucleotides. The Andean *Bacillus* isolates displayed a greater capacity to make persistant biofilms, colonize surfaces (swarming motility) and tolerance to high temperatures, salinity and UV-B / UV-C radiations at levels that were lethal to common laboratory strains.

**Conclusions**

The present results allow the potential biotechnological application of the isolated *Bacillus* strains with bioremediation potential of pristine environments contaminated with metals.

## **NOVEL GENES INFLUENCING THE GERMINATION RATE OF SPORES OF BACILLUS SUBTILIS FOOD ISOLATES**

A.O. Krawczyk<sup>1</sup>, E.M. Berendsen<sup>1</sup>, A. de Jong<sup>1</sup>, J. Boekhorst<sup>2</sup>, R.T. Eijlander<sup>1</sup>,  
M.H. Wells-Bennik<sup>3</sup>, O.P. Kuipers<sup>1</sup>

<sup>1</sup>Molecular Genetics, University of Groningen, Groningen, Netherlands

<sup>2</sup>, NIZO Food Research, Ede-Wageningen, Netherlands

<sup>3</sup>, TI Food and Nutrition, Wageningen, Netherlands

### **Background**

*Bacillus subtilis* responds to starvation with formation of endospores. Spores can easily contaminate food materials and their resistance impedes their removal from food products. In response to various triggers, spores reinitiate vegetative growth via germination. Vegetative cells can subsequently cause food spoilage. Accurate prediction of germination behavior is difficult as differences in germination responses are observed even among various strains of one species. Thus, data obtained for the model strain, *B. subtilis* 168, cannot be directly applied to food-spoiling strains.

### **Objectives**

The purpose of this study was to elucidate germination behavior of spores of *B. subtilis* strains that cause food spoilage and to couple the observed germination phenotypes with the strains' genomic contents.

### **Methods**

Genomes of thirteen *B. subtilis* industrial isolates were sequenced. Germination of their spores was induced under various conditions and analyzed via absorbance measurements and phase-contrast microscopy. The spore germination responses of different strains were linked with their genomic content using gene-trait matching software.

### **Conclusions**

Strains were divided into two phenotypic groups based on the ability of their spores to germinate, in particular their germination rates. Slower germination correlated with the presence of specific genes in industrial isolates, which are absent in the laboratory strain *B. subtilis* 168. Insertion of these genes into *B. subtilis* 168 decreased the rate of germination of its spores. Thus, new genes influencing *B. subtilis* germination responses were identified. The function of these genes is currently being elucidated. These genes can be used in the future as biomarkers indicating slow germination.

## **UNDERSTANDING BACTERIAL SPORE RESISTANCE TOWARDS PLASMA STERILIZATION**

M. Raguse<sup>1</sup>, M. Fiebrandt<sup>2</sup>, B. Denis<sup>2</sup>, K. Stapelmann<sup>2</sup>, P. Awakowicz<sup>2</sup>, G. Reitz<sup>1</sup>,  
R. Moeller<sup>1</sup>

<sup>1</sup>Radiation Biology, German Aerospace Center, Köln, Germany

<sup>2</sup>Institute for Electrical Engineering and Plasma Technology, Ruhr University Bochum, Bochum, Germany

### **Background**

Background: Spores of *Bacillus subtilis* have been used extensively as biological indicators for industrial purposes such as sterilization or decontamination. For several years a number of activities in the field of sterilization of heat sensitive materials by means of non-thermal plasmas have been known. Plasma sterilization methods are characterized by the use of gas or gas mixtures that are partially excited by an applied electric field. Plasma discharges contain a high degree of UV/VUV-radiation, as well as charged particles and free radicals, which exert detrimental effects on microorganisms by damaging genetic material, outer cell layers and proteins.

### **Objectives**

Objectives: We are interested in understanding the protective attributes and molecular mechanisms involved in the *B. subtilis* spore resistance to plasma sterilization.

### **Methods**

Methods: In a systematic manner different *B. subtilis* spores varying in their protection (e.g., coat, crust, DPA, SASP formation) and DNA repair capabilities were studied on their impact towards plasma sterilization.

### **Conclusions**

Conclusions: We will present our recent findings on the protective attributes and molecular mechanisms involved in the spore resistance to plasma sterilization. The multi-layered proteinaceous spore coat, being the first barrier to environmental influences, was shown to be a major factor contributing to spore resistance towards plasma treatment. During spore revitalization, DNA damage accumulated during the dormant spore stage is the subject of a variety of different repair systems. Deficiencies in repair genes of non-homologous end-joining, spore photoproduct

lyase, or nucleotide excision repair led to a significant decrease in spore resistance to low pressure plasma sterilization.

**Bacterial spores**

**SPORULATION TEMPERATURE HAS LIMITED EFFECT ON THE SPORE PROTEOME OF BACILLUS WEIHENSTEPHANENSIS.**

S.K. Stelder<sup>1</sup>, H.L. Dekker<sup>2</sup>, L.J. de Koning<sup>2</sup>, C.G. de Koster<sup>2</sup>, S. Brul<sup>1</sup>

<sup>1</sup>*Molecular Biology and Microbial Food Safety, University of Amsterdam, Amsterdam, Netherlands*

<sup>2</sup>*Mass Spectrometry for Biomacromolecules, University of Amsterdam, Amsterdam, Netherlands*

**Background**

*Bacillus weihenstephanensis* is a spore forming food pathogen known for its ability to sporulate, germinate, grow and produce toxins at lower temperatures than its close relatives. As such, it presents an increased risk to food safety where standard procedures rely on cold-inactivation of microbes. Properties of the infective form Bacilli, the spore, are known to vary with the conditions under which the spores were produced. For instance, lower sporulation temperature has been indicated to result in a lower wet heat resistance. This resistance is in part attributed to the spore coat layers, proteinaceous layers surrounding the core which contains the bacterial DNA.

**Objectives**

The aim of this study was to determine the proteomic basis for the heat resistant phenotype. As no specific singular protein can be indicated to confer heat resistance, this supposedly acquired trait can only be appreciated by analysis of the spore proteome as a whole.

**Methods**

Analysis of the proteome of spores of *B. weihenstephanensis* strain WSBC10204 produced at either 12°C or 30°C by mass spectrometry provided insight into variations in the protein content of the spore coat at different sporulation temperatures.

**Conclusions**

Interestingly, only minor differences were observed, suggesting wet heat resistance does not depend on the identity of the proteins making up the coat layers. As wet heat resistance was indeed lower for the spores produced at lower temperatures, low temperature might instead affect the rate of spore maturation instead, a process where spore coat proteins are cross-linked after they have been deposited onto the spore.

<sup>2</sup>IMIT/Organismic Interactions, University of Tübingen, Tübingen, Germany

<sup>3</sup>OSUR, Université de Rennes 1, Rennes, France

<sup>4</sup>UMR CNRS 6553 ECOBIO, Université de Rennes 1, Rennes, France

**Background**

Akinetes are resting cells of species members of the Nostocales and Stigonematales orders of cyanobacteria. These are spore-like, non-motile cells that differentiate from vegetative cells and serve a perennating role. During their differentiation, akinetes varies their metabolic activities and cellular pools.

**Objectives**

Here we follow carbon assimilation in the cyanobacterium *Aphanizomeno ovalisporum* and accumulation of cyanophycin during akinetes differentiation and maturation.

**Methods**

Photosynthetic assimilation of  $\text{H}^{13}\text{CO}_3^-$  was studied by NanoSIMS technology and variations in abundance and distribution of cyanophycin globules were followed by transmission electron microscopy and histochemistry techniques.

**Conclusions**

NanoSIMS results clearly indicate that during their differentiation, akinetes maintain metabolic activity and assimilate inorganic carbon via photosynthesis. Towards advanced stages of differentiation and maturation, the metabolic activity of akinetes reduced and many of the free akinetes lost their photosynthetic capacity as indicated by changes in  $^{13}\text{C}/^{12}\text{C}$  ratio. Nevertheless, a small group of free (mature akinetes) still maintains their photosynthetic capacity. Structural changes during akinetes differentiation observed by transmission electron microscopy and histochemistry techniques, included the accumulation of cyanophycin bodies in akinetes. The rate of cyanophycin accumulation and carbon allocation into this protein storage is currently being investigated in a complementary NanoSIMS analysis.

**THE ESSENTIALS OF LIFE; PROTEOMICS OF DORMANT AND AWAKENING SPORES OF BACILLUS SUBTILIS**

B. Swarge<sup>1</sup>, H. Dekker<sup>1</sup>, L. de Koning<sup>1</sup>, S. Brul<sup>1</sup>, C. de Koster<sup>1</sup>

<sup>1</sup>SILS, University of Amsterdam, Amsterdam, Netherlands

**Background**

In response to nutrient limitation Gram positive organisms like *Bacillus subtilis* form dormant spores. These cellular entities are survival capsules, resistant to chemical and environmental assaults. They pose challenges to the food and medical sectors. Upon contact with germinants spores return to vegetative life through a process called 'germination and outgrowth'. The vegetative cells may cause food spoilage and food borne diseases.

**Objectives**

To perform a detailed quantitative time-resolved proteomics study of (dormant)spores and their secretome during germination and outgrowth

**Methods**

Using a quantitative proteomics approach a study of the time resolved break down of spore proteins during early stages of germination was initiated. Spores were germinated in minimal medium supplemented with a germinant mixture (L-Asparagine, D-glucose D-fructose and Potassium Chloride). The spore layers and the secretome were analyzed separately by Ion Trap LC-MS/MS analysis

**Conclusions**

During germination the action of proteases, lytic enzymes and peptidases in the spore results in proteolysis, cortex hydrolysis and break down of spore dormancy. Partially digested proteins as well as intact proteins are released from the spore in to the medium. Study of these proteins by our method allowed us to understand molecular details of the germination process. Current analyses are aimed at correlating the germinating spore proteome to its transcriptome under control as well as thermal and organic acid stress conditions (Keijser et al. 2007 and Ter Beek et al., our unpublished observations). We aim at deconvoluting heterogeneous germination and outgrowth profiles using our live imaging technology (Pandey et al., 2013).

#### **STRAIN DIVERSITY ALONG THE LIFE CYCLE OF BACILLUS CEREUS**

A. Warda<sup>1</sup>, Y. Xiao<sup>1</sup>, M. Wells-Bennik<sup>2</sup>, M. Nierop Groot<sup>3</sup>, T. Abee<sup>1</sup>

<sup>1</sup>Laboratory of Food Microbiology, Wageningen University and Reserch Center, Wageningen, Netherlands

<sup>2</sup>TIFN, TI Food and Nutrition, Wageningen, Netherlands

<sup>3</sup>Food and Biobased Research, Wageningen University and Reserch Center, Wageningen, Netherlands

#### **Background**

Undomesticated spore formers isolated from the environment or from processing facilities commonly show higher diversity, resistance and more heterogeneous behaviour compared to widely used reference strains domesticated in laboratories and that may have lost relevant traits. Analysis of such undomesticated isolates therefore provides valuable insights in sporulation capacity, spore resistance, germination and outgrowth efficiency that determine survival and fitness in different environmental niches including food and food processing environments.

#### **Objectives**

In our project we aim to obtain insight in the diversity among pathogenic *Bacillus cereus* strains with focus on spore properties. To this end, *B. cereus* reference strains ATCC14579 and ATCC10987 were analysed and compared to behaviour of strains isolated from food and food production facilities.

#### **Methods**

Growth, sporulation and germination capacity of 20 *B. cereus* strains isolated from different food products and two reference strains was characterized under different conditions. Spore stress resistance and germination characteristics were assessed upon exposure to disinfectants, heat and mild processing technologies. Behaviour of untreated and treated spores was analysed both at population level as well as at the level of individual spores by using Flow cytometry (FCM) in combination with sorting (FACS).

#### **Conclusions**

The *B. cereus* strains displayed a highly diverse response with respect to growth, sporulation, spore resistance and germination capacity. Additionally, spore population behaviour showed substantial differences with some strains displaying a

homogenous and other a heterogeneous performance. We have demonstrated the relevance of including environmental isolates in the studying behaviour of pathogenic spore former *B. cereus* along the different steps of life cycle.

## FEMS-2565

### Bacterial spores

#### INSIGHT IN HEAT INACTIVATION AND GERMINATION BEHAVIOR OF HEAT RESISTANT SPORES OF BACILLUS LICHENIFORMIS, B. AMYLOLIQUEFACIENS AND B. THERMOAMYLOVORANS

E.M. Berendsen<sup>1</sup>, A.O. Krawczyk<sup>2</sup>, R.T. Eijlander<sup>2</sup>, O.P. Kuipers<sup>3</sup>, M.H.J. Wells-Bennik<sup>4</sup>

<sup>1</sup>NIZO food research and University of Groningen, Top Institute Food and Nutrition, Ede, Netherlands

<sup>2</sup>University of Groningen, Top Institute Food and Nutrition, Groningen, Netherlands

<sup>3</sup>Laboratory of Molecular Genetics, University of Groningen, Groningen, Netherlands

<sup>4</sup>NIZO Food Research, Top Institute Food and Nutrition, Ede, Netherlands

### Background

*Bacillus licheniformis*, *B. amyloliquefaciens* and *B. thermoamylovorans* can cause significant non-sterility issues in high heat treated foods due to survival of heat resistant spores that can subsequently germinate followed by outgrowth during the shelf life.

### Objectives

To gain improved control of spores of these species in food manufacturing, a genetic basis for spore heat resistance and germination efficiency was investigated by combining spore phenotypes and genome information of individual strains.

### Methods

The heat inactivation kinetics of spores of different isolates were determined. In addition, the genomes of over 20 strains within these species were sequenced to investigate a genetic basis for different spore heat resistances.

For *B. licheniformis* (10 strains) and *B. amyloliquefaciens* (9 strains) significant differences in heat resistance of spores were found for different isolates. Strains producing heat resistant spores contained a subset of genes belonging to a cluster that confers high heat resistance in *B. subtilis*.

For spores of *B. thermoamylovorans* (4 strains) spore heat resistance, nutrient germination, non-nutrient germination, and detailed spore counts were determined. Non-nutrient germination using calcium-dipicolinic acid induced good germination of spores of all strains. Poor germination on regular rich cultivation media resulted in gross underestimation of the viable spores truly present.

## **Conclusions**

The above findings shed light on different phenomena that can contribute to spore survival. Such information is important to devise appropriate strategies to enumerate spores in food ingredients and to inactivate spores, leading to improved control of heat resistant spores in foods.

**Bacterial spores**

**SSGB COORDINATES SEPTUM SITE LOCALIZATION WITH CHROMOSOME ORGANIZATION DURING STREPTOMYCES SPORULATION**

*J. willemse<sup>1</sup>, H. van der heul<sup>1</sup>, J. Mulder<sup>1</sup>, R. Pannu<sup>2</sup>, B. Koster<sup>3</sup>, D. Claessen<sup>1</sup>, G.P. van Wezel<sup>1</sup>*

<sup>1</sup>*MBT, Leiden University, LEIDEN, Netherlands*

<sup>2</sup>*BSC, Leiden University, LEIDEN, Netherlands*

<sup>3</sup>*MCB-EM, LUMC, LEIDEN, Netherlands*

**Background**

Streptomyces are multicellular bacteria with a complex life cycle. During the reproductive phase aerial hyphae transition into chains of hundred or more spores via a highly orchestrated cell division process. Coordination of sporulation is regulated by the SALP proteins (SsgA-like proteins). SsgA forms an array of foci along the hypha and provides an anchor for SsgB to multimerize on the cell membrane, after which SsgB recruits FtsZ and stimulates FtsZ polymer formation.

**Objectives**

SsgB is a highly conserved protein that forms trimers. The C-terminal  $\alpha 3$  helix is important for trimerization and interacts with  $\alpha 1$  and  $\alpha 2$  of the neighboring SsgB monomers. To elucidate how SsgB interacts with SsgA and FtsZ, we have created an SsgB mutant library.

**Methods**

These ssgB variants were introduced in the ssgB mutant strain, after which strains were automatically scored for restored sporulation via a scanner based imaging approach. Over 500 variant SsgB a single amino acid change and these were further analysed.

**Conclusions**

All sporulating samples were examined with transmission electron microscopy (TEM), which revealed effects varying from changes in spore wall thickness, size distribution, DNA segregation to affecting spore shape. In contrast wild type spores are similar sized, have condensed DNA in the center of the spores and have a thick spore wall.

We have shown that single amino acid changes in SsgB can facilitate many division related phenotypes. and ultimately dictate septum orientation resulting in longitudinal division. The latest results in elucidating the function of individual amino acids will be presented.

**Biofilms**

**EVALUATION OF TWO SCREENING METHODS FOR DETECTION OF BIOFILM FORMATION AND ITS EFFECT ON ANTIBIOTIC SUSCEPTIBILITY AMONG STAPHYLOCOCCI SPECIES**

O. Aboulola<sup>1</sup>, M. Mansour<sup>1</sup>, S. Elazab<sup>1</sup>, S. El-Hadidy<sup>1</sup>

<sup>1</sup>*Microbiology and Immunology, Faculty of Medicine Suez Canal University, Ismailia, Egypt*

**Background**

Biofilm formation is a hallmark characteristic of staphylococcal infections as it allows attachment to solid surfaces, exchange of genes that can result in more virulent strains, production of high concentration of toxins, evasion of immune defenses and antimicrobial resistance.

**Objectives**

This study was conducted to evaluate two different screening methods for detection of Biofilm formation and its effect on antibiotic susceptibility among the clinical isolates of different Staphylococci species.

**Methods**

**Seventy five isolates of staphylococci were tested by modified tissue culture plate method (MTCP), congo red agar (CRA) method and tube method (TM) for their ability to form biofilm. Antibiotic susceptibility testing was done for thirty isolates, 15 biofilm-producers and 15 biofilm nonproducers, using broth microdilution assay.**

**Conclusions**

The rate of detection of biofilm formation among the staphylococcal isolates by the MTCP method, the CRA method and the TM were 48%, 38.7% and 25.3% respectively. Comparing to the results of MTCP method as a gold standard, the sensitivities of the CRA method and tube method were 80.6% and 52.8% respectively. Both showed 100% specificity. Regarding the antibiotic susceptibility of the biofilm producers and non-producers, statistically significant differences were detected for oxacillin, ceftriaxone and augmentin susceptibility ( $P < 0.02$ ). All the

isolates were sensitive to vancomycin. The MTCP takes 3 days and many steps. The TM is observer dependent. Congo red agar method can be used as a screening method for detection of biofilm formation among staphylococcal isolates as it is cheap, rapid with no subjective errors and requires less expertise.

<sup>4</sup>*Centro de Citricultura Sylvio Moreira, Instituto Agronômico, Cordeirópolis, Brazil*

<sup>5</sup>*University of Oulu, Microelectronics and Material Physics Laboratories, Oulu, Finland*

**Background**

*Xylella fastidiosa* (*Xf*) affects plant xylem vessels, causing diseases such as Pierce's disease. As abundant plants of economic relevance may be affected by *Xf*, it is essential understanding the biofilm formation behavior of *Xf*, whose genome has been sequenced partly by our collaborators for developing appropriate countermeasures.<sup>[1]</sup>

**Objectives**

The appearance of *Xf* infected olive trees in Italy is of substantial concern due to the first appearance of this species within Europe. Considering the role of biofilms within many human diseases, the investigation of the adsorption behavior of bacteria along with the involved biomolecules is evident.<sup>[2][3]</sup> Particularly interesting is the formation

of disulfide bonds appearing essential during biofilm formation.<sup>[4]</sup>

### Methods

This study focuses on the analysis of biomolecules involved in *Xf* biofilm formation via vibrational spectroscopy. In a unique instrumental combination, infrared attenuated total reflection (IR-ATR) spectroscopy and atomic force microscopy (AFM) were applied to characterize the growth media and biofilms associated with *Xf*.

### Conclusions

Experimental and analytical procedures will be discussed providing first insight on the involved molecular processes during biofilm formation and maturation.

## **SUPPLEMENTARY MICROBIOLOGICAL ANALYSIS OF FILLING MATERIALS REVEALS NEW INSIGHT INTO THE ECOLOGY OF PERSISTENT ENDODONTIC INFECTIONS**

A. Al-Ahmad<sup>1</sup>, L. Karygianni<sup>1</sup>, C. Tennert<sup>1</sup>, M.J. Altenburger<sup>1</sup>, E. Hellwig<sup>1</sup>,  
A. Anderson<sup>1</sup>

<sup>1</sup>Operative Dentistry and Periodontology, Albert-Ludwigs-University Freiburg,  
Freiburg, Germany

### **Background**

Persistent root canal infections correlate with endodontic treatment failures. Microorganisms have been found in 35%-100% of previously treated root canals. The analysis of the microbiota of endodontic infections is prerequisite for improvement of treatment methods of infected root canals.

### **Objectives**

1. The microbiological analysis of infected root-filled teeth with periradicular lesions using culture-dependent and -independent approaches
2. The analysis of the microorganisms adhered to the retrieved endodontic filling materials (EFM) and the comparison with the results gained from the root canal samples alone.

### **Methods**

Twenty patients were enrolled in this study and samples from the corresponding twenty root-filled teeth were taken according to standard protocols. In addition to these samples, the EFM were also analyzed microbiologically using culture and culture-independent methods and transmission electron microscopy. The culture-independent technique was conducted by cloning and sequencing of 16S rRNA amplicons.

### **Conclusions**

**Results:** Bacteria were revealed in 15 root canal samples and in 18 EFM samples at a concentration ranging from  $10^3$  to  $10^7$  cfu/ml. 56 different species were found in association with the root canal filling materials. In contrary, only 47 species could be identified in the root canal samples. 20 species were detected solely in the EFM samples including *Aggregatibacter actinomycetemcomitans* and *Eubacterium nodatum*. The most abundant species belonged to the phyla Firmicutes, Actinobacteria and Proteobacteria.

**Conclusions:** The analysis of microorganisms associated with root-canal filling materials in addition to the root canal samples taken after revision reveals a better insight into endodontic infections and should not be neglected.

## **Biofilms**

### **ANALYSIS OF INTERACTIONS BETWEEN NEISSERIA STRAINS IN BIOFILMS**

A. Rodriguez<sup>1</sup>, J. Tommassen<sup>1</sup>, J. Arenas<sup>1</sup>

<sup>1</sup>Molecular Microbiology, Microbiology, Utrecht, Netherlands

#### **Background**

The human nasopharynx is colonized by different species of the genus *Neisseria*, including commensals, such as *N. lactamica*, but also an important pathogen, i.e. *N. meningitidis*. In situ, these bacteria are organized in micro-colonies, structures that resemble biofilms and that may represent a defense mechanism for the bacteria to survive in a hostile environment. In vivo, these species must interact and compete for the same niche.

#### **Objectives**

Here, we designed novel constructs to generate green and red fluorescent *Neisseria* strains to facilitate the discrimination between different microorganisms by microscopy in several assays.

#### **Methods**

These constructs were stably integrated in a highly conserved region on the chromosome of both species, as evidenced PCR assays, and allowed for constitutive expression of the fluorescent proteins. We next optimized biofilm formation assays and studied the organization of biofilms of independent and mixed *Neisseria* strains.

#### **Conclusions**

Our results showed that indeed biofilms of monocultures of *N. meningitidis* and *N. lactamica* are organized as micro-colonies with intervenient spaces. However, the organization of these spaces and the distribution of the biomass varied between strains of the same species. Mixed biofilm assays revealed that both species can differently interact, altering the organization of the biofilms. This work is the first report of the interaction between both species and allows for speculation about the process of human colonization.

## **CHANGES IN SEWER BIOFILM MICROBIAL COMMUNITIES RELATED TO DOWNSTREAM NITRATE DOSAGE**

O. Auguet<sup>1</sup>, M. Pijuan<sup>1</sup>, H. Guasch-Balcells<sup>1</sup>, C.M. Borrego<sup>2</sup>, O. Gutierrez<sup>1</sup>

<sup>1</sup>*Technologies and evaluation, Catalan Institute for Water Research, Girona, Spain*

<sup>2</sup>*Water Quality, Catalan Institute for Water Research, Girona, Spain*

### **Background**

Nitrate ( $\text{NO}_3^-$ ) is an effective and widely used chemical in sewer systems to reduce biogenic sulfide ( $\text{H}_2\text{S}$ ) and methane ( $\text{CH}_4$ ) produced in anaerobic rising main pipes. However, the main limitation of this approach is that anoxic conditions must be continuously kept through the whole pipe, otherwise  $\text{H}_2\text{S}$ -producing biofilms prevail.

### **Objectives**

The aim of this study is to determine the effects of the Downstream Nitrate Dosage strategy (DND) on anaerobic sewer biofilms with regards to sulfide oxidation and, for the first time, on methane production.

### **Methods**

Effectiveness of the strategy was assessed on  $\text{H}_2\text{S}$  and  $\text{CH}_4$  abatement on the effluent of specially designed laboratory-scale systems that mimics a real sewer biofilms. A combination of process (normal functioning monitoring and batch tests) and molecular (by 454-pyrosequencing) methods were used to investigate the impacts and microbial activities related to the nitrate addition.

### **Conclusions**

Results showed a complete abatement of  $\text{H}_2\text{S}$  generated, due to the growth of a Sulfide-Oxidizing Nitrate-Reducing population. Methane was reduced to 50% while nitrate was added, due to the  $\text{CH}_4$  oxidation in the anoxic conditions established at the end of the pipe. An increase of microorganisms of the genera *Simplicispira*, *Comamonas*, *Azonexus* and *Thauera* was detected during nitrate addition. Regarding anoxic methane oxidation, only one Operational Taxonomic Unit (OTU) was identified, which is likely related with this metabolism. Both sulfidogenic and methanogenic activities resumed upon cessation of  $\text{NO}_3^-$  dosage. Obtained results are relevant for the optimal management of nitrate dosage strategies in sewer systems.

**FEMS-1933**

**Biofilms**

## **CHANGES OF MICROBIAL COMMUNITIES DURING DIFFERENT STAGES OF BIOFILM DEVELOPMENT IN SEWER SYSTEMS**

O. Auguet<sup>1</sup>, M. Pijuan<sup>1</sup>, J. Batista<sup>1</sup>, C.M. Borrego<sup>2</sup>, O. Gutierrez<sup>1</sup>

<sup>1</sup>*Technologies and evaluation, Catalan Institute for Water Research, Girona, Spain*

<sup>2</sup>*Water Quality, Catalan Institute for Water Research, Girona, Spain*

### **Background**

Transport of wastewater along sewer pipes facilitates the formation of microbial biofilms that grow attached to their inner surfaces. Anoxic conditions in sewers favour the production of both sulfide (H<sub>2</sub>S) and methane (CH<sub>4</sub>) as end products of anaerobic microbial metabolisms, i.e. sulfate-reduction and methanogenesis, respectively. The build-up of H<sub>2</sub>S and CH<sub>4</sub> in sewerage causes different detrimental effects such as odour, corrosion and toxicity.

### **Objectives**

The aim of this study was to investigate the initial stages of development of microbial biofilms in sewer systems with a special focus on the interactions between sulfate-reducing bacteria (SRB) and methanogenic archaea (MA).

### **Methods**

The work was carried out using a laboratory sewer pilot plant fed with wastewater that mimic the functioning of a real anaerobic pressured sewer. Biological activities and phylogenetic community composition were investigated during sewer colonisation using a combination of molecular techniques (DGGE, qPCR and 16S rRNA tag sequencing) and process data (H<sub>2</sub>S and CH<sub>4</sub> production).

### **Conclusions**

Results showed that the SRB community was established and active after two weeks of biofilm development, causing substantial sulfide accumulation in the pilot plant. In turn, growth of MA and methane production were low during initial stages of biofilm colonisation but readily increased over time after the replacement of initial MA species derived from human faeces (*Methanobrevibacter* spp.) by other MA representatives more adapted to sewer conditions (*Methanosaeta* spp.). Altogether, our results pointed to different dynamics and activity of key community members from sewer biofilms, greatly affecting the production kinetics of H<sub>2</sub>S and CH<sub>4</sub> along time.

**LIPIDOMICS OF THE BIOFILM FORMED BY VIBRIO CHOLERAЕ N16961 UNDER INORGANIC PHOSPHATE LIMITATION IN THE PRESENCE OF BILE SALT**

L.C. Barbosa<sup>1</sup>, P. von Antwerpen<sup>2</sup>, J.M. Ruysschaert<sup>3</sup>, P.M. Bisch<sup>1</sup>,  
W.M.A. von Krüger<sup>1</sup>

<sup>1</sup>*Instituto de Biofísica Carlos Chagas Filho, Universidade Federal do Rio de Janeiro, Rio de Janeiro, Brazil*

<sup>2</sup>*Laboratory of Pharmaceutical Chemistry and Analytical Platform of the Faculty, Université Libre de Bruxelles, Brussels, Belgium*

<sup>3</sup>*Centre de Biologie Structurale et de Bioinformatique, Université Libre de Bruxelles, Brussels, Belgium*

**Background**

To better understand the molecular events that occur during *Vibrio cholerae* biofilm formation *in vivo*, we did a previous proteomic analysis of planktonic and biofilm cells, after 14, 24 and 48h of growth under conditions that mimic the intrainestinal environment, namely, pH 7.4 at 37°C, Pi limitation and the presence of the bile salt, sodium deoxycholate (DOC). The groups of differential proteins identified indicated that free cells were at stationary phase, whereas, those in biofilms were at exponential culture phase, after 48h growth. Moreover, in planktonic cells at all times, alkaline phosphatase was produced, suggesting Pho regulon activity, which was not observed in the biofilms cells.

**Objectives**

To perform a lipidomic analysis to explore differences in lipid profiles between planktonic and biofilm cells of *V. cholerae*.

**Methods**

Cells were grown overnight in MGLP (MOPS, salts, glucose, pH 7.4 with KH<sub>2</sub>PO<sub>4</sub> at 0.65μM-low phosphate) without (free cells) or with 0.2% DOC (biofilm) for 14-48hs, at 37°C, without agitation. The lipids were extracted according to Bligh and Dyer 1959 and analyzed by Q-TOF LC/MS.

**Conclusions**

In the 14h planktonic cells, the great majority of phospholipids was replaced by ornithine containing lipids (OL). Between 24 and 48h, OLs were found in these cells, but in smaller amounts. In biofilm cells, phosphatidylethanolamine (PE) was the major lipid at all times, whereas OLs were detected in small amounts. These data suggest, for the first time, the involvement of PhoB regulated genes in the expression regulation of OLs and PE in *V. cholerae*.

**ADHESION OF ENTEROCOCCUS FAECIUM ON PLASTIC AND STAINLESS STEEL AND ITS ANTI-ADHESIVE POTENTIAL TOWARDS PATHOGENS**

F. Bendali<sup>1</sup>, A. Ait Meddour<sup>1</sup>, D. Sadoun<sup>1</sup>

<sup>1</sup>Microbiology, A. Mira University, Bejaia, Algeria

**Background**

Bacteria have the ability to attach to surfaces commonly found in the food processing environment, such as polystyrene and stainless steel and to become more resistant to environmental stresses and sanitizers. So the search for new fight strategies is needed

**Objectives**

In this study, a strain of *Enterococcus* (*En.*) *faecium*, originally isolated from a milking machine inner-surface, was studied for its biofilm formation potential on plastic and stainless steel supports and its antibacterial and anti-adhesive potential against four pathogens (*Escherichia coli* ATCC 25922, *Staphylococcus aureus* ATCC 25923, *Pseudomonas aeruginosa* ATCC 27853 and *Listeria innocua* CLIP 74915).

**Methods**

The adhesion and the anti-adhesive potential of this strain were studied (at 25 and 37°C) using polystyrene microtiter plates and stainless steel 304 L coupons after their surface characterization by contact angle method.

**Conclusions**

The results revealed that the strain was a strong biofilm producer on polystyrene and stainless steel either at 25 and 37°C with the best adherence level observed at 25°C. *En. faecium* cells and culture supernatant showed a significant ( $p<0.05$ ) inhibition potential of the pathogens most probably due to bacteriocins synthesis.

**BIOFILMS X-TREME: TOLERANCE OF THE THERMOACIDOPHILIC ARCHAEON SULFOLOBUS ACIDOCALDARIUS TO 1-BUTANOL EXPOSURE**

J.C. Benninghoff<sup>1</sup>, J. Wingender<sup>2</sup>, B. Siebers<sup>1</sup>

<sup>1</sup>Biofilm Centre - Molecular Enzyme Technology and Biochemistry,  
University of Duisburg-Essen, Essen, Germany

<sup>2</sup>Biofilm Centre - Aquatic Microbiology, University of Duisburg-Essen, Essen,  
Germany

**Background**

Archaeal biofilms are interesting for biotechnological applications like whole cell biocatalysis, because they promise a higher tolerance towards toxic compounds, which is a characteristic property known for biofilms. In this study the effect of the organic solvent 1-butanol on biofilms of the thermoacidophilic, aerobic crenarchaeon *Sulfolobus acidocaldarius* with growth at 78 °C and pH 3 was investigated. *S. acidocaldarius* is adapted to extreme environments, genetically tractable and able to form biofilms.

**Objectives**

The aim of this study was to characterize the tolerance of *S. acidocaldarius* biofilms to 1-butanol exposure. The effect to 1-butanol on biofilm formation as well as on established biofilms was investigated.

**Methods**

Submerged biofilms were grown (4 d, 78 °C) in 96-well microtiter plates, Petri dishes or  $\mu$ -dishes on either polystyrene or glass surfaces. 1-butanol was present during biofilm formation or added to already established biofilms. Analysis of biofilms was performed by microscopic methods (confocal laser scanning microscopy, epifluorescence microscopy, atomic force microscopy, environmental scanning electron microscopy), and microbiological and biochemical methods (determination of total cell counts, viable counts and aerobic respiration activity). Extracellular polymeric substances were isolated and quantified by colorimetric assays.

**Conclusions**

*S. acidocaldarius* tolerates 1-butanol concentrations up to 1.5 % [v/v] as validated by viability assays. 1-butanol exposure led to stress responses like aggregation of cells, a change of carbohydrate distribution and composition as well as carbohydrate and

protein amounts in the biofilm matrix. Butanol-exposed biofilm cells revealed alterations of shape and loss of cell appendages.

**EFFECT OF THAI-PLANT EXTRACTS AND COMBINATION WITH ANTIBIOTICS  
ON PSEUDOMONAS AERUGINOSA BIOFILM FORMATION**

K. boonbumrung<sup>1</sup>, W. Chaicumpa<sup>2</sup>

<sup>1</sup>*Transfusion medicine and clinical microbiology, Chulalongkorn University, Bangkok, Thailand*

<sup>2</sup>*Department of Parasitology, Mahidol University, Bangkok, Thailand*

**Background**

*Pseudomonas aeruginosa* is the most common Gram-negative bacteria causing fatal nosocomial infections in hospitalized patients especially with the immunocompromised subjects. Bacteria can resist a wide variety of currently available antibiotics. One of resistant mechanisms is by forming the biofilm in infected host preventing drugs to access to the respective targets of the bacterial cell. Novel strategy to overcome this antibiotic resistant mechanism is to use the combination of antibiotics with inhibitors of biofilm formation.

**Objectives**

The objective in this study is to investigate the effect of mulberry-leaf, fruit and goji berry on biofilm formation from *P. aeruginosa*.

**Methods**

The result was shown by specific biofilm formation (SBF) index and the ethanolic extract (256 mg/ml) and the ether extract (32 mg/ml) of mulberry-leaf presented strong activity (SBF index > 1.1) to reduce biofilm in 44.0 % and 44.8 %, respectively. The plant extract with anti-biofilm activity was tested further in combination with gentamicin (0.125 to 1024 µg/dl) by Checkerboard method indicated that there was no synergistic efficacy. The results of MBEC and CLSM revealed that the ethanolic extract (32 mg/ml) was effective on *P. aeruginosa* biofilm.

**Conclusions**

The extract of mulberry-leaf could be an alternative thai herbs for biofilm formation inhibiting the most common drug resistant bacteria.

### **Background**

In natural and man-made ecosystems, anammox bacteria demonstrate a strong tendency for attached growth and biofilms formation.

### **Objectives**

We studied biofilms structure and formation by microbial community with dominant group of anammox bacteria, enriched in anaerobic vertical upflow bioreactor with nitrogen load 5 g N/l per day and upflow vertical concentration gradient of nitrogen substrates and pH.

### **Methods**

Biofilms structure and microbial community composition were studied via microscopy (light, electron, confocal and atomic force) and molecular genetics methods (sequencing and FISH). Biofilm formation *de novo* was studied on microscopic slides submerged in the upper part of the bioreactor.

### **Conclusions**

Several groups of microorganisms are involved in biofilm formation. Anammox bacteria belong to three different species. Their satellites are: trichal forms (presumably *Chloroflexi*), coccoid and rod-shaped cells (likely different species of nitrifier and denitrifier communities involved in nitrogen removal and trace amounts of oxygen consumption). *Chloroflexi* community includes 3 phylotypes of *Anaerolineae* and *Dehalococcoidia* strains responsible for biofilm spatial structure formation and trace amounts of organics elimination.

Primary biofilms are discovered on day 10-12. Subsequent growth of biofilms appears due to increasing the number of cells involved in biofilms and extracellular polymeric matrix accumulation. Mature biofilms (80-90 days) include cells of the same morphotypes as mature biofilms inside the reactor: clustered cocci with typical

anammox ultrastructure, interstitial rods and remarkably long trichal cells (more than 100  $\mu\text{m}$  long).

Surface microrelief images of such biofilms were obtained via atomic force microscopy.

**ASSESSMENT OF BIOFILM DESTABILIZATION AND REMOVAL BY LAUNDRY AGENTS**

B. Braun<sup>1</sup>, U. Szewzyk<sup>1</sup>

<sup>1</sup>*Environmental Microbiology, TU Berlin, Berlin, Germany*

**Background**

The formation of biofilms is a well known phenomenon in a variety of technical and natural environments such as rivers, water systems or washing machines. They can harbor a potential risk to human health serving as habitat for pathogens. Furthermore, biofilm growth within washing machines leads to biocorrosion and unpleasant odours. Therefore, the removal or prevention of biofilm growth is of great interest.

The relevance of biofilm EPS in terms of bacterial adhesion to surfaces has been indicated in several studies. Therefore, EPS can be one working point for laundry agents for the destabilization and detachment of biofilms.

**Objectives**

The objective of this investigation was to test the efficacy of different laundry agents on biofilms.

**Methods**

Biofilms grown in rinse water were treated with cleaning bases in a flushing chamber. Several concentration and fluxes of cleaning bases were tested. The attack of the cleaning agents on EPS components was analyzed by confocal laser microscopy after simultaneous staining of bacteria, proteins and polysaccharides.

**Conclusions**

Our findings showed that cleaning agents did not contribute an attack on specific polymer-groups of the EPS. The selection of the detergent as well as the applied shear forces were of rather great impact. Laundry agents containing oxidative bleach were much more effective than agents containing low or non bleach. CLSM images revealed the compact biofilm structure changed into a small- sized structured biofilm. Worst results were obtained by using liquid detergents. Furthermore, shear forces were of greater impact than the flushing duration and supported the effects of cleaning agents.

**Biofilms**

## **RESPONSE OF SESSILE CELLS OF CANDIDA SPECIES TO OXIDATIVE STRESS**

M. Cuéllar-Cruz<sup>1</sup>, I. Serrano-Fujarte<sup>1</sup>, E. López-Romero<sup>1</sup>, R. Zazueta-Sandoval<sup>1</sup>

<sup>1</sup>Biología, Universidad de Guanajuato, Guanajuato, Mexico

### **Background**

The biofilms of *Candida* species are associated with high indices of hospital morbidity and mortality [1,2]. Sessile cells are highly resistant to antifungals and to the host mechanisms of defense [1,3-5]. Though the ability of some *Candida* species to form biofilms on various medical implants has been evaluated as well as their response to oxidative stress [4,6], it is however important to investigate how the reactive oxygen species impacts on sessile cells of different *Candida* species.

### **Objectives**

To evaluate the response of oxidative stress on biofilm formation by *C. albicans*, *C. glabrata*, *C. krusei* and *C. parapsilosis*.

### **Methods**

Sessile and control cells of *Candida* species were exposed to increasing concentrations of H<sub>2</sub>O<sub>2</sub>. Biofilms were observed by scanning electron microscopy and quantified by the XTT assay.

### **Conclusions**

To our knowledge, this is the first report describing the effect of oxidative stress on biofilm formation by four *Candida* species *in vitro*. Our results suggest that candidiasis *in vivo* is a multifactorial and complex process where the human immune system and the adaptability of the pathogen should be considered altogether to provide an effective treatment of the patient.

<sup>2</sup>Costerton Biofilm Center Department of International Health Immunology and Microbiology,  
University of Copenhagen, Copenhagen, Denmark

### **Background**

The *fap* operon is present in the majority of *Pseudomonas* species and encodes for the *Fap* functional amyloid system, which is associated with cell aggregation and enhanced biofilm formation. Six genes make up the operon.

### **Objectives**

However, it is so far unknown how the *fap* operon is regulated.

### **Methods**

In this study, a biotinylated dsDNA probe was constructed in order to isolate potential DNA binding molecules, which specifically associate with the promoter region of the *fap* operon of the amyloid expressing *Pseudomonas* sp. UK4 and potential transcription factors were identified using LC-MS/MS taking advantage of a closed genome sequence. Two global regulators (MvaU and MvaT) were found to interact specifically, with the *fap* promoter. Specific binding of the alternative sigma factor (RpoN) was also observed. The latter observation is interesting as a gene encoding an RpoN activator protein is located next to the *fap* operon. Therefore, we created overexpression and deletion mutants of *Pseudomonas* sp. UK4 with the RpoN activator protein and the two general transcription regulators MvaU and MvaT.

### **Conclusions**

A hydrolysis probe based qPCR assay was developed in order to determine the effect of all these gene regulatory players on the *fap* operon. Consequently, the effect of elevated and decreased levels of c-di-GMP was also studied and experiments will show how these regulators affect transcription of the *fap* operon. This study contributes with an increased understanding of the transcriptional machinery that

control Fap-mediated biofilm formation. In the future, this regulatory system could be an important target in antibiofilm strategies.

## **EFFECT OF DENTAL BIOMATERIALS ON STREPTOCOCCUS MITIS/HUMAN GINGIVAL FIBROBLASTS CO-CULTURE**

M. Di Giulio<sup>1</sup>, E. Di Campli<sup>1</sup>, S. Di Bartolomeo<sup>1</sup>, S. Zara<sup>1</sup>, S. Sancilio<sup>1</sup>, L. Cellini<sup>1</sup>

<sup>1</sup>Department of Pharmacy, University "G. D' Annunzio" Chieti, Chieti, Italy

### **Background**

The biocompatibility of oral biomaterials depends not only on the biomaterial properties, but also on the host and oral indigenous microbiota response.

### **Objectives**

A co-culture model of *Streptococcus mitis*/Human Gingival Fibroblast (HGF) was set-up to evaluate the biocompatibility of: 2-hydroxyethylmethacrylate (HEMA), triethyleneglycoldimethacrylate (TEGDMA) and new synthesized bioactive lactose-substituted chitosan-silver-nanoparticles (Chitlac-nAg) in colloidal solution and as thermosets coating.

### **Methods**

*S. mitis* was co-cultured with HGFs with the above mentioned materials in presence of saliva in terms of bacterial adhesion and aggregation, HGF cell toxicity, expression of apoptosis-associated proteins and intracellular signaling.

### **Conclusions**

HEMA treatment showed an increased aggregation and adhesion of *S. mitis* on HGFs, mediated by the PKCa/integrin b1 signalling system. HEMA treatment decreased viable eukaryotic cell that was balanced by the presence of bacteria and saliva.

Concerning TEGDMA, *S. mitis* growth was not decreased and large bacterial aggregates were present on HGFs. Moreover, *S. mitis* and saliva reduced the HGFs oxidative stress and apoptosis induced by TEGDMA treatment.

Chitlac-nAg colloidal solution, in the HGF/*S. mitis* co-culture, induced less numerous viable bacteria adhering to the HGFs, in respect to the control. For coated thermosets, our results showed that the Chitlac-nAg coated thermosets cytotoxicity exerted on HGFs was absent in the co-culture model, where HGFs adhere and migrate on biomaterial.

Taken together, our results shed new light on the interaction of dental biomaterials/Streptococci/HGFs occurring in oral environment, underling the

importance of the co-culture model, resulting closer to the *in vivo* situation, to obtain a more realistic outcome.

**IMPACT OF BIOFILM GROWTH PHASE, DIVERSITY AND EPS QUALITY ON THE REMOVAL EFFICIENCIES OF BIODISPERSANTS USED FOR REDUCING BIOFILM ADHESION IN COOLING TOWERS**

F. Di Pippo<sup>1</sup>, L. Di Gregorio<sup>2</sup>, V. Tando<sup>2</sup>, S. Rossetti<sup>2</sup>

<sup>1</sup>*Department of Earth System Science and Environmental Technologies, CNR-IRSA National Research Council Water Research Institute CNR-IAMC National Research Council Institute for Coastal Marine Environment Località S a Mardini Torregrande Oristano Italy., Monterotondo Roma, Italy*

<sup>2</sup>*Department of Earth System Science and Environmental Technologies, CNR-IRSA National Research Council Water Research Institute, Monterotondo Roma, Italy*

**Background**

Biocides are commonly used to control unwanted biofilm development in cooling tower. The more environmentally friendly biodispersants can also be used, but little information is available on the efficiency of their application, likely affected by the biofilm structure, composition and growth phase.

**Objectives**

The objective of this work was to study the structure and diversity of biofilms developed from makeup water used in a full scale industrial cooling tower. The efficacy of the biodispersant was further evaluated on biofilms at different growth phase.

**Methods**

Biofilms were grown on glass slides, in a batch system, using as source community the cooling tower makeup water under four different nutrient conditions. The taxonomic bacteria affiliation was investigated by Fluorescence *In Situ* Hybridization (FISH) and diversity index was calculated. EPS were detected *in situ* by epifluorescence microscopy after staining with fluorochromes. A biodispersant commonly utilized in full scale cooling towers was then used and removal efficiencies at different stage of development were evaluated.

**Conclusions**

FISH allowed to identify about 90% of total bacteria, mainly belonging to *Proteobacteria*. Starting from the source community, biofilms showed an initial increase in biodiversity likely due to the functional niche diversification. Then, diversity decreased, mainly due to the adhesion of eukaryotes and to the concurrent reduction in bacteria taxon richness. The removal efficiencies of biodispersant decreased over time likely due to the higher biofilm stability at the late growth stage, where an increase of  $\alpha$  and  $\beta$  glucans, mainly found surrounding eucaryotic and

alphaproteobacterial cells, was observed.

**ΔPPIB ENHANCED MOTILITY AND BIOFILM FORMATION ABILITY IS POSSIBLY MEDIATED THROUGH CHANGES IN THE PPIB INTERACTIONS WITH SOME OF ITS PREY PROTEINS**

M. Dimou<sup>1</sup>, A. Skagia<sup>1</sup>, A. Venieraki<sup>1</sup>, E. Vezyri<sup>1</sup>, P. Katinakis<sup>1</sup>

<sup>1</sup>Department of Crop Science, Agricultural University of Athens, ATHENS, Greece

**Background**

*E. coli* ppiB is a peptidyl-prolyl *cis/trans* isomerase with chaperone activity. Δ*ppiB* strain shows enhanced swimming and swarming motility as well as biofilm formation ability.

**Objectives**

We hypothesize that the effects of ppiB on such cellular behaviors are likely accomplished through its protein interactions. Using a candidate approach we aim to identify multicopy suppressors of the Δ*ppiB* phenotypes and to characterize protein interactions with putative ppiB prey proteins.

**Methods**

Based on data provided by IntAct database we considered available ppiB prey proteins as putative interacting partners. To address whether these proteins could be direct effectors inhibiting motility or biofilm formation we over-expressed each of them in the Δ*ppiB* cells and checked for restoration of the corresponding phenotypes.

Further, we examined possible protein interactions with ppiB under native or denaturing prey conditions. To explore the potential involvement of the PPIase active site on the binding of ppiB to these proteins, we determined the inhibitory effect of each of them on the PPIase activity of ppiB.

**Conclusions**

Both the hyper-motility and enhanced biofilm formation ability of Δ*ppiB* strain was reversed by over-expression of certain prey proteins albeit different in each condition. With very few exceptions, we were not able to detect stable protein complexes, probably an indication for weaker transient interactions. However, under denaturing prey conditions, more interactions were revealed suggesting that ppiB is able to recognize denatured preys. A decrease in the ppiB PPIase activity, in the presence of many of them, further supports many of the putative associations.

## EFFECT OF SHEAR STRESS ON PSEUDOMONAS AERUGINOSA ISOLATED FROM THE CYSTIC FIBROSIS LUNG

J. Dingemans<sup>1</sup>, A. Crabbé<sup>2</sup>, R. Van Houdt<sup>3</sup>, A. Malfroot<sup>4</sup>, P. Cornelis<sup>5</sup>

<sup>1</sup>Bio-engineering Sciences, Vrije Universiteit Brussel, Brussels, Belgium

<sup>2</sup>Laboratory of Pharmaceutical Microbiology, Universiteit Gent, Gent, Belgium

<sup>3</sup>Unit of Microbiology, Belgian Nuclear Research Centre SCK•CEN, Mol, Belgium

<sup>4</sup>Department of Pediatric Pulmonology Cystic Fibrosis Clinic and Pediatric Infectious Diseases, UZ Brussel, Brussels, Belgium

<sup>5</sup>Bio-engineering Sciences, Vrije Universiteit Brussel Brussels, Brussels, Belgium

### Background

Chronic *Pseudomonas aeruginosa* lung infections are the main cause of morbidity in cystic fibrosis (CF) patients. Previously, we have sequenced the genome of the transmissible Belgian epidemic strain CF\_PA39. This CF-adapted strain has been present in the UZ Brussel hospital environment for at least ten years. Furthermore, earlier experiments showed that culturing *P. aeruginosa* PAO1 in a low fluid shear environment, obtained by means of the Rotating Wall Vessel (RWV) technology, leads to the formation of a biofilm phenotype comparable to that observed in the CF lung.

### Objectives

To study the effect of fluid shear on biofilm formation by an adapted *P. aeruginosa* CF strain in artificial sputum medium (ASM) at the genotypic, transcriptomic, and phenotypic level.

### Methods

In this study, an RWV experiment was performed that closely resembled the *in vivo* situation by inoculating this adapted CF isolate in ASM in the RWV either with or without two glass beads, simulating high and low fluid shear conditions, respectively. Scanning electron microscopy (SEM) was utilized to determine biofilm formation in both conditions, while RNAseq and qPCR was used to study gene expression in both conditions.

### Conclusions

Increasing fluid shear in the RWV model disrupted biofilm formation of an adapted *P. aeruginosa* CF isolate.

In accordance with the biofilm disruption, several genes involved in denitrification, tryptophane synthesis, choline metabolism, and alginate biosynthesis were down-regulated in the high fluid shear condition, resembling the planktonic stage of growth. Furthermore, we identified small RNAs that are differentially expressed.

<sup>2</sup>*Biotechnology, Hochschule Bremerhaven, Bremen, Germany*

<sup>3</sup>*Chair in Nanotechnology Water Research Center, Sultan Qaboos University, Muscat, Sultanate of Oman*

### **Background**

It has been shown that zinc oxide (ZnO) nanostructures can photocatalytically inhibit growth of fresh water bacterial and fungal strains under solar irradiation.

### **Objectives**

The objective of this study was to investigate the prevention of formation of marine biofilms by ZnO nanorod coatings in the laboratory and out-door experiments.

### **Methods**

ZnO nanorod coatings were fabricated on microscope glass substrates by a simple hydrothermal technique using equimolar solutions of 10 mM zinc nitrate and hexamethyltetramine. In laboratory conditions, upon 5 h of white light irradiation (light intensity= 100 Klx from a tungsten-halogen lamp), nanorod coatings significantly reduced the growth of marine bacterium *Acinetobacter* sp. and inhibited biofilm formation as compared to coatings kept in the dark (not exposed to light). In the continuous 7 days out-door experiment conducted in an aquaria (volume = 70 L) with sea water collected from Oman sea (Muscat, 23°34'55" N, 58°36'27" E), the nanorod coatings significantly reduced density of bacteria in comparison to the control (no coatings). In the absence of sunlight, test and control slides were equally colonized by bacteria. *De novo* sequencing of bacterial biofilms on MiSeq system® demonstrated that different communities were formed in the presence and absence of light on nanorod coatings.

### **Conclusions**

Our study suggests that ZnO nanorod coatings effectively prevent biofilm formation and can be used as a novel green antifouling technology.

**Bacterial Alpha-Amylase Enzyme with Inhibition Effect on Biofilm Formation in Clinical Isolates of *Acinetobacter baumannii***

D. Erdonmez<sup>1</sup>, K. Erkan<sup>2</sup>

<sup>1</sup>BIOLOGY, AKSARAY UNIVERSITY, AKSARAY, Turkey

<sup>2</sup>BIOLOGY, HACETTEPE UNIVERSITY, ANKARA, Turkey

**Background**

*Acinetobacter baumannii* is a pathogen with a high quality to form biofilm which can be isolated from different environmental sources. In addition, pathogenicity and biofilm formation associated with infectious agent.

**Objectives**

In this study, we investigated that degradation of biofilm formation by *Acinetobacter baumannii* is determined with amylase enzyme from *Bacillus amyloliquefaciens*.

**Methods**

*Bacillus amyloliquefaciens* is amylase enzyme producer which was obtained from Hacettepe University Department of Biology/Biotechnology. The biofilm forming ability in clinical isolates of *Acinetobacter baumannii* was determined by both microscopic and spectrophotometric analyses with using 24-well polystyrene plates.

**Conclusions**

According to results, amylase which obtained from *Bacillus amyloliquefaciens* was observed to inhibit biofilm formation in *Acinetobacter baumannii*. In continuous, amylase enzyme prevent to increase *Acinetobacter baumannii* cell population. As well as, in most of pathogen bacteria like *Acinetobacter baumannii*, amylase enzyme is considered to degradation of biofilm formation. In a result, amylase enzyme can be used as a drug supplement.

#### EFFECT OF SUBINHIBITORY CONCENTRATION OF SILVER NANOPARTICLES ON ADHESION OF GRAM-POSITIVE AND GRAM-NEGATIVE BACTERIA ONTO POLYSTYRENE SURFACES

P.E. Fernandes<sup>1</sup>, R.B.T. Alves<sup>1</sup>, N.J. Pimentel-Filho<sup>2</sup>, D.S. Costa<sup>1</sup>, N.J. Andrade<sup>1</sup>, H.C. Mantovan<sup>2</sup>

<sup>1</sup>Tecnologia de Alimentos, Universidade Federal de Viçosa - UFV, Viçosa, Brazil

<sup>2</sup>Microbiologia, Universidade Federal de Viçosa - UFV, Viçosa, Brazil

#### Background

In biofilms, bacterial cells adhere irreversibly to a solid surface by extracellular polymeric substances. This way of life provides several advantages over the planktonic mode, as responses to environmental stress.

#### Objectives

The objective was determined the effect of subinhibitory concentration of silver nanoparticles (Ag-NPS) and silver nitrate (AgNO<sub>3</sub>) on adhesion of gram-positive and gram-negative bacteria.

#### Methods

Ag-NPs were synthesized by reduction of AgNO<sub>3</sub> with sodium citrate. Bacterial strains used were gram-positive *Staphylococcus aureus* ATCC 6538, *Bacillus cereus*, isolated from milk cooling tank and *Enterococcus faecalis* ATCC 51299 and gram-negative *Escherichia coli* ATCC 11229, *Salmonella enterica* serovar Typhimurium ATCC 13076 and *Pseudomonas aeruginosa* ATCC 15442. The minimum inhibitory concentration was determined by macrodilution technique according CLSI, 2003. Müller-Hinton broth supplemented with subinhibitory concentration of Ag-NPs or AgNO<sub>3</sub> were transferred to 96-wells polystyrene microtiter plates, and inoculated with 5,0 x 10<sup>5</sup> cfu/ml of cell suspension. After 48 h at 37°C, the optical density was determined at 600 nm and supernatant was discarded. The surface-attached cells were stained with crystal violet for 30 min and washed three times with water. The absorbance at 590 nm was determined by addition of ethanol.

#### Conclusions

Adhesion was estimated by calculating the ratio between the absorbance of violet crystal and the optical density of cells. Subinhibitory concentrations of Ag-NPs and AgNO<sub>3</sub> increased the adhesion of the gram-positive bacteria, probably, as response to stress. The adhesion of *E. coli* and *S. Typhimurium* was not affected by presence of Ag-NPs or AgNO<sub>3</sub>. However, *P. aeruginosa* adhesion decreased in the presence of Ag-NPs.

**FEMS-2440**

**Biofilms**

### **CANDIDA GLABRATA BIOFILMS RESPONSE TO AMPHOTERICIN B**

C. Fortuna Rodrigues<sup>1</sup>, S. Silva<sup>1</sup>, J. Salgado<sup>1</sup>, L. Abrunhosa<sup>1</sup>, A. Venâncio<sup>1</sup>,  
J. Azeredo<sup>1</sup>, M. Henriques<sup>1</sup>

<sup>1</sup>Centre of Biological Engineering, University of Minho, Braga, Portugal

#### **Background**

*Candida* species are responsible for recurrent human infections, mostly in immunocompromised patients, due to their high vulnerability. *Candida glabrata* has been showing to have a major role in these infections being the second most prevalent species involved in human fungemia. Amphotericin B (AmB), a common antifungal drug, is a hospital-environment exclusive polyene, normally being efficient when used to fight candidiasis.

#### **Objectives**

The main goal of this work was to infer about the influence of AmB in *Candida glabrata* biofilms formation and its effect on matrix composition and *ERG* genes expression.

#### **Methods**

*Candida glabrata* biofilms were formed in the presence of AmB and analyzed by dry weight. Moreover, *ERG* genes expression was evaluated by qRT-PCR and matrix was analyzed in terms of composition in carbohydrates, proteins, beta-glucans and a new finding: ergosterol.

#### **Conclusions**

In addition to an inefficient reduction of the *C. glabrata* biofilms, this work showed that *ERG* genes seem to be less involved than the matrix composition in *C. glabrata* biofilms response to AmB. Specifically, *C. glabrata* biofilms matrices respond with an increase of carbohydrates, particularly beta-1,3 glucans, and with a decrease of total proteins. The ergosterol values did not expressively changed in the presence of AmB.

The present work support the theory of multifaceted mechanisms developed by *C. glabrata* biofilms as response to the presence of AmB.

## **FLOW CELL ANALYSIS OF THE PROCESS OF BACTERIAL CELL ADHESION MEDIATED BY THE ADHESIVE NANOFIBER PROTEIN ATAA UNDER SHEAR STRESS**

Y. Furuichi<sup>1</sup>, K. Izumitani<sup>1</sup>, K. Hori<sup>1</sup>

<sup>1</sup>*Biotechnology, Nagoya University, Nagoya, Japan*

### **Background**

Elucidation of bacterial adhesion is important for preventing detrimental biofilm formation and for applying it to microbial immobilization. An environmental strain, *Acinetobacter* sp. Tol 5 shows nonspecific, remarkably high adhesiveness to solid surfaces through AtaA (*Acinetobacter* trimeric autotransporter adhesin) nanofibers.

### **Objectives**

We aim to examine the effects of flow rate on the adhesion and autoagglutination of resting Tol 5 cells to reveal adhesion property mediated by AtaA.

### **Methods**

Bacterial adhesion was analyzed through using a flow cell system and the shear stress of the flow was controlled by flow rates and the viscosity of cell suspension supplied with PEG-400. The biomass of attached cells was quantitatively measured by staining with crystal violet. The thickness of the cell clump adhered on the surface was measured by confocal laser scanning microscopy.

### **Conclusions**

Higher shear stress in the flow cell decreased bacterial adhesion and the thickness of cell clump formed on the flow cell surface. By contrast, the bacteria adhesion to well-plates was increased by mild agitation compared with that in a static condition due to enhanced autoagglutination of the cells. These results suggest that there is the optimum flow rate for cell adhesion in the balance between enhancement of autoagglutination due to the increase in the collision probability of bacterial cells and detachment of cells and/or inhibition of cell-cell or cell-surface interaction by shear stress.

**HRPB DEAD-BOX RNA HELICASE IS IMPORTANT FOR MOTILITY, BIOFILM FORMATION AND CANCER DEVELOPMENT IN XANTHOMONAS CITRI SUBSP. CITRI**

L.M. Granato<sup>1</sup>, S.C. Picchi<sup>2</sup>, M.O. Andrade<sup>3</sup>, M.A. Takita<sup>2</sup>, A.A. de Souza<sup>2</sup>, N. Wang<sup>3</sup>, M.A. Machado<sup>2</sup>

<sup>1</sup>Biotechnology, IAC-Centro de Citricultura Sylvio Moreira/UNICAMP, Cordeirópolis, Brazil

<sup>2</sup>Biotechnology, IAC-Centro de Citricultura Sylvio Moreira, Cordeirópolis, Brazil

<sup>3</sup>Microbiology, UF - Citrus Research and Educational Center, Lake Alfred, USA

**Background**

DEAD-box RNA helicases are proteins highly conserved, present in all eukaryotic cells and in many bacteria. DEAD-box RNA helicases are involved in various processes of RNA metabolism and play important roles, e.g., translation initiation, ribosome biogenesis and RNA decay. Several bacterial DEAD-box proteins have been studied extensively due to their importance in *E. coli*, *Bacillus subtilis* and *Staphylococcus*. Interestingly, in *Staphylococcus aureus*, the DEAD-box protein CshA was involved in biofilm formation via modulation of *agr* mRNA stability. However, the function of DEAD-box RNA helicases remains unexplored in relation to adhesion, biofilm formation or pathogenicity in *Xanthomonas citri*.

**Objectives**

To characterize the function of DEAD-box RNA helicase (XAC0293/HrpB) in relation to motility, biofilm formation and citrus canker development in *Xanthomonas citri* subsp. *citri*.

**Methods**

We conducted assays for analysis of sliding motility, biofilm formation on biotic surface and pathogenicity of the wild type and the *hrpB* mutant of *X. citri* subsp. *citri*. Expression of different genes between the wild type and mutant strains was determined by quantitative RT-PCR.

**Conclusions**

Deletion of the *hrpB* gene reduced the expression of type IV pili genes, which are required for motility, biofilm development and adherence. Our data show that HrpB regulates the mobility and adherence of the *X. citri* in host. HrpB hereby is the first DEAD-box RNA helicase in *Xanthomonas citri* that is implicated in the regulation of

pili genes and that it is involved in motility, biofilm formation and citrus canker development.

## **COMPARATIVE GENOMICS OF IRON TRANSPORTING SYSTEMS AND FUNCTIONAL ANALYSIS IN BACILLUS CEREUS STRAINS FOR GROWTH AND BIOFILM FORMATION**

H. Hayrapetyan<sup>1</sup>, M. Nierop Groot<sup>2</sup>, R. Siezen<sup>3</sup>, T. Abee<sup>1</sup>

<sup>1</sup>Food Microbiology, Wageningen University and Reserch Center, Wageningen, Netherlands

<sup>2</sup>Food Safety and Preservation, Top Institute of Food and Nutrition (TIFN), Wageningen, Netherlands

<sup>3</sup>Center for Molecular and Biomolecular Informatics, University of Nijmegen, Nijmegen, Netherlands

### **Background**

Human pathogens such as *Bacillus cereus* are in constant competition for iron with other microbes and their host. In most environments, including food and mammal hosts, iron is bound to complex compounds and is not readily available. However, pathogenic bacteria developed mechanisms to scavenge iron from a range of sources.

### **Objectives**

The objective of this study was to investigate the use of different complex and non-complex iron sources by *Bacillus cereus* reference strains ATCC14579 and ATCC 10987, and 20 undomesticated food isolates, for which growth phenotypes were linked to genotypes.

### **Methods**

Genome sequences were analysed for the presence of putative iron transport systems. Growth and biofilm formation were monitored in LB with and without iron scavenger Bibyridine and different iron sources. Transcriptome studies in *B. cereus* ATCC10987 revealed upregulation of many putative iron transport systems upon depletion of iron.

### **Conclusions**

All 22 *B. cereus* strains could effectively use Fe citrate and FeCl<sub>3</sub> for growth, and formation of air-liquid interface biofilms was promoted. Hemoglobin and Hemin were used by all, except one strain lacking functional petrobactin and IIsA systems. Interestingly, Hb and Hemin triggered a submerged type biofilm formation by several strains. Ferritin and transferrin could be used for growth only by three and six strains respectively, but biofilm formation was inhibited. Lactoferrin did not restore the growth, however it supported submerged biofilm formation by several strains. Knowledge of iron transport systems and their functioning can serve as an indicator for bacterial fitness in different environments including usage of host-derived iron sources.

**MICROSCOPIC ANALYSIS OF THE PROCESS OF BACTERIAL CELL ADHESION  
AND AUTOAGGLUTINATION MEDIATED BY THE ADHESIVE NANOFIBER  
PROTEIN ATAA**

K. Hori<sup>1</sup>, S. Yoshimoto<sup>1</sup>, Y. Furuichi<sup>1</sup>

<sup>1</sup>Dept. Biotechnology, Nagoya University, Nagoya, Japan

**Background**

Elucidation of bacterial adhesion is important for preventing detrimental biofilm formation and for applying it to microbial immobilization. An environmental strain, *Acinetobacter* sp. Tol 5 shows nonspecific, remarkably high adhesiveness to solid surfaces through AtaA (*Acinetobacter* trimeric autotransporter adhesin) nanofibers.

**Objectives**

We aim to reveal the mechanism of cell adhesion mediated by AtaA and describe the cell adhesion process in a microscopic level.

**Methods**

The time profile of cell adhesion was analyzed through confocal laser scanning microscopy (CLSM) and flow cell analysis. The mechanism of autoagglutination was described by clustering process of colloidal particles by measuring the surface potential of Tol 5 cells with and without AtaA nanofibers.

**Conclusions**

By the CLSM, Tol 5 wild-type (WT) but not  $\Delta ataA$  mutant was revealed to form a thick cell layer ( $> 30 \mu\text{m}$ ) with void structure on a glass surface. The process of the cell clumping was described by DLVO theory and CCA model, which were developed as colloidal aggregation models. The autoagglutination of Tol 5 cells was realized by Brownian motion and the collision of AtaA fibers, but not that of cell bodies. By flow cell analyses, it was demonstrated that autoagglutinated WT cells attached well to a glass surface, whereas its single cells hardly attached. These results suggest that autoagglutination greatly contributes to cell adhesion due to enlarged particle size.

<sup>2</sup>*Division of Animal Medicine, Animal Technology Institute Taiwan, Miaoli, Taiwan*

<sup>3</sup>*Institute of Statistics, National Tsing Hua University, Hsinchu, Taiwan*

**Background**

*Candida albicans* is a major fungal pathogen of humans. It is a commensal on the skin and mucosal surfaces, but can cause invasive and systemic infections particularly in the immunocompromised patients. *C. albicans* can easily form biofilm on supporting surfaces, such as mucosal surfaces and indwelling medical devices. Biofilms enhance *C. albicans* resistance to antifungals and may help cells to escape from the host immune systems.

**Objectives**

The identification and study of transcription factors related to biofilm formation can provide important insights into molecular mechanisms controlling biofilm formation.

**Methods**

The systems biology approach is a novel trend in biological research that focuses on the complex interactions among genes, proteins, and intracellular metabolites. Using systems biological approach, we identified several transcription factors that may involve in biofilm formation. *MSS11*-deleted mutant showed a defect in forming a mature biofilm and partially attenuates the virulence of *C. albicans* in a mouse model of infection. In contrast, deletion of the gene encoding another transcription factor enhanced cell adhesion and biofilm formation compared to wild type. Interestingly, this mutant also showed an increase in the expression of adhesin genes.

**Conclusions**

Taken together, our results support applying the systems biology approaches to study various aspects of fungal biofilm formation and pathogenesis.

**INTERFERENCE OF BIOFILM FORMATION BY LIPOPOLYSACCHARIDE O-ANTIGEN AND THE CAPSULE-LIKE COMPLEX OF FRANCISELLA TULARENSIS**

T. Inzana<sup>1</sup>, K. Freudenberger<sup>1</sup>, A. Champion<sup>1</sup>

<sup>1</sup>Biomedical Sciences and Pathobiology, Virginia Tech University, Blacksburg, USA

**Background**

*Francisella novicida* forms a robust biofilm on most surfaces, whereas *F. tularensis* subsp. *tularensis* and subsp. *holarctica* form little or only a poor biofilm. *F. novicida* colonies are also dark red on Congo Red agar, whereas *F. tularensis* colonies are light salmon. However, colonies of *F. tularensis* lipopolysaccharide O-antigen mutants are also dark red in color. We hypothesized that the O-antigen, or other surface components, of *F. tularensis* interferes with biofilm formation.

**Objectives**

Our objectives were to determine if mutants of *F. tularensis* lacking O-antigen and/or a capsule-like complex (CLC) were more capable of forming a robust biofilm than parent strains.

**Methods**

*F. novicida*, *F. tularensis* (types A and B), and mutants were grown in polystyrene wells or on glass coverslips, and biofilms examined by crystal violet staining, confocal laser scanning microscopy, and scanning electron microscopy. Biofilm-associated exopolysaccharide (EPS) was isolated by enzyme digestion and phenol extraction, and composition determined by gas chromatography-mass spectrometry.

**Conclusions**

O-antigen mutants of *F. tularensis* made a more robust biofilm than parent strains within 10 days incubation. However, only a mutant lacking both O-antigen and CLC attached better and made significantly more biofilm than the parent after 15 days incubation. Some *F. novicida* O-antigen mutants also formed significantly more biofilm than the parent. Optimum biofilm formation was dependent upon the growth medium. A novel EPS was isolated and identified as glucan from the *F. tularensis* biofilm. We conclude that the O-antigen and CLC interfere with *F. tularensis* biofilm formation, likely through interfering with attachment.

### **3D VISUALIZATION AND QUANTIFICATION OF BIOFILM IN POROUS MEDIA BY X-RAY TOMOGRAPHY**

T. Ivankovic<sup>1</sup>, S. Rolland du Roscoat<sup>1</sup>, C. Geindreau<sup>1</sup>, J.M.F. Martins<sup>2</sup>, Z. Huang<sup>3</sup>,  
P. Sechet<sup>3</sup>

<sup>1</sup>Laboratoire 3SR, Universite Grenoble Alpes, Grenoble, France

<sup>2</sup>LTHE, Universite Grenoble Alpes, Grenoble, France

<sup>3</sup>LEGI, Universite Grenoble Alpes, Grenoble, France

#### **Background**

The development of reliable models of biofilm growth in biofilters at the industrial scale, suffers from a lack of 3D measurements at the scale of the biofilter's constituents. Currently, only three experimental studies, using Synchrotron X-ray Microtomography, proposed protocols based on the use of different contrast agents to image such complex media at the pore scale.

#### **Objectives**

The aims of the present study, based on the adaptation of these protocols to laboratory X-ray microtomograph, are threefold:

- (i) the 3D visualization and quantification of the interface between the biofilm and the bulk fluid. This will give us access to the shape, the spatial distribution and volume of the biofilm at the pore scale ;
- (ii) the numerical evaluation of physical properties such as permeability or diffusivity arising in macroscopic models using up-scaling methods ;
- (iii) the evolution of the aforementioned biofilm characteristics with time and according to the operating conditions (flow rate, nutrient conditions.)

#### **Methods**

Thus, the *Pseudomonas putida* biofilms were grown on glass beads in small biofiltration columns. A new protocol permitting to avoid the use of contrast agent was proposed and 3D X-ray images of the biofilms grown under various operating conditions were obtained (i,iii).

#### **Conclusions**

The 3D microstructural properties were quantified using appropriated image processing tools (i) and the physical properties were estimated using numerical tools (ii). The representativity of the imaged volume was checked for both structural and physical properties giving access to some of the missing elements to build the macroscopic model.

**ANTI-BIOFILM FORMING EFFECT OF ESSENTIAL OILS ON LISTERIA MONOCYTOGENES IN MONO- AND MIXED CULTURES**

E. Kerekes<sup>1</sup>, M. Chandrasekaran<sup>2</sup>, S. Kadaikunnan<sup>2</sup>, N. Alharbi<sup>2</sup>, C. Vágvolgyi<sup>1</sup>, J. Krisch<sup>3</sup>

<sup>1</sup>Department of Microbiology, University of Szeged, Szeged, Hungary

<sup>2</sup>Botany and Microbiology Department, King Saud University, Riyadh, Saudi Arabia

<sup>3</sup>Institute of Food Engineering, University of Szeged, Szeged, Hungary

**Background**

*Listeria monocytogenes* can be found frequently in mono- or mixed culture biofilms. These make sanitization difficult and can lead to cross-contamination and food safety problems. Beside heat treatment, preservatives can be used to eliminate pathogens but sometimes they are not effective and can produce unpleasant by-products. Application of natural antimicrobial agents like essential oils (EOs) could be a potential solution.

**Objectives**

Our aim was to investigate the anti-biofilm forming effect of selected EOs and their major components on *L. monocytogenes* biofilms and on mixed-cultures of *L. monocytogenes* and *E. coli*.

**Methods**

MIC values were determined by micro-dilution method. Biofilm formation was conducted in microtiter plates; after 4 h adhesion time, fresh medium containing EOs or components was added in MIC/2 concentration. Biofilm formation was monitored by crystal violet staining. For mixed cultures *L. monocytogenes* and *E. coli* were mixed in 1:1 ratio and concentration intervals between the MIC values of the two bacteria were used.

**Conclusions**

In case of monocultures, cinnamon and cinnamaldehyde have the best anti-biofilm formation effect. For mixed cultures, the effect of the EOs was concentration dependent:  $\alpha$ -pinene and linalool showed better anti-biofilm forming effect than the parent essential oil.

**CHARACTERIZATION OF NaCl STRESS-INDUCIBLE PALMELLOIDS AND UNDERSTANDING THE ROLE OF A STRESS-RESPONSIVE GENE, *BOLA* FROM THE GREEN CHLOROPHYTE *CHLAMYDOMONAS REINHARDTII*.**

D. Khona<sup>1</sup>, S. Dongre<sup>1</sup>, C. Arraiano<sup>2</sup>, S. Shirolkar<sup>3</sup>, E. Hom<sup>4</sup>, M. Deodhar<sup>5</sup>, J. D'Souza<sup>1</sup>

<sup>1</sup>Biology, UM-DAE-Centre for Excellence in Basic Sciences, Mumbai, India

<sup>2</sup>Biology, Instituto de Tecnologia Química e Biológica Universidade Nova de Lisboa, Oeiras, Portugal

<sup>3</sup>Biology, Tata Institute of Fundamental Research, Mumbai, India

<sup>4</sup>Biology, University of Mississippi, Oxford, USA

<sup>5</sup>Botany, K. E. T's V. G. Vaze College, Mumbai, India

**Background**

*Chlamydomonas reinhardtii*, a unicellular green alga, is a preferred model organism for studying stress-induced responses. Depending on the stress dose and time of exposure, the flagella of this organism are paralyzed / lost and later cells manifest 'palmelloids' or apoptose. Palmelloids, akin to bacterial biofilms, are a stress-responsive temporary, dormant 'colonial' stage exhibiting conserved physiological changes.

**Objectives**

The current study deals with characterization of palmelloids formed by *C. reinhardtii* in response to NaCl stress and explores the role of a conserved stress-responsive gene family, *C. reinhardtii bolA* in biofilm / palmelloid formation.

**Methods**

A detailed morphological and biochemical analysis of NaCl stress inducible palmelloids was performed.

Drawing an analogy, it is known that the morphogene, *bolA*, significantly facilitates the formation of biofilms and induces morphological changes in response to stress in *Escherichia coli*. *Chlamydomonas reinhardtii* genome harbors five *bolA-like* genes. The ORF with highest homology to algal systems (*CrboLA-4*) was cloned and the protein over-expressed in *Escherichia coli*.

**Conclusions**

Palmelloids rapidly dissociated upon de-stress suggesting the reversibility of this phenomenon. The cells in palmelloids displayed conserved physiological features such as clustering of cells in a common envelope, decreased viability, accumulation of lipid and starch granules and presence of extracellular polysaccharides. An iTRAQ analysis of the spent medium from palmelloid-containing cells suggests a strong involvement of cell wall proteins. Further heterologous over-expression of *CrboLA-4* in *E. coli* did not affect its growth; but, induced biofilm formation and changed its morphology, indicating functional conservancy. Its role in the NaCl-induced palmelloidy remains to be explored.

**OLSBA OPERON INVOLVED IN ORNITHINE LIPID BIOSYNTHESIS AFFECTS VIRULENCE AND BIOFILM FORMATION OF PSEUDOMONAS AERUGINOSA**

J.H. Lee<sup>1</sup>, X.-H. Li<sup>1</sup>, J. Oh<sup>1</sup>, S. Kim<sup>1</sup>

<sup>1</sup>department of pharmacy, Pusan National University, Busan, Korea

**Background**

Ornithine lipids (OLs) are interesting bacterial lipids that are widely found in outer membrane of many Gram-negative bacteria, but not detected in Eukarya and Archaea. *Pseudomonas aeruginosa* has *olsBA* operon encoding acyltransferases that functions the OL biosynthesis. OlsBA works in two steps for the OL biosynthesis, in which OlsB transfers an acyl group to ornithine to make lyso-ornithine lipid and OlsA converts the lyso-ornithine lipid into ornithine lipid by another acyl-group transfer.

**Objectives**

Acyltransferase genes of *P. aeruginosa* were originally screened for the effect on the virulence and biofilm formation of *P. aeruginosa*. The *olsBA* operon was found to have significant pleiotropic effects on the virulence related-phenotypes of *P. aeruginosa*. In this study, we addressed how OlsBA modulates the virulence and biofilm formation of *P. aeruginosa*.

**Methods**

1) The virulence was investigated by using two different host models, *Tenebrio molitor*, an insect and *Caenorhabditis elegans*, a nematode. 2) The effect of the *olsBA* overexpression on biofilm formation in *P. aeruginosa* was analyzed in flow cell system. 3) The host response to OLs was monitored through the expressions of COX-2 and iNOS using Western blot and real-time PCR analyses.

**Conclusions**

We found that the overexpression of *olsBA* operon modulated some virulence related-phenotypes of *P. aeruginosa* by reducing the quorum sensing response. In addition, the overproduced OLs directly alleviate the virulence of *P. aeruginosa*, enhances biofilm formation, and modulates the host physiology.

### Background

Nitrogen dioxide is an air pollutant of increasing interest in biology. Exposure of animals to NO<sub>2</sub> results in several toxic effects, mostly lung injury.

### Objectives

Aware of the effect of NO<sub>2</sub> on pseudomonal biofilm formation, we looked for the mechanisms of bacterial response that could explain their resistance to NO<sub>2</sub>.

### Methods

The confocal microscopy was used for biofilm studying, completed by motility assays. In a second time, *in silico* and *in vitro* genomics tools were used to narrow our research scope. Additionally, in order to characterize the mechanism of *P. fluorescens* resistance to NO<sub>2</sub> pollution these data were completed with proteomics and lipidomics studies. For this purpose, the MALDI-TOF MS Imaging was coupled to HPTLC and compiled with the traditional GC-MS.

### Conclusions

When the NO<sub>2</sub> increases *P. fluorescens* biofilm formation, the bacterial motility decreases. In coherence, the level of cyclic di-GMP evolves in NO<sub>2</sub> exposed cells. The lipidic study shows no drastic change in membrane charge and its composition in phospholipids and fatty acids. This suggests that NO<sub>2</sub> free radical could freely pass through membrane. In contrast, NO<sub>2</sub> promotes an extensive modification in protein production, notably the over-production of the proteins of stress response, involved in oxidative stress tolerance and iron transport/metabolism. Thus both iron up-regulation and C-di-GMP level could be signals for biofilm development. This knowledge should probably offer therapeutical solutions in antibacterial treatment.

## **OXYGEN LIMITATION TRIGGERS PELLICLE FORMATION IN BURKHOLDERIA GLUMAE**

G. Kwak<sup>1</sup>, E. Goo<sup>1</sup>, H. Jeong<sup>1</sup>, I. Hwang<sup>1</sup>

<sup>1</sup>Agricultural Biotechnology, Seoul National University, Seoul, Korea

### **Background**

Bacteria adapt to unfavorable environmental conditions for survival. *Burkholderia glumae*, the causal agent of rice panicle blight, absolutely requires oxygen for respiration. For aerobes such as *B. glumae*, oxygen limitation is a serious problem for survival. Many bacteria including *B. glumae* possess genes encoding proteins with a PAS/PAC domain whose functions sense changing environments and manage gene regulation accordingly. Oxygen availability in bacteria is related to biofilm or pellicle formation. Cyclic-di-GMP synthesized by proteins carrying a GGDEF domain is a messenger for the pellicle formation.

### **Objectives**

We aimed to investigate how *B. glumae* adapts to oxygen availability

### **Methods**

Overnight culture of *B. glumae* grown in LB broth was serially diluted with the same medium to give approximately  $1 \times 10^7$  cells/ml. A portion of 200  $\mu$ l was placed in 96 well cell culture plates and incubated at 37°C without shaking. Growth was monitored from day 0 to day 7 of the incubation period. Morphologically altered colonies were isolated, and a mutation responsible for colony variation was identified by whole genome re-sequencing.

### **Conclusions**

Mutations in the *bpaA* (*B. glumae* pH associated protein A) gene encoding a protein possessing PAS/PAC and phosphatase domains conferred wrinkly colony types. A mutation in *bpaA* resulted in elevated expression of cellulose biosynthesis genes responsible for pellicle formation. Thus, mutations in *bpaA* and pellicle formation in oxygen limited conditions suggest how *B. glumae* has evolved to survive under unfavorable conditions.

**ROLE OF EACH EPM GENE ON THE FORMATION OF A NOVEL BIOFILM-  
SCAFFOLD EXTRACELLULAR POLYMER FROM PSEUDOMONAS**

K. Lee<sup>1</sup>, G.S. Ha<sup>1</sup>, J.B. Kang<sup>1</sup>, K.S. Kim<sup>1</sup>

<sup>1</sup>Department of Microbiology, Changwon National University, Changwon-si, Korea

**Background**

*Pseudomonas alkylphenolia* KL28 forms unique three-dimensional biofilm bodies depending on the environmental stimuli. It forms highly branched mushroom-like aerial architecture during vapor *p*-cresol utilization and circular floating pellicles on standing LB medium. These indicate that *P. alkylphenolia* is a good bacterial sample for studying bacterial community formation and cell-cell interactions. An *epm* gene cluster consisting of eleven genes showing deduced amino acid sequence similarities to those encoded on *alg* genes has been identified to be responsible for formation of the special biofilm structures.

**Objectives**

In this study, the role of each *epm* gene was studied in relation to the biofilm formation and polymer processing.

**Methods**

For this purpose, mutants specifically deleted in *epm* genes from an *epm*-overproducing spontaneous mutant SG1-WC1-10' were constructed. With those mutants, changes in surface-related phenotypes and polymer production were examined.

**Conclusions**

It was found that *epm* genes except *epmL* are required to form wrinkle colonies and mature biofilms including aerial architecture and circular floating bodies. Mutants in *epmI*, *epmJ*, *epmX* (acetylation, deduced from *alg* genes), *epmG* (epimerization), *epmE*, *epmK* (transporter) were still positive to polyuronic acid production. In addition, some of these *epm* genes cannot be substituted by *alg* genes. Thus, these results indicate that regardless of the similarities between Alg and Epm proteins the structure of Epm polymer derived from an *epm* gene cluster is different from alginate and the process of Epm polymer biosynthesis is different from that of alginate in *Pseudomonas*.

**Biofilms**

## **INDOLE EFFECT ON ANTHRANILATE DEGRADATION IN PSEUDOMONAS AERUGINOSA**

X. LI<sup>1</sup>, S. KIM<sup>1</sup>, J.-H. LEE<sup>1</sup>

<sup>1</sup>department of pharmacy, Pusan National University, Busan, Korea

### **Background**

Anthranilate and indole are alternative degradation products of tryptophan in nature. *Pseudomonas aeruginosa* produces anthranilate from tryptophan degradation. Previous studies showed that anthranilate and indole has an opposite effect on *P. aeruginosa* biofilm formation. While indole enhances the biofilm formation of *P. aeruginosa*, anthranilate was able to disintegrate the mushroom structure of biofilm.

### **Objectives**

We addressed how indole could enhance the biofilm formation of *P. aeruginosa* in relation to anthranilate degradation.

### **Methods**

*P. aeruginosa* biofilm formation was analyzed in flow-cell system. High Performance Liquid Chromatography was used to measure the level of anthranilate in *P. aeruginosa* culture supernatant. The effect of indole on AntR activity was analyzed by reporter fusion *in vivo* and gel shift assay *in vitro*.

### **Conclusions**

In *P. aeruginosa*, the transcription of *antABC* operon encoding anthranilate dioxygenase complex that functions to degrade anthranilate, was activated by the indole treatment. Although indole alone failed to activate AntR, co-addition of indole with anthranilate boosted the activation of AntR by anthranilate. As consequence, the anthranilate level in *P. aeruginosa* culture supernatant decreased. Since anthranilate has a biofilm-disintegrating effect, we suggest that indole may enhance the biofilm formation of *P. aeruginosa* by reducing anthranilate level through the modulation of AntR activity.

**TRIMERIC AUTOTRANSPORTER ADHESINS (TAAS) - STRUCTURAL STUDIES OF THE TRANSLOCATION PROCESS, AND PERSPECTIVES FOR ITS INHIBITION**

D. Linke<sup>1</sup>, S. Shahid<sup>2</sup>, I. Grin<sup>3</sup>, M. Habeck<sup>3</sup>, B. van Rossum<sup>2</sup>

<sup>1</sup>Biosciences, University of Oslo, Oslo, Norway

<sup>2</sup>NMR, FMP Berlin, Berlin, Germany

<sup>3</sup>Protein Evolution, MPI Developmental Biology, Tuebingen, Germany

**Background**

Trimeric autotransporter adhesins (TAAs) comprise a widespread family of adhesive molecules in Gram-negative bacteria, many of which are important virulence factors [1]. The prototypical trimeric autotransporter is the *Yersinia* adhesin YadA from *Yersinia enterocolitica*, which mediates attachment to collagen and other extracellular matrix (ECM) molecules, promotes serum resistance and mediates autoagglutination.

**Objectives**

The autotransport process depends on a conserved translocation domain and associated factors. Inhibiting this process is a possible antimicrobial strategy, as no homologous systems exist in Eukaryotes, and as many of the TAAs are important or even essential in host colonization by a broad range of Gram-negative pathogens.

**Methods**

We recently solved the structure of the *Yersinia* YadA translocation domain (using solid-state NMR [2]) and of a chaperone-like protein involved in the translocation of *Salmonella* SadA (using x-ray crystallography [3]). Conserved residues thought to be important for translocation are targeted by mutagenesis. Adhesion assays and antibody-based assays such as FACS are used to quantify translocation.

**Conclusions**

A better understanding of the translocation process on the molecular level is essential for efficient inhibition of the surface display of these important pathogenicity factors. The methods developed to quantify surface localization can be scaled up for systematic screens for antimicrobial substances.

## **DISSECTING METHANO- AND METHYLOTROPHIC BIOFILM FUNCTIONING IN A IODINE-RICH SUBSURFACE SPRING CAVERN**

T. Lueders<sup>1</sup>, C. Karwautz<sup>1</sup>, M. Stöckl<sup>1</sup>

<sup>1</sup>*Institute of Groundwater Ecology, Helmholtz Zentrum München, Munich Neuherberg, Germany*

### **Background**

Massive microbial biofilms have recently been discovered in a subsurface spring cavern fed by iodine-rich deep formation water with high thermogenic methane loading. The biomass produced by the microbes and exopolysaccharide slime completely covers the walls and ceilings of the cave, the latter bearing snottites of up to 10 cm length.

### **Objectives**

However, the nature of these unique biofilms as well as their ecophysiology are not yet understood.

### **Methods**

Our primary taxonomic characterization of the biofilms revealed a surprisingly diverse polymicrobial community assembly, substantiating a complex network of bacteria and archaea interacting within the sticky matrix. Distinct methanotrophic and methylotrophic populations within the *Alpha*-, *Beta*- and *Gammaproteobacteria* dominated the biofilms. *Methylophilaceae* and *Methylococcaceae* were abundant on the walls and especially in the cavern water, but not so in ceiling biofilms. Here, ribosomal and functional gene analysis hinted at dominating methylotrophic and potentially also iodine-cycling populations, thus supporting a hypothesized cycling of iodomethane in this system. Geochemical gradients in the cavern were clearly reflected within community assembly, as well as elemental and stable isotope composition of the biofilms. These findings were further supported by distinct microaerophilic oxidation rate measurements for methano- and methylotroph substrates in spatially resolved biofilm samples. Ongoing work involves the elucidation of ecological niche partitioning between strict methanotrophs and potential methyl halide-oxidising populations in this unique habitat.

### **Conclusions**

In conclusion, primary insights into a dominantly chemolithoautotrophic natural biofilm system are revealed, thriving on deep subsurface energy inputs but only a few meters under our feet.

**FEMS-0943**

**Biofilms**

## **EFFECT OF SUBINHIBITORY CONCENTRATIONS OF CEFOTAXIME ON BIOFILM FORMATION IN STREPTOCOCCUS PNEUMONIAE**

M. Luo<sup>1</sup>, I. Ang<sup>1</sup>, V. Liyanapathirana<sup>1</sup>, M. Ip<sup>1</sup>

<sup>1</sup>Microbiology, The Chinese University of Hong Kong, Shatin, Hong Kong China

### **Background**

*Streptococcus pneumoniae* forms biofilm to persist in the human nasopharynx. Biofilms are often associated with pneumococcal pneumonia and otitis media.  $\beta$ -lactam agents remain the first line antibiotic for the treatment of *S. pneumoniae* infections. Subinhibitory concentrations of antibiotics have been reported to enhance biofilm formation.

### **Objectives**

This study aims to evaluate the effect of subinhibitory concentrations of a third generation cephalosporin, cefotaxime (CTX) on biofilm formation in *S. pneumoniae*.

### **Methods**

The effect of CTX (at 1/2, 1/4 and 1/16 MIC) were tested against biofilm formation in R6 and four clinical isolates in 24-well microtiter plates. Crystal violet (CV) staining and colony forming unit (CFU) were used to quantify biofilm biomass. Similar experiments were carried out with erythromycin and ciprofloxacin.

CV staining results showed that 1/2 MIC CTX resulted in 52.3%, 64.9%, 68.2%, 69.5% and 84.5% (all  $p$  values  $<0.01$ ) reduction in biomass of biofilm for R6 and the clinical strains tested. 1/4 MIC CTX led to 13.2% to 57.5% ( $p$  value  $<0.01$ ) reduction of biofilm while the inhibitory effect of 1/16 MIC CTX on biofilm formation were insignificant ( $<20\%$  inhibition). Living bacterial cells of R6 and two cefotaxime resistant strains recovered from biofilms unexposed to CTX were  $1.5 \times 10^8$ ,  $3.6 \times 10^4$  and  $1.3 \times 10^4$  CFU/well, respectively and decreased to  $4.7 \times 10^7$ , 53 and 43 CFU/well, respectively when exposed to 1/2 MIC CTX. Subinhibitory concentrations of non- $\beta$ -lactam antibiotics showed no significant influence on biofilm formation.

### **Conclusions**

Subinhibitory concentrations of CTX significantly inhibited biofilm formation.

**FEMS-1967**

**CHARACTERIZATION OF A NAPHTHALENE-DEGRADING MULTI-SPECIES BIOFILM ISOLATED FROM OIL-CONTAMINATED GROUND WATER**

S. Martirani Von Abercron<sup>1</sup>, P. Marín<sup>1</sup>, M. Solsona-Ferraz<sup>1</sup>, S. Marqués<sup>1</sup>

<sup>1</sup>*Environmental department, Estación Experimental del Zaidín-  
Consejo Superior de Investigaciones Científicas, Granada, Spain*

**Background**

Environmental microorganisms exist predominantly as biofilms and gain high tolerance to environmental stresses. Biofilm systems are especially suitable for the treatment of recalcitrant compounds as polycyclic aromatic hydrocarbon (PAH) because of their high microbial biomass and ability to immobilize compounds. To our knowledge, reports on naphthalene degradation by biofilm-forming bacteria are limited. In this study we isolated multi-species biofilm degrading naphthalene from oil-contaminated ground water (oil refinery, Murcia, Spain).

**Objectives**

The aims of this work were to characterize the biofilm microbial community and the biofilm structure and to isolate the bacteria involved in the biofilm formation and degradation of naphthalene.

**Methods**

The microbial community composition was characterized by culture dependent and molecular methods. For a qualitative understanding of biofilm structure and composition we used Scanning Electron Microscope (SEM). We also designed degenerated probes to detect and amplify naphthalene dioxygenase *nahA* gene homologues from environmental DNA and bacterial isolates.

**Conclusions**

Molecular analyses showed that the initial community was dominated by Betaproteobacteria (79% *Rhodospirillum rubrum*, 6% *Azotobacter*). After enrichment on naphthalene minimal medium we found Betaproteobacteria (54% *Variovorax*) and Alphaproteobacteria (43% of a *Xanthobacteraceae* strain) as dominant bacteria. We isolated members of *Microbacterium*, *Starkeya*, *Rhizobium*, *Brevundimonas*, *Variovorax*, *Pseudomonas*, *Pseudoxanthomonas*, *Epilithonimonas* and *Aquabacter*. Some of the isolates degraded naphthalene in pure culture and some other were able to produce biofilm. Homologues of *nahA* genes could be retrieved from the enrichment cultures and from some isolates.

**NITRIC OXIDE (NO) DONORS TO DISPERSE BIOFILMS OF INDUSTRIAL SIGNIFICANCE FORMED BY SALMONELLA ENTERICA, PATHOGENIC ESCHERICHIA COLI AND LISTERIA SP.**

M. Marvasi<sup>1</sup>, I. Durie<sup>2</sup>, R. Carvalho Prado<sup>1</sup>, A. Satkute<sup>1</sup>, M. Matuszewska<sup>1</sup>

<sup>1</sup>Natural Science, Middlesex University, London, United Kingdom

<sup>2</sup>Soil and Water Science, University of Florida, Gainesville, USA

**Background**

Biofilms formed in post-harvest production facilities are recalcitrant reservoirs of pathogens, which are difficult to control. Pathogens in biofilms are resistant to common disinfectants and their mechanical removal is only partially effective. Therefore, novel approaches for controlling biofilms are needed. Recent discoveries of the function of nitric oxide in dispersing preformed biofilms offer an opportunity to test the feasibility of using this gas in industrial applications.

**Objectives**

Determine the effect of several nitric oxide donors on biofilm of *Salmonella enterica*, *Escherichia coli* and *Listeria innocua* preformed on surfaces of industrial interest.

**Methods**

Biofilms were pre-formed in appropriate media for 24 hours or 1 week in 96-well plastic plates (polypropylene, polystyrene). After incubation, medium was removed and nitric oxide donors were resuspended in Phosphate Saline Buffer (PBS) and added to the wells using different concentrations. Biofilms were exposed to Molsidomine and MAHMA-NONOate donors from 2 hours to 6 hours at 22°C and 4°C to mimic the post-harvest environments. Dispersal was measured by staining the remaining biofilms using crystal violet or using a GFP labeled *Salmonella* strain. The donors were also tested in association with a cellulose nanocrystals hydrogel (CNC).

**Conclusions**

Molsidomine and MAHMA-NONOate were able to disperse at least 50% of the biofilms preformed by human pathogens, *Salmonella enterica* 14028, *Escherichia coli* O157 (EHEC). The association of the two nitric oxide donors with cellulose nanocrystals was also effective in dispersing *Salmonella* preformed biofilms on polypropylene up to 15% of the total biomass. Our results show that nitric oxide donors expand the toolset of proactive solutions for removing industrial biofilms.

**Effect of pomegranate peel extract on biofilm and planktonic cells of *Candida albicans***

H. Merzouk<sup>1</sup>, M. Chibane<sup>2</sup>

<sup>1</sup>Laboratoire de microbiologie alimentaire, dép. SA. FSNV, Université A/Mira, Bejaia, Algeria

<sup>2</sup>Faculté de biologie, université de Bouira, Algeria

Background: Pomegranate peel is used by many people against diarrhea, ulcers, periodontal disease, stomatitis and pharyngitis. *Candida albicans* can infect any part of the body (gum, tongue, toes...) with tissue invasion thus inducing candidiasis. *Candida* infections are difficult to manage due to their persistent nature and the Biofilm growth of this yeast serves as an increasing source of clinical infections.

Objectives : This study investigates the antioxidant activity of acetone peel extract of sour pomegranate peel named Quares (QE) and its effect against biofilm and planktonic cells of *Candida albicans*.

Methods: acetone 50% (v/v) was used for phenolic compounds extraction. The antifungal activity is evaluated using three strains of: CA1, CA2 and CA3. Various concentrations have been used to determine the MIC. Preliminary screening of activity: The agar disc diffusion method was conducted. The concentrations tested are 10mg/disc to 0.5mg/disc. Two models were used for the biofilm formation inhibition of *Candida albicans* on micoplaque (Hamada et al., 1978) and on hydroxyapatite discs (Guggenheim, 2001). The samples were then viewed under a scanning electron microscope.

Results and discussion: The extract from the variety QE showed a high content of total polyphenols. The inhibition percent of H<sub>2</sub>O<sub>2</sub> is 96.32 ± 0.56 %. The inhibition of *Candida albicans* biofilm formation on hydroxyapatite test showed strong inhibitory action against the strains in this order CA1 > CA3 > CA2.

Conclusion: This study reports the high content of phenolic compounds of pomegranate peel extract, antioxidant activity and *Candida albicans* biofilm inhibition.

Faculty of Biology sciences Tonekabon Branch Islamic Azad University Iran,  
Tonekabon, Iran

Background: Nowadays, mortality and morbidity due to infections caused by biofilm on medical devices such as catheter and implants are increasing and *Candida* has become one of the most common causes of nosocomial infections. One of the most important characteristics of biofilms is broad-spectrum resistance to antimicrobial drugs. However, too much using of this medicine can lead to the resistance of *Candida* species to fluconazole. Method: A total of 60 samples of medical devices attached to patients in ICU were investigated. Yeast colonies isolated from medical devices using routine laboratory procedures were identified. The MIC of fluconazole for all samples was carried out using Broth Microdilution according to CLSI. To assess biofilm formation by MTT, the experiment was carried out in a 96-cell microplate. Over half of the isolates of *Candida* had the ability to form biofilms, and the ability of biofilm formation was read by ELISA reader at a wavelength of 570 nm. Results: Out of 60 samples, 48 isolates of *Candida* with an abundance of *Candida albicans* (42%), *C. glabrata* (27%), *C. kruise* (17%) and *C. tropicalis* (14%) were identified. Among the isolates, 9 were susceptible to fluconazole (19%), 10 cases were dose dependent (21%) and 29 were resistant to fluconazole (60%). *Candida* isolates had the ability to form biofilms. *C. albicans* and *C. tropicalis* had the maximum and minimum power of biofilm formation respectively. Conclusions: The results showed that *Candida* was resistant to fluconazole. All resistant isolates had the ability to form biofilms.

**MICROFLUIDIC MODEL FOR THE INVESTIGATION OF PSEUDOMONAS  
AERUGINOSA BIOFILMS**

S. Neethirajan<sup>1</sup>, E.V.A.N. Wright<sup>1</sup>, X.U.A.N. Weng<sup>1</sup>

<sup>1</sup>*Biological Engineering, University of Guelph, Guelph, Canada*

**Background**

*Pseudomonas aeruginosa* is an opportunistic pathogen due to its capacity to form recalcitrant biofilm structures, while cohabiting with other harmful/pathogenic species and harboring the capability to release toxins that cause tissue necrosis. *P. aeruginosa* has been implicated in a number of microbially-induced or aggravated diseases, including cystic fibrosis and wound infections (e.g. burns, bites). Very little is known about the complex interactions that occur within polymicrobial communities and few tools exist for studying these interactions.

**Objectives**

In this study, we report on the development of a microfluidic model that mimics the relevant physiological properties of the wound microenvironment while incorporating materials present in the human extracellular matrix/wound environment.

**Methods**

We have validated the robustness of our model comparing traditional GFP-tagging to new fluorescent staining techniques to visualize/resolve individual species within a polymicrobial habitat. We have also demonstrated that chemotactic stimuli may be incorporated into our model through specialized ports in our chamber; we can readily monitor changes in motility in response to the introduction of amino acids, such as arginine and glutamine.

## Conclusions

We show that our model can be used to investigate the spatio-temporal mechanobiological structures of the wound environment, which will significantly contribute to our understanding of the development and progression of polymicrobial biofilm infections and its interactions with the host environment. Through the implementation of microfluidic platforms, we pose complex and relevant questions that may enhance our understanding of microbial interactions, all with the goal of

identifying new and specific targets for more effective antimicrobial therapies.

<sup>3</sup>Food Science and Technology,  
Institute of Food Nutrition and Human Health Massey University, Palmerston North,  
New Zealand

**Background**

*Listeria monocytogenes* is a foodborne human pathogen which is commonly found in the environment and is capable of withstanding environmental threats by adhering to surfaces to form a biofilm. Biofilm formation is believed to be a major factor for cross-contamination in food processing premises and therefore, elucidating the molecular mechanism of biofilm formation in *L. monocytogenes* can contribute to secure food safety.

**Objectives**

To identify genes involved in biofilm formation of *L. monocytogenes* 15G01

**Methods**

A library of 6,500 mutants was constructed via transposon mutagenesis of *L. monocytogenes* 15G01, a persistent strain in New Zealand seafood processing premises, with the Himar1 mariner-based transposon. This library was screened for altered biofilm formation using a microtiter plate assay, using conditions defined as optimum through preliminary studies. Quantification of biofilm mass was undertaken by optical density measurement after staining with crystal violet. Mutants of interest were selected through statistical analysis (two-sample t-test,  $p \leq 0.05$ ). The insertion site of the transposon was identified through semi-arbitrary PCR followed by DNA sequencing or by genome sequencing, and the inactivated loci analysed using BLAST.

**Conclusions**

Sequencing results revealed genes previously known to be involved in biofilm formation by *Listeria monocytogenes* and/or other bacterial species, which corroborates the method of transposon mutagenesis for functional analysis of biofilm formation. Furthermore, in this study, new genes influencing biofilm formation (either positively or negatively) have been identified. Further functional analysis of these genes is ongoing to elucidate their roles in biofilm formation.

**HYPOCHLORITE-INDUCED OXIDATIVE STRESS STIMULATES C-DI-GMP SYNTHESIS AND BIOFILM FORMATION IN PSEUDOMONAS AERUGINOSA**

J. Overhage<sup>1</sup>, N. Stempel<sup>1</sup>, M. Nusser<sup>1</sup>, L. Güdemann<sup>1</sup>, A. Neidig<sup>1</sup>, G. Brenner-Weiss<sup>1</sup>

<sup>1</sup>Department of Interface Microbiology, Karlsruhe Institute of Technology, Karlsruhe, Germany

**Background**

The opportunistic human pathogen *Pseudomonas aeruginosa* is able to adapt to a variety of often harmful environmental conditions due to different survival strategies including the formation of resistant biofilms.

**Objectives**

In this study, we investigated the adaptation of *P. aeruginosa* towards hypochlorite (HOCl), a strong oxidant used by human neutrophils to kill invading bacteria and which can be found in chronically inflamed host tissue, e.g. in the lungs of CF patients

**Methods**

In static biofilm assays, we observed a significant increase of up to 3-fold in initial cell attachment in the presence of sub-lethal hypochlorite concentrations. Transcriptome analyses revealed a substantial upregulation of genes involved in oxidative stress response as well as biofilm formation in the presence of hypochlorite. Among others, we identified a 26-fold upregulation of ORF PA3177 coding for a putative diguanylate-cyclase (DGC), which catalyzes the synthesis of the second messenger c-di-GMP, and therefore influences motility, biofilm formation and persistence in *P. aeruginosa*. Subsequent LC-MS/MS analyses revealed a strong increase in c-di-GMP levels suggesting a key role of this second messenger in hypochlorite induced adhesion and biofilm development. The DGC PA3177 was further characterized in more detail demonstrating its involvement in motility, biofilm formation, antimicrobial resistance and persistence in *P. aeruginosa*. Using a subset of different mutant strains, we were able to show that both the pel and psl exopolysaccharides are effectors in the PA3177-dependent c-di-GMP network.

**Conclusions**

Our results demonstrate that host-derived antimicrobials are sensed by invading bacteria and exert a huge impact on bacterial pathogenesis including biofilm formation.

<sup>2</sup>Pediatric Infectious Diseases and Immunity, Erasmus MC-Sophia Children's Hospital, Rotterdam, Netherlands

<sup>3</sup>Division of Pediatric Infectious Diseases, Hauner Children's Hospital Ludwig-Maximilian Universität München, München, Germany

### **Background**

*Enterococcus faecium* is an important nosocomial pathogen causing biofilm-mediated infections. Elucidating *E. faecium* biofilm pathogenesis is pivotal for development of new strategies to treat these infections. In several bacteria extracellular DNA (eDNA) and proteins act as matrix components contributing to biofilm development.

### **Objectives**

In this study, we investigated biofilm formation capacity and the role of eDNA and secreted proteins in 83 *E. faecium* strains with different phylogenetic origin that clustered in clade A1 and clade B.

### **Methods**

Although there was no significant difference in biofilm formation between *E. faecium* strains from both clades, addition of DNase I or proteinase K to biofilms demonstrated that eDNA is essential for biofilm formation in most *E. faecium* strains, while proteolysis primarily impacted on biofilm formation of hospital-associated *E. faecium* strains that cluster in clade A1. Secreted antigen A (SagA) was the most abundant protein in biofilms from clade A1 and B *E. faecium* strains, although localization differed between the two groups.

### **Conclusions**

*sagA* is present in all sequenced *E. faecium* strains, with a consistent difference in the repeat region between the clades, which correlated with proteinase K susceptibility in biofilms. This indicates an association between the SagA repeat profile and the localization and contribution of SagA in *E. faecium* biofilms.

**WCAJ DELETION ENHANCES BIOFILM FORMATION IN KLEBSIELLA PNEUMONIAE**

S. Pal<sup>1</sup>, A. Ghosh<sup>1</sup>

<sup>1</sup>*Biotechnology, Indian Institute of Technology Kharagpur, Kharagpur, India*

**Background**

The worldwide occurrence and recent rapid spread of multiresistant strains of *Klebsiella pneumoniae* is of great concern and has generated an urgent need to identify new drug targets. Bacterial adhesion and biofilm formation are important for the establishment of *K. pneumoniae* infections. Elucidation of mechanism of biofilm formation by pathogens is the first step towards the development of novel approaches for the treatment and prevention of biofilm related infections.

**Objectives**

The goal of this study was to gain additional insights into biofilm formation in *K. pneumoniae* MTCC 3384 by using mini-Tn5 transposon mutagenesis.

Disruption of Colanic acid synthesis in *K. pneumoniae* enhances biofilm formation

## Methods

In this study, mini-Tn5 transposon insertion mutants were constructed and screened for their ability to form biofilms on abiotic surfaces by crystal violet staining. It was observed that disruption of *wcaJ* conferred high biofilm forming ability as compared to the parent strain. WcaJ is the initiating enzyme of colanic acid synthesis which loads the first sugar (glucose-1-P) on the lipid carrier undecaprenyl diphosphate. Its absence rendered the mutant defective in colanic acid, resulting in non-mucoid colonies. From the Calcofluor (binds cellulose) binding studies, it was evident that  $\Delta wcaJ$  mutant does not produce much exopolysaccharide, thereby facilitating cell-cell interactions leading to the formation of closely packed structures. In addition, complementation of *wcaJ* *in trans* fully restored the wild type phenotype that confirms the observed effect of *wcaJ* on biofilm formation of *K. pneumoniae*.

## Conclusions

Colanic acid expression in *K. pneumoniae* inhibits its cellular attachment to the substratum and biofilm formation, contradicting earlier studies that polysaccharides enhance biofilms in related species.

**FEMS-1420**

**SALT STRESS INDUCES BIOFILM FORMATION IN CLOSTRIDIUM LJUNGDAHLII.**

J. Philips<sup>1</sup>, K. Rabaey<sup>1</sup>, D.R. Lovley<sup>2</sup>, M. Vargas<sup>3</sup>

<sup>1</sup>Labmet, Ghent University, Ghent, Belgium

<sup>2</sup>Microbiology Department, University of Massachusetts MA, Amherst, USA

<sup>3</sup>Biology Department, College of the Holy Cross, Worcester MA, USA

**Background**

*Clostridium ljungdahlii* is a homoacetogen capable of producing organic commodities from carbon dioxide using electrical energy provided by an electrode, i.e. microbial electrosynthesis. The efficiency of this process likely depends on the biofilm formation on the electrode. So far, however, only limited attachment to electrodes has been obtained with *C. ljungdahlii*, while biofilm formation by *C. ljungdahlii* has not yet been reported.

**Objectives**

The presented work investigated whether adapted growth conditions can induce *C. ljungdahlii* biofilms and characterized the obtained attachment.

**Methods**

*C. ljungdahlii* was grown in 6-well plates using a tryptone containing medium. Different stress conditions (salt, antibiotic, temperature) were tested and biofilm formation was quantified using a crystal violet assay. The addition of NaCl (200 mM) most significantly induced biofilm formation, i.e. after 3 days the attachment was two order of magnitudes higher than in the control. Confocal laser scanning microscopy showed viable,  $45 \pm 5$   $\mu\text{m}$  thick biofilms, while without the addition of salt only a single cell layer (5  $\mu\text{m}$ ) was observed. Furthermore, a  $15 \pm 5$   $\mu\text{m}$  thick biofilm was obtained on a vertically placed piece of graphite, simulating an electrode, by adding NaCl to the medium. RNA sequence data of *C. ljungdahlii* grown with and without the NaCl addition are currently being analyzed to explore the genes involved in biofilm formation.

**Conclusions**

This work is the first to demonstrate biofilms in *C. ljungdahlii* and suggests that salt-induced biofilms of *C. ljungdahlii* should be tested for their microbial electrosynthesis potential.

**Biofilms**

**CHARACTERIZATION OF XANA MUTANT OF THE XANTHOMONAS CITRI  
SUBSP. CITRI**

S.C. Picchi<sup>1</sup>, M.A. Takita<sup>1</sup>, M.A. Machado<sup>1</sup>, A.A. de Souza<sup>1</sup>

<sup>1</sup>Biotechnology Laboratory, IAC – Centro de Citricultura - Sylvio Moreira,  
Cordeirópolis, Brazil

**Background**

*Xanthomonas citri* subsp. *citri* is the causal agent of citrus canker disease. This bacteria is able to form biofilm in vitro and on leave surface. The ability to form biofilm is important to citrus canker development, because it implicates to survival of bacteria on leaf surface of host plants, when it is sprayed on the plant. Cells in biofilm are embedded in a matrix composed for extracellular polysaccharide (EPS) and other proteins. In *Xanthomonas campestris*, the gene *xanA* is required for the synthesis of the exopolysaccharide xanthan, but participation of *xanA* in biofilm formation process was not evaluated in *Xanthomonas citri*.

**Objectives**

To characterize the function of *xanA* (XAC3579) in relation to adhesion, biofilm formation, motility, and epiphytic behavior of *X. citri* on leaves.

**Methods**

We realized assays for analysis of biofilm formation and adhesion in abiotic and biotic surface, EPS quantification, sliding and swimming motility to compare the mutant XAC3579 tn5 and *Xanthomonas citri* wild type.

**Conclusions**

The reduction of xanthan produced reduced the adherence and also the swimming and sliding motility. The presence of the xanthan was required for mature biofilm development on sweet orange leaf surfaces. This reduction can decrease the *Xcc* pathogenicity.

**FEMS-0503**

**PROTEOMICS ANALYSIS IDENTIFIES PROTEINS ASSOCIATED WITH CURCUMIN-TREATED *HELICOBACTER PYLORI* BIOFILM**

P. Ratthawongjirakul<sup>1</sup>, N. Chaichanawongsaroj<sup>1</sup>

<sup>1</sup>*Transfusion Medicine and Clinical Microbiology, Chulalongkorn University, Bangkok, Thailand*

**Background**

*Helicobacter pylori* is an important human pathogen, which is implicated as etiologic agent of peptic ulcer, chronic gastritis and gastric cancer. Recently, *H. pylori* is shown to have ability to form biofilm both *in vitro* and *in vivo*. Biofilm formation enables the bacterium to survive in adverse environments, to persist in patients causing chronic infection and confers enhanced resistance to antibiotics. Curcumin (diferuloylmethane), a natural compound found in turmeric, has been demonstrated for broad chemotherapeutic properties. We have previously reported that curcumin inhibits biofilm formation of *H. pylori* but its impact at a molecular level is unclear.

**Objectives**

This study was established to identify proteins involved in anti-biofilm activity of curcumin in *H. pylori* biofilm using proteomics analysis.

**Methods**

Biofilm of *H. pylori* ATCC43504 was established by pellicle assay. Two-dimensional gel electrophoresis (2-DIGE) and matrix-assisted laser desorption/ionization-time-of-flight (MALDI-TOF) were performed in order to investigate the difference in protein profile expression between curcumin-treated and -untreated *H. pylori* biofilms.

**Conclusions**

There were total 28 expressed proteins identified here. Eighteen proteins were regulated in both curcumin-treated and -untreated *H. pylori* biofilms. Proteins with decreased expression following exposure to 1/4 MIC of curcumin were associated with carbohydrate and nitrogen metabolisms, chemotaxis and motility, and electron transport. However, several chaperon proteins were up-regulated in response to a presence of curcumin. These data reveal a probable mechanism of curcumin that inhibit biofilm formation of *H. pylori*. Further studies need to be investigated in order to develop curcumin as a potential alternative medicine for treatment of *H. pylori* infections.

FEMS-1966

Biofilms

**NOVEL METHODS FOR THE ASSESSMENT OF MARINE ANTI-BIOFILM TECHNOLOGIES.**

M. Salta<sup>1</sup>, J.A. Wharton<sup>2</sup>, S. Dennington<sup>2</sup>

<sup>1</sup>Biology, University of Portsmouth, Portsmouth, United Kingdom

<sup>2</sup>Engineering Sciences, University of Southampton, Southampton, United Kingdom

**Background**

**Marine biofilms, mainly comprised of bacteria and diatoms, are now recognized to be a significant issue for a wide range of engineered structures such as ship hulls, energy systems, sensors, and oil/gas pipe lines. Biofilms constitute a major component of the overall marine growth on ship hulls and may lead to a 14 % increase in ship fuel costs and to an up to 18 % fuel consumption penalties. The scientific community is now placing significant effort towards the creation of environmentally benign surfaces with anti-biofilm capacity. However, there is significant gap in screening assays that test the bacterial/surface interface during initial attachment for anti-biofilm technologies while dynamic testing is often overlooked.**

**Objectives**

**In this work a range of bioassays have been developed to directly test bacterial attachment and biofilm growth on experimental anti-biofilm**

**surfaces, under both static and hydrodynamic conditions.**

#### **Methods**

**Following screening of several compounds for anti-biofilm efficacy, juglone (MIC at 5ppm) was chosen to act as model inhibitory agent, which was then successfully incorporated into a coating system and illustrated good anti-biofilm capacity. Novel microfluidic devices were developed for the assessment of bacterial attachments and biofilm formation in the presence and absence of juglone under hydrodynamic conditions. Juglone inhibited biofilm formation and following nucleic acid staining, toxicity against *Cobetia marina* was evident. This was not clear during the static assays.**

#### **Conclusions**

**The developed bioassays illustrated promising reproducibility and greater relevance for anti-biofilm technologies. New microfluidic approaches have been employed to reveal differences in results when comparing static vs. dynamic testing.**

## FEMS-2800

Satokari<sup>4</sup>, J. Sandholm<sup>5</sup>, P. Siljamäki<sup>2</sup>, T. Alatossava<sup>1</sup>, P. Vuorela<sup>3</sup>, P. Varmanen<sup>1</sup>

<sup>1</sup>Department of Food and Environmental Sciences

<sup>2</sup>Proteomics Unit/Institute of Biotechnology

<sup>3</sup>Faculty of Pharmacy

<sup>4</sup>Veterinary Biosciences, University of Helsinki, Finland

<sup>5</sup>Cell Imaging Core, Turku Centre for Biotechnology, Finland

**Background.** Biofilm formation is the preferred growth mode and survival strategy of several bacteria for improving adaptation and viability under hostile conditions. For mucosal and health-promoting bacteria the biofilm formation is likely to play an important role in colonization and immunostimulation. We have previously shown that the probiotic paradigm *Lactobacillus rhamnosus* GG displays a high number of adhesive and immunostimulatory moonlighting proteins at the cell surface, and that surface-bound proteins are important mediators of biofilm formation of this strain.

**Objectives.** The aim of this study was to explore the effect of fourteen different fermentable carbohydrates on the biofilm formation of *L. rhamnosus* GG, and to uncover their impact on the surface protein/antigen composition and the adhesive properties of the strain during biofilm and planktonic growth.

**Methods.** Biofilm formation was assessed using the standardized polystyrene microtiter plate assay, and the viability and structure of selected biofilms were evaluated with LIVE/DEAD staining coupled with confocal microscopy analyses. Surface-associated proteins and antigens were identified and analyzed using in-house proteome and immunoproteome methods. Selected biofilm and planktonic cultures were further tested for their adhesion activities in vitro.

**Conclusions.** This study indicated that carbohydrate source plays a significant role in the protein-mediated biofilm formation and the antigenicity of the biofilm cells. We also show that moonlighting proteins are the major protein components of the biofilm matrix, and that certain carbohydrates affected the adhesion properties of biofilm cells.

## **FEMS-1307**

### **Biofilms**

#### **HIGH-THROUGHPUT SCREENING OF BIOFILM FORMATION BY AUTOMATED FLUORESCENCE MICROSCOPY**

*J. Schiebel<sup>1</sup>, A. Böhm<sup>1</sup>, J. Nitschke<sup>1</sup>, J. Weinreich<sup>1</sup>, S. Rödiger<sup>1</sup>, P. Schierack<sup>1</sup>*

*<sup>1</sup>Biotechnologie, BTU Cottbus-Senftenberg, Senftenberg, Germany*

#### **Background**

Biofilms are communities of microorganisms which live in a self-produced matrix of extracellular polymeric substances. Their infections are hard to treat due to their resistance to immune defense and antibiotics. Therefore it is important to develop tools to investigate biofilms for therapy improvement or to find new antimicrobial substances.

#### **Objectives**

The aim of this work is to establish a method for the fully automated large-scale screening of biofilms which could be used for examining the ability of biofilm formation of bacteria under different culture conditions and most importantly for determining the effects of different antibiotics and antimicrobial substances.

#### **Methods**

We enhanced our previous published VideoScan technology, which is based on fully automated fluorescence microscopy to perform high-throughput screening of biofilms. VideoScan enables the analysis of multiplex assays such as microbead or cell-based assays [Rödiger et al. 2013; Frömmel et al. 2013]. We use a 96 well plate format for the formation of biofilms, which are stained with Live/Dead staining followed by a VideoScan analysis. This analysis represents a two-step evaluation realized by our software and image processing. In the first step overview pictures of biofilms are taken and in a second step, a fine-grained analysis of the biofilm, bacteria are counted in different z-stacks of the biofilm.

#### **Conclusions**

With our VideoScan technology it is possible to study biofilms in a fully automated large-scale screening. In a next step a large panel of commensal and pathogenic *E. coli* strains will be screened for biofilm formation under different growth conditions and presence of biofilm-associated genes.

**FEMS-1608**

**Biofilms**

## **CURCUMIN DERIVATIVES AS INHIBITORS OF BIOFILM FORMATION IN GRAM POSITIVE AND GRAM NEGATIVE BACTERIA**

D. Schillaci<sup>1</sup>, S. Cascioferro<sup>1</sup>, M.G. Cusimano<sup>1</sup>, A. Leonchiks<sup>2</sup>, M. Vitale<sup>3</sup>

<sup>1</sup>STEBICEF, University of Palermo, Palermo, Italy

<sup>2</sup>BMC, Latvian Biomedical Research and Study Centre, Riga, Latvia

<sup>3</sup>ISZ, Istituto Zooprofilattico Sperimentale della Sicilia, Sicilia, Italy

### **Background**

The development of alternative strategy to conventional antibiotics in the struggle against pathogens and antibiotic resistance is a topical issue. The interference with the adhesion, the first stage of pathogenic process, can modulate virulence mechanisms like colonization, invasion of host tissues and biofilm formation. The curcumin can inhibit the adhesion of both Gram positive and Gram negative pathogenic strains and different mechanisms can be involved (inhibition of sortase A, Quorum-sensing interference, binding to curli, etc.).

### **Objectives**

To obtain novel agents against pathogenic bacteria, targeting virulence mechanisms and biofilm formation (anti-virulence agents).

### **Methods**

In this study, we synthesized a group of molecules derivatives of curcumin, and the inhibition of biofilm formation was evaluated at a screening concentration of 7.5 µg/ml against reference staphylococcal strains *S.aureus* ATCC 29213, 25923, 6238, *S.epidermidis* RP62A, and Gram negative reference strains *E.coli* ATCC 10536 and *P.aeruginosa* ATCC 15442. The activity as sortase A inhibitors was also screened in a high throughput assay by using the standard Dabcyl-QALPETGEE-Edans fluorescence resonance energy transfer (FRET)-peptide substrate for measurement of enzyme activity.

### **Conclusions**

Some curcumin derived compounds resulted effective at lower concentration to prevent biofilm formation than the curcumin. The discovery of novel agents that target virulence mechanisms and biofilm formation offers new potential therapeutic strategies to treat chronic bacterial infections. They can act either alone or in combination with current antibiotics and could significantly impact on overcoming the problem of antibiotic resistance, which is recognized by WHO as one of the most important global challenges of our time.

**FEMS-2479**

**Biofilms**

## **UNRAVELING EROSION DYNAMICS: MICROBIAL STABILIZATION OF FINE SEDIMENTS**

H. Schmidt<sup>1</sup>, M. Thom<sup>1</sup>, S. Wieprecht<sup>1</sup>, S.U. Gerbersdorf<sup>1</sup>

<sup>1</sup>*Dept. of Hydraulic Engineering and Water Resources Management,  
Institute for Modelling Hydraulic and Environmental Systems, Stuttgart, Germany*

### **Background**

During the formation of aquatic biofilms microbes produce extracellular polymeric substances (EPSs) inter alia to attach to the sediment. Thus, sediment grains can be glued together and thereby are granted a significantly increased resistance versus erosive forces - a phenomenon called biostabilization.

### **Objectives**

This process constitutes an essential ecosystem function (e.g. detainment of contaminated fine sediments in rivers) but is currently barely addresses in lotic waters. In our current DFG project engineers and biologists work together to elucidate the fundamental principles of biostabilization.

### **Methods**

Straight flume mesocosm experiments were run at different seasons and under varied boundary conditions to investigate the effect of biotic and abiotic factors upon biofilm development and resulting biostabilization. Besides biofilms' stabilization capacity (adhesiveness and erosion resistance) biochemical and biological features (e.g. microbial biomass, EPS production and microbial community composition) were investigated.

### **Conclusions**

A general temporal increasing stabilizing effect could be detected - one of the first scientific proofs for this process in lotic waters. Furthermore, a strong effect of season and environment upon biofilm development and stabilizing capacity was detected, e.g. a significant maximum during spring but a minimum under minimal illumination. Besides the possible role of EPS protein content as proxy for biofilm stability the importance of successional processes were revealed: especially mutual adaption of algae and bacteria (e.g. expressed by the development of dynamics or functional organization within the bacterial community) is apparently a driving factor.

**Biofilms**

**CONFOCAL LASER SCANNING MICROSCOPY OF BIOFILMS OF EDNA-FORMING BACTERIA GROWN IN A CONTINUOUS FLOW BIOFILM REACTOR**

A. Schuster<sup>1</sup>, U. Szewzyk<sup>1</sup>

<sup>1</sup>*FG Umweltmikrobiologie, TU Berlin, Berlin, Germany*

**Background**

Recent studies show that extracellular DNA is a major component of the EPS (extracellular polymeric substances) in biofilms and it was found to have widespread importance in biofilm formation. However, detailed knowledge about how it promotes biofilm formation and how it influences biofilm morphology is just starting to emerge (1).

The  $\gamma$ -Proteobacterium F8 was isolated from the South Saskatchewan River in Canada. It was found to produce huge amounts of extracellular DNA forming a filamentous network when grown on agar plates containing FBM medium (2, 3).

**Objectives**

The aim of this study was to examine this phenomenon for the first time under continuous flow conditions in a biofilm reactor.

**Methods**

F8 was grown under controlled conditions in a continuous flow biofilm reactor and eDNA-production as well as biofilm morphology was monitored over time. Cells and EPS components were visualized by differential staining with various fluorescent dyes and confocal laser scanning microscopy (CLSM).

**Conclusions**

F8 cells attached to glass slides and showed biofilm formation from day 1 on. Filamentous eDNA could be detected by staining with Syto 9 and Propidium Iodide, but not with DAPI. Results so far indicate that eDNA is emerging from living cells.

**PSEUDOMONAS AERUGINOSA THAT COLONIZED BURN PATIENTS HAS HIGH CAPACITY TO FORM BIOFILM**

K.C.F.A. Silva<sup>1</sup>, G. Deutsch<sup>1</sup>, M. Calomino<sup>1</sup>, P.V. Silva<sup>1</sup>, G.R. Paula<sup>1</sup>, S.R. Castilho<sup>2</sup>, L.M. Esper<sup>3</sup>, L.A. Teixeira<sup>1</sup>

<sup>1</sup>Department of Pharmaceutical Technology, Universidade Federal Fluminense, Niterói, Brazil

<sup>2</sup>Department of Pharmaceutical Administration, Universidade Federal Fluminense, Niterói, Brazil

<sup>3</sup>Department of Bromatology, Universidade Federal Fluminense, Niterói, Brazil

**Background**

In burn patients, *Pseudomonas aeruginosa* can lead to a great variety of systemic infections with higher mortality rate. In addition, treatment of *P. aeruginosa* infections is a serious medical challenge because these bacteria are associated to high resistance to antibiotics and ability to form biofilms, becoming a serious problem in burn wound center (BWC).

**Objectives**

The aim of this study was to investigate the antibiotic resistance and biofilm formation from 35 *P. aeruginosa* collected from wound burn patients and on the surface of the bath tank where balneotherapy was performed.

**Methods**

The antibiotic resistance was carried out by disk diffusion method, following CLSI guidelines and the evaluation of biofilm formation was achieved through microtiter plate assay incubated for 24h. Genotypic characteristics of these strains were determined by Pulsed-field gel electrophoresis (PFGE).

**Conclusions**

It was observed that the clone A, the most prevalent and presents in wound patients and on the surface of the bath tank, had a high capacity to form biofilm. These strains also showed resistance to drugs as ceftazidime, aztreonam, gentamicin, ciprofloxacin and even meropenem. We believed that this clone which is more able to accumulate drug resistance mechanisms and to form biofilm has greater conditions to adapt and to persist in the BWC.

**MICRO-DIVERSITY OF ANAMMOX BACTERIA IN NITRITATION-ANAMMOX BIOFILMS**

C. Suarez<sup>1</sup>, F. Persson<sup>2</sup>, M. Hermansson<sup>1</sup>

<sup>1</sup>*Department of Chemistry & Molecular Biology, University of Gothenburg, Gothenburg, Sweden*

<sup>2</sup>*Department of Civil and Environmental Engineering, Chalmers University of Technology, Gothenburg, Sweden*

**Background**

An emerging technology for nitrogen removal in wastewater is the Anammox process. However questions about the stability of the process remain. It is generally believed that a higher diversity can increase ecosystem stability. Coexistence of two anammox species in a Moving Bed Biofilm Reactor (MBBR) was observed in a previous study (Persson et al. 2014).

**Objectives**

We studied if coexistence of different anammox populations is common in nitrification-anammox MBBRs.

Figure 1: Different anammox populations (detected by different FISH anammox probes) coexisting in biofilms from two different MBBRs. Scale bar 20µm. A) Red: AMX820 probe, Yellow: Ban162 and AMX820. B) Red: Bfu613, Green: Ban162.

**Methods**

Anammox micro-diversity was assessed with automated ribosomal intergenic spacer analysis (ARISA) using a nested PCR approach, and fluorescence in situ hybridization (FISH). Four pilot MBBRs at two different pilot wastewater treatment plants in Sweden with different running conditions and one full-scale integrated fixed-film activated sludge reactor (IFAS) were studied.

**Conclusions**

Preliminary ARISA results suggest that nitrification-anammox MBBRs usually harbor more than one anammox population and FISH from two MBBRs confirmed this (Figure 1). Possible explanations include presence of biofilm microenvironments and temporal variations in environmental conditions such as influent composition. However, one MBBR operated at the challenging conditions of low nitrogen concentrations and at low temperature (13°C) was dominated by a single species.

### **Background**

Patients with medical indwelling devices (e.g. urinary catheters) are prone to acquiring infections caused by biofilm forming pathogens colonizing catheter surfaces. Catheter associated urinary tract infections (CAUTI) are among the most frequent ones. One of the polymers widely used for making urinary catheters is polydimethylsiloxane (PDMS) due to its favorable biocompatibility properties.

### **Objectives**

In order to decrease the risk of infection, an antimicrobial enzyme, namely cellobiose dehydrogenase (CDH) was successfully grafted onto PDMS surface.

### **Methods**

The system is based on the ability of CDH to use oxygen as electron acceptor and different oligosaccharides (e.g. cellobiose) as electron donors to produce H<sub>2</sub>O<sub>2</sub>. Several approaches of immobilizing CDH on PDMS surface were exploited including surface activation using oxygen plasma followed by covalent linkage of CDH. The success of the immobilization process was monitored by analyzing the change in the functional groups on the surfaces by FTIR measurements as well as measuring the ability of grafted CDH to produce H<sub>2</sub>O<sub>2</sub>. Antimicrobial activity of the immobilized enzyme was assessed against *S. aureus* by quantifying the amount of viable cells and total biomass formed on the enzyme treated sheets compared to the control.

### **Conclusions**

CDH was successfully immobilized on the surface of PDMS as evidenced by H<sub>2</sub>O<sub>2</sub> production in the presence of cellobiose. The modified surface showed up to 70% reduction of microbial growth as compared to the untreated control. The CDH modified PDMS catheters could help to prevent current problems of microbial colonization and multidrug resistant bacteria associated with catheters.

**ENHANCED FLOC FORMING MUTANTS OF RHODOVULUM SULFIDOPHILUM  
OBTAINED BY UV MUTAGENESIS**

S. Umekage<sup>1</sup>, A. Noda<sup>1</sup>, Y. Kikuchi<sup>2</sup>

<sup>1</sup>*Environmental & Life Sciences, Toyohashi University of Technology, Toyohashi,  
Japan*

<sup>2</sup>*Advanced Science and Engineering, Waseda University, Tokyo, Japan*

**Background**

A marine photosynthetic bacterium, *Rhodovulum sulfidophilum*, produces nucleic acids extracellularly<sup>1</sup>). Interestingly, the nucleic acids thus produced outside cells are utilized as a sticky glue to make bacterial self-aggregates called “floc” in nutritionally poor medium conditions such as on the sea bottom where the bacterium was originally isolated. However, what gene regulates its flocculation or why this bacterium makes a floc under nutritionally stringent conditions is still unclear.

**Objectives**

Our objectives are to establish UV mutagenesis in *Rhodovulum sulfidophilum* and to obtain UV mutagenic clones showing aberrant flocculation behavior even in rich medium conditions where the bacterium usually doesn't make an obvious floc.

**Methods**

*Rhodovulum sulfidophilum* DSM 1374<sup>T</sup> was exposed to UVC (254 nm) irradiation and UV mutagenesis was induced. After UVC irradiation, rifampicin-resistant mutants were collected and these flocculation behaviors were examined.

**Conclusions**

UV mutagenesis in *Rhodovulum sulfidophilum* DSM 1374<sup>T</sup> was established and 107 rifampicin-resistant mutants were obtained. Two out of the obtained clones showed strong flocculating behavior even in nutritionally rich medium conditions and these flocculation ratios were approximately 40% and 60%, respectively, whereas that of wild type was ca. 20%.

## **MUTUAL INFLUENCE OF *S. EPIDERMIDIS* AND *S. AUREUS* ON GENE EXPRESSION IN DUAL SPECIES BIOFILMS**

I. Vandecandelaere<sup>1</sup>, F. Van Nieuwerburgh<sup>2</sup>, D. Deforce<sup>2</sup>, H.J. Nelis<sup>1</sup>, T. Coenye<sup>1</sup>

<sup>1</sup>Laboratory of Pharmaceutical Microbiology, Ghent University, Ghent, Belgium

<sup>2</sup>Laboratory of Pharmaceutical Biotechnology, Ghent University, Ghent, Belgium

### **Background**

*S. aureus* and *S. epidermidis* are two important nosocomial pathogens which can interact in biofilms (e.g. *S. epidermidis* inhibits *S. aureus* biofilm formation by producing proteases).

### **Objectives**

To study the mutual effect of *S. epidermidis* and *S. aureus* on gene expression in dual species biofilms.

### **Methods**

RNA-Seq was performed on single and dual species biofilms and the results were confirmed by the appropriate phenotypic tests.

### **Conclusions**

In dual species biofilms, *S. epidermidis* genes encoding resistance to erythromycin, oxacillin and tobramycin were upregulated and when biofilms were treated with these antibiotics, we observed that more *S. epidermidis* cells survived oxacillin treatment in dual species biofilms than in single species biofilms.

Urease genes of *S. aureus* were downregulated in dual species biofilms and an urease assay confirmed that there was more urease activity in *S. aureus* single species biofilms compared to dual species biofilms. Literature data described a link between urease activity and pH and we also observed that the pH of *S. aureus* single species biofilms was lower than the pH of dual species and *S. epidermidis* single species biofilms. Metabolic activity results in acid production and RNA-Seq data showed there was less expression, in dual species biofilms, of *S. aureus* genes encoding proteins involved in metabolic processes. Viability assays showed that there were more metabolically active cells in *S. aureus* biofilms compared to dual species and *S. epidermidis* single species biofilms.

Altogether, our results show that *S. epidermidis* has an inhibitory effect on the metabolic activity of *S. aureus* in dual species biofilms.

**ANTI-BIOFILM EFFECT OF RED RASPBERRY FRUIT JUICE ON  
PSEUDOMONAS AERUGINOSA BIOFILM**

V. Gusman<sup>1</sup>, Z. Jelesic<sup>1</sup>, D. Medic<sup>1</sup>, Z. Strajin<sup>2</sup>

<sup>1</sup>Microbiology,

Institute of Public Health of Vojvodina/ Medical Faculty University of Novi Sad,  
Novi Sad, Serbia

<sup>2</sup>Information Technology, Institute of Public Health of Vojvodina, Novi Sad, Serbia

**Background**

Bacterial cells in biofilm are more resistant to wide range of disinfectants than free living cells, and finding an appropriate agent against them is demanding task.

Environment is certainly the source of many products which have anti-biofilm effects, but they have not been proven, yet.

**Objectives**

To investigate the anti-biofilm effect of 100% pure red raspberry fruit juice on *Pseudomonas aeruginosa* biofilm formation.

**Methods**

Minimal inhibitory concentration of red raspberry fruit juice was evaluated by dilution method, and its anti-biofilm effect was tested in microtiter plate using crystal violet staining according to modified technique by Stepanovic.

**Conclusions**

Out of 30 tested strong-adherent *Pseudomonas aeruginosa* isolates, after treating with red raspberry fruit juice, 19 (73.3%) isolates were poorly adherent, while 8 (26.7%) had no adherence ability.

This study confirmed the great potential of red raspberry fruit juice as anti-biofilm agent for preventing microbial colonization, but it is necessary to discover the exact biochemically active ingredient against biofilm formation.

Università degli Studi di Milano, Milano, Italy*

**Background**

Many of the world's most precious artworks are made of stone. Their irreversible deterioration due to biological attack is a worldwide concern. Microorganisms colonize outdoor lithic surfaces and develop into biofilms at the interface solid/air (subaerial biofilms, SABs), which, in turn might cause aesthetic, chemical and physical decay. Although it has been estimated that at least 99% of the world's microbial biomass exists in biofilms, the role and behavior of microorganisms within the biofilm matrix and their complex interactions with the external environment is still unknown.

**Objectives**

This work provides a pioneering and multidisciplinary research to investigate the behavior of microorganisms within the biofilm matrix for sorting out time-spatial relationships and to elucidate microorganism-EPS, inter-organism, biofilm-atmosphere and biofilm-stone interactions.

**Methods**

This work spans sophisticated molecular, chemical, physical and data modeling techniques and it is approached from two complementary angles:

1- Lab-scale study to delineate specific transcriptional responses of mono- and multi-species biofilms as well as the biofilm-stone interactions under controlled environmental conditions.

2- Real heritage case studies to investigate the shifts in the microbial community structure and function under different environmental conditions. Through comparing phylogenetic and functional diversity under different environmental scenarios, we

provide evidence that any intuition gained from the lab-scale experiments is relevant to true environmental biofilms.

## **Conclusions**

The findings obtained so far will contribute to better understand the complexity of all the interactions encountered within SAB communities, and how these interactions may influence the biofilm outcome and the biodeterioration of the stone materials under different environmental conditions.

## **BIOLOGICAL FUNCTIONS AND CELLULAR LOCATION OF COLLAGEN-LIKE PROTEINS IN BACILLUS AMYLOLIQUEFACIENS**

R. Wang<sup>1</sup>, X. Zhao<sup>1</sup>, Y. Wang<sup>2</sup>

<sup>1</sup>*Division of Ecology and Agriculture,*

*Cold and Arid Regions Environmental and Engineering Research Institute CAS, Lanzhou, China*

<sup>2</sup>*Key Laboratory of Desert and Desertification,*

*Cold and Arid Regions Environmental and Engineering Research Institute CAS, Lanzhou, China*

### **Background**

Bacterial collagen-like proteins (CLPs) have been identified in a broad range of pathogen bacteria and it is important to biofilm formation and bacterial adhesion to host cells. Some bacterial CLP-encoding genes (clps) have also been found in non-human pathogenic strains such as *B. cereus* and *B. amyloliquefaciens*, which are types of plant-growth promoting rhizobacteria (PGPR).

### **Objectives**

To elucidate the role of CLPs playing in the interaction between PGPR with plant host, the biological functions and cellular location have to explore.

### **Methods**

CLP-encoding genes ClpA, ClpB, ClpC, and ClpD in strain FZB42, were inactivated separately by Site-Directed Mutagenesis. Scanning electron microscopy (SEM) and hydrophobicity value detection were used to assess the morphologic bacterial cell shape and cell surface architecture. Immune gold labeling was used to indicate the location of CLPs on the cells. The bacterial flagella morphology observed by transmission electron microscopy (TEM).

### **Conclusions**

Comparing with wild type strain, clps mutant strains showed differently on phynotypes of bacterial colony shape, cell autoaggregation, biofilm formation, as well as adhesion to surface of abiotic materials or the roots of *Arabidopsis thaliana*. Immune gold labeling shown CLPs located in the outer layer of the bacterial cell, including the cell wall, outer membrane, flagella, or other associated structures. In addition, the bacterial flagella appeared fewer, scattered and bent for clps mutant strains. Above

results indicate that the bacterial out layer located CLPs are closely involved in cell shape development, biofilm formation, and bacteria-plant interaction.

<sup>3</sup>*Departments of Chemical and Structural Engineering, Delft University of Technology, Delft, Netherlands*

<sup>4</sup>*Center for Microbial Communities, Aalborg University, Aalborg, Denmark*

**Background**

Environmental biotechnology systems using aerobic granular sludge (AGS) are becoming new standards for intensified wastewater treatment. AGS originates from self-aggregation of activated sludge microorganisms into mobile biofilm structures under operational selection pressures. Extracellular polymeric substances (EPS) such as alginate-like exopolysaccharides (ALE) play an important structural role by supporting microbial encapsulation in a gel matrix.

**Objectives**

The complex microbiome of AGS was studied using a systems biology approach. Investigations targeted bacterial phylotypes carrying genetic and metabolic potential for ALE biosynthesis. Such correlation analysis will enable to elucidate molecular mechanisms underlying granular biofilm formation.

**Methods**

A 98-L pilot sequencing-batch reactor was operated for granulation and nitrogen removal from domestic wastewater. Evolution of particle size distribution and EPS polysaccharide and protein fractions were determined by laser diffraction, phenol-sulfuric acid, and folin-phenol methods, respectively. AGS from full-scale system was subjected to physicochemical characterization of ALE. Bacterial populations and genetic signatures related to ALE biosynthesis are currently prospected from pilot and full scales using phylogenetic and metagenomic profiling.

**Conclusions**

Over 3 months of operation granulation displayed gradual increase in the fraction and mean diameter of granular biofilms from 5 to 60% and 50 to 300  $\mu\text{m}$ , respectively. The polysaccharide-to-protein ratio increased concomitantly from 0.4 (m/m) in activated sludge flocs to 0.8 and 1.0 in nitrifying and denitrifying granules, respectively. Lyophilized granules from full-scale plant contained 15% of ALE, i.e. twice higher than typically measured in flocs. Correlating these physicochemical gradients to phylogenetic structure and genomic signatures will allow for fundamental understanding of the granulation phenomenon and its temporal triggering.

**INFLUENCE OF COPPER CHLORIDE AND COPPER SULFATE ON BIOFILM FORMATION OF TWO STAPHYLOCOCCUS AUREUS STRAINS**

J. Schmitz<sup>1</sup>, G.E. Zarfel<sup>2</sup>, C. Kittinger<sup>2</sup>, A. Paulitsch-Fuchs<sup>1</sup>

<sup>1</sup>Department of Microbiology, Wetsus, Leeuwarden, Netherlands

<sup>2</sup>Institute of Hygiene Microbiology and Environmental Medicine,  
Medical University of Graz, Graz, Austria

**Background**

Biofilms pose a way to overcome toxic influences like antibiotics and metal ions. As the number of multiresistant bacteria increases (e.g. *Staphylococcus aureus*) steadily, metals (copper, silver) celebrate their renaissance/revival for many purposes in health care facilities. Not much is known about the tolerance against these heavy metals.

**Objectives**

The known positive effect of the heavy metal tolerance of formed biofilms implicates that there could be a regulatory effect of copper ions on the formation and maturation of biofilms. Previous studies on this matter present inconclusive data, pointing in both directions.

**Methods**

The influence of different CuCl<sub>2</sub> and CuSO<sub>4</sub> concentrations (0.5 – 5 mM) on the formation of biofilms of two *S. aureus* strains as well as on already formed biofilms was tested in a multi well plate assay. Protein and polysaccharide concentrations were quantified and biofilm growth was measured after 48h and 96h.

**Conclusions**

If grown in copper containing solutions the both strains used showed a different behavior. One strain was inhibited at higher copper concentrations (> 2.5 mM), the other strain presented an increased EPS production at the same level. Both, CuCl<sub>2</sub> and CuSO<sub>4</sub>, did not show an inhibitory effect on already formed biofilms of both strains. Interestingly lower concentrations (<3 mM) revealed a biofilm promoting effect. Further studies with more strains are needed to be certain which influence copper has on biofilms and their formation as apparently the strains show different behavior.

**Biofilms**

## **DEVELOPMENT OF BIOFILM MATRIX AND CELL-CELL COHESION IN RHIZOBIUM LEGUMINOSARUM**

*P.L. Abdian<sup>1</sup>, D.M. Russo<sup>1</sup>, N. Vozza<sup>1</sup>, D. Alonso<sup>1</sup>, J. Caramelo<sup>1</sup>, C. von Bilderling<sup>2</sup>, L. Pietrasanta<sup>2</sup>, J. Allan Downie<sup>3</sup>, A. Zorreguieta<sup>1</sup>*

<sup>1</sup>*IIBBA CONICET, Fundación Instituto Leloir, Buenos Aires, Argentina*

<sup>2</sup>*University of Buenos Aires, Centro de Microscopías Avanzadas, Buenos Aires, Argentina*

<sup>3</sup>*John Innes Centre, Norwich, UK*

### **Background**

Biofilm formation is important for rhizobia to colonize several environmental niches. Within the microcolonies developed by *Rhizobium leguminosarum*, rhizobial cells interact tightly through lateral and polar connections forming compact aggregates. These microcolonies are surrounded by a biofilm matrix, whose main component is the acidic exopolysaccharide (EPS). In addition, the PrsDE secretion system has been implicated in biofilm formation. This system is responsible for the secretion of Rap proteins that share one or two Ra/CHDL (cadherin-like-) domains.

### **Objectives**

We aimed to explore the role of Rap(s) and other surface factors in biofilm development.

### **Methods**

RapA was analyzed by biophysical and biochemical approaches. Functional studies were assessed by mutagenesis and gene overexpression.

### **Conclusions**

We showed that RapA, which consists of two Ra/CHDL domains, is a unipolar calcium dependent lectin that specifically binds the EPS. RapA overexpression enhanced biofilm formation and expanded the distance between cells. In line with these observations, we showed that high levels of RapA secretion increases capsular polysaccharide (CPS) formation, which is structurally and genetically related with the EPS. We propose that RapA and the other Rap proteins, which are predicted to harbor one or two EPS/CPS-binding domains, play some role remodeling the biofilm matrix structure. Exploring the role of another important surface polysaccharide, the lipopolysaccharide (LPS), we found that the O-chain core region of the LPS is crucial for cell-cell cohesion. Mutants defective in the O-chain core moiety developed

biofilms with an altered three-dimensional structure. Further studies are required to give insight into the interplay between the biofilm matrix components and Rap(s).

## **BIOFILM ACCUMULATION AT DIFFERENT WATER TREATMENT STAGES**

M. Zunabovic<sup>1</sup>, L. Richard<sup>1</sup>, E. Mayr<sup>1</sup>, R. Allabashi<sup>1</sup>, D. Rosner<sup>1</sup>, G. Lindner<sup>1</sup>,  
R. Perfler<sup>1</sup>

<sup>1</sup>*Department of Water Atmosphere Environment,  
Institute of Sanitary Engineering and Water Pollution Control, Vienna, Austria*

### **Background**

Biofilms are microbial communities and highly relevant for water quality. In principle biofilms may affect human health in drinking water reservoirs and distribution systems hindering the efficient operation of these systems. Also they may also pose a health risk due the presence of pathogenic bacteria such as *Legionella pneumophila* and *Escherichia coli*.

### **Objectives**

The aim of this study was to describe biofilms accumulating within controlled pilot plant after different treatment steps. The use of various methodological approaches should describe biofilms and the associated water phases in order to assess potential factors associated with human health risks.

### **Methods**

In total 6 biofilm samples were collected from the PE-X pipes of the pilot drinking water treatment plant.

The plant is designed for the drinking water treatment of a small rural community located in Upper-Austria (193 inhabitants in 2014; average daily water consumption: 20 m<sup>3</sup>). The treatment has 4 successive steps: 1) oxygen enrichment (using pressurized air) 2) biological nitrification, 3) rapid sand filtration and 4) UV-disinfection.

Biofilms were characterized by chemical (TOC, DOC, heavy metals), microbiological (HPC, flow cytometry) and molecular biological (16S rRNA gene sequencing) and microscopic methodologies.

### **Conclusions**

The multi-parametric approach applied in this study has shown valuable results with good correlations among chemical and microbiological characterization. The activity of biofilms (viability) could be described by flow cytometry and fluorescent microscopy. Phylogenetic analysis of sequenced culturable fractions revealed differing diversities in the microbial communities.

**Novel strategies for prokaryotes to rapidly transition from planktonic cells to life in a biofilm**

R. Esquivel<sup>1</sup>

<sup>1</sup>*Department of Biology, University of Pennsylvania, Philadelphia, PA 19104, USA*

Biofilms are diverse microbial communities, bound by a matrix of extracellular polymeric substances, that allow cells to survive a variety of stressful, potentially lethal, conditions. To successfully avoid exposure to such toxic conditions, cells must transition rapidly from planktonic to sessile state, requiring quick acting regulatory mechanisms that can both inhibit motility and promote adhesion. We previously showed that the evolutionarily conserved type IV pili (TFP) are crucial for surface adhesion and microcolony formation in the model archaeon *Haloferax volcanii*. We also demonstrated that six conserved *H. volcanii* pilus subunits, the pilins PilA1-6, are involved in the regulation of flagella-dependent motility. Additionally, a subset of these pilins promotes microcolony formation, while at least two of the remaining pilins inhibit it. Recent studies suggest that pilin glycosylation catalyzed by the glycosyltransferase, AglB, plays an important role in the regulation of microcolony formation. Consistent with the pilins required for microcolony formation (PilA5 and PilA6) not being glycosylated, and the remaining pilins requiring glycosylation to function properly, we have shown that a  $\Delta$ aglB strain forms microcolonies. Stress adversely affects AglB-dependent glycosylation, which is also required for flagella-dependent motility, hence inhibiting motility and promoting microcolony formation. Consistent with this we found that under low salt conditions *H. volcanii* is not motile and readily forms microcolonies. This differential post-translational modification that allows *H. volcanii* cells to respond quickly to changes in the environment that result in conditions favorable to sessile cells and biofilm formation rather than motile planktonic cells may be broadly conserved across prokaryotes.

**Biotechnology and industrial microbiology**

**The potential of halophilic microorganisms to convert waste glycerol to valuable compounds: glycerol carbonate (GlyC) and glycidol (GlyD)**

*S. Neagu<sup>1</sup>, A. Gheorghe<sup>2</sup>, M. Săndulescu<sup>2</sup>, M. Enache<sup>1</sup>*

*<sup>1</sup>Institute of Biology Bucharest of the Romanian Academy, Bucharest, Romania*

*<sup>2</sup>University of Bucharest, Bucharest, Romania*

Background: Waste glycerol is the most important by-product in the production of biodiesel from biomass. As a direct consequence, waste glycerol (unpurified) was produced in quantities which soon will exceed current market demands leading to serious environmental problem by its storage.

Objectives: This work enlarges the application area for waste glycerol, proposing its usage as raw material in the production of glycerol derivatives (e.g. GlyC, GlyD and polyglycidol). Thus, alternative solutions for the storage problem of waste glycerol that can generate negative effects on the environment are developed. GlyC, GlyD and polyglycidol represent products of interest for fine chemical industry. Thus, GlyC is used as solvent for cosmetics and in medicine, while GlyD and polyglycerols appear as synthesis intermediates of plastics and resins in the polymer industry, but also in the pharmaceutical and cosmetic industries.

Methods: The products of interest were revealed in culture media using GC-MS and GC-FID techniques. Also, the polyglycidol products were evaluated (Mw, Mn and PI) based on GPC technique.

Conclusions: Preliminary results revealed ability of various moderately halophilic bacteria isolated from saline and hypersaline environments from Romania to convert waste glycerol to GlyC and GlyD. Lipase enzyme is responsible for GlyC production, while lipase and decarboxilase mixture convert the glycerol to GlyD. Polymerization of GlyD is performed under basic conditions.

**FEMS-2821**

**Biotechnology and industrial microbiology**

**Production of antimicrobial and anticancer substances by *Bacillus pumilus* SG-32 and *Bacillus firmus* P1-1 isolated from oil reservoirs in Brazil.**

*T.R. Sila<sup>1</sup>, M.A. Foglio<sup>1</sup>, V.M. Oliveira<sup>1</sup>*

*<sup>1</sup>Microbial Resources Division, Research Center for Chemistry, Biology and Agriculture (CPQBA), University of Campinas (UNICAMP), Campinas, Brazil.*

**BACKGROUND:** Thirty strains isolated from Brazilian oil reservoirs were tested against each other for the production of antimicrobial substances. Two strains of *Bacillus*, *B. pumilus* SG-32 and *B. firmus* P1-1 were selected due to their ability to inhibit more than 60% of the strains tested. These strains were also investigated for cytotoxic activity against human cancer cell lineages.

**METHODS:** The screening of antimicrobial substances was performed by the agar diffusion method described for Rosado and Seldin (1993). Thirty strains previously isolated from oil reservoirs in Campos Basin (RJ, Brazil) were tested against each other for antimicrobial production. Two selected strains were grown in Marine Broth for 72 hours at 40°C to increase cell biomass. Anticancer screening was performed against nine different types of human cancer cell lineages.

**RESULTS:** Among the thirty strains tested, three of them (two strains of *Bacillus pumilus*, SG-30 and SG-32, and one strain of *Bacillus firmus*, P1-1) were able to inhibit more than 60% of the bacterial strains under study. Strains P1-1 and SG-32 were chosen for subsequent cytotoxic activity assay against human cancer cells. Strain P1-1 presented better effect than the positive control doxorubicin against colon and breast cell cancer lineages. Strain SG-32 was not as efficient as the positive control; nevertheless five types of cancer cell lineage were inhibited.

**CONCLUSIONS:** Three different *Bacillus* strains from Brazilian oil reservoirs were able to produce antimicrobial substances, two of them with significant activity against cancer cell lineages, showing potential for further clinical trials.

**Biotechnology and industrial microbiology**

**SAFETY EVALUATION OF SOME COMMERCIAL SKIN COSMETICS USING A GENETICALLY MODIFIED ACINETOBACTER BIOLUMINESCENT BIOREPORTER DF4/PUTK2**

G. Abu-Elreesh<sup>1</sup>, A. Kamal<sup>1</sup>, S. Zaki<sup>1</sup>, D. Abd-El-Haleem<sup>1</sup>

<sup>1</sup>*Environmental biotechnology department,  
Genetic Engineering and Biotechnology Research Institute City of Scientific Res,  
Alexandria, Egypt*

**Background**

Human skin is suffering from continued use of cosmetics, which may leads to ecosystem disruptions of useful skin microbiota. Therefore, a need to ensure its safety-in-use is important. Despite, microbiological assays employed to determine the lowest cosmetic concentration gave the lowest microbial contamination level during usage; toxicity assay must be performed first.

**Objectives**

In the present work, the Bioreporter DF4/PUTK2 was employed to assess the toxicity of eight local commercial cosmetic products. DF4/PUTK2 is a genetically modified strain belongs to the genus *Acinetobacter* that widely spread in nature and skin microbiota. Previously, DF4/PUTk2 was successfully employed to assess toxicity of phenolics and heavy metals.

**Methods**

Present results indicated that among the eight tested cosmetics, the Bioreporter was directly sensitive in order of decreasing sensitivity to aftershave balm, skin-refining toner, moisturizing cream and purifying cream with bioluminescence inhibition percent (BI%) equal to 64%, 58%, 50% and 30% respectively, Followed by eye makeup remover and sun cream with (BI%) equal to about 15% but after exposure time 300 and 700 min respectively. However, no decrease for bioluminescence with eye color powder and color trend – fresh foundation was observed. Also, the effect of exposure time on bioluminescence was tested. It was noticed that the cosmetics that expected to remain for a long time on skin seems most toxics.

**Conclusions**

In conclusion, the Bioreporter DF4/PUTK2 can be used to assay the toxicity of cosmetics and it is candidate to be a prescreening and quality control tool to pre-select the most toxic cosmetic for further chemical analysis.

**FEMS-0528**

**Biotechnology and industrial microbiology**

**INCREASING SOLUBLE EXPRESSION OF ALPHA-LUFFIN RIBOSOME  
INACTIVATING PROTEIN BY ENBASE FED-BATCH CULTURE**

*F. Barkhordari<sup>1</sup>, Y. Garoosi<sup>1</sup>, F. Davami<sup>1</sup>*

*<sup>1</sup>Biotechnology, Pasteur Institute of Iran, Tehran, Iran*

**Background**

Considering the undeniable advantages of natural toxins from RIP family to produce anticancer immune-conjugates, well optimized recombinant expression of this category of proteins is of importance regarding industrial aspects. One of the proposed cellular mechanisms involved in EnBase fed-batch mode of cultivation is the change in protein expression via ribosomal manipulation. However, this system has not been applied to cytotoxic proteins.

**Objectives**

For the first time here, the expression profile of  $\alpha$ -luffin, a ribosome inactivation protein (RIP) with an innate toxicity, was optimized in EnBase system. In fed-batch fermentation mode, the early incubation time was preferable at 30° C culture temperature whereas at 25° C the extended protein synthesis period (12 and 24h post induction) resulted in higher amount of soluble recombinant protein.

## Methods

Mature  $\alpha$ -luffin encoding cDNA was synthesized and subcloned into pET28a under the control of T7 promoter fused to the 6-HIS tag. The *E. coli* expression procedure was compared in traditional batch and newly developed fed batch; EnBase® Flo system at 25° C and 30°C incubation temperatures.

## Conclusions

As the first study investigating the efficacy of EnBase fed-batch mode for the production of a toxic protein ( $\alpha$ -luffin) it is concluded that in spite of the efficacy of this system in producing higher soluble protein ratios compared to batch cultivation growth rate, incubation temperature and time need to be optimized so as to cover innate cytotoxicity. The optimized condition proposed here is promising in terms of large scale soluble production of  $\alpha$ -luffin without the need for refolding.

## **ANALYSIS OF TRANSCUTANEOUS DELIVERY OF TAT-BONT/A(1-448) FUSION PROTEIN AS THERAPEUTIC AGENT**

P. Saffarian<sup>1</sup>, S.H. Najar Peerayeh<sup>1</sup>, J. Aman<sup>2</sup>, A.A. Imani Foolad<sup>2</sup>,  
H. Sedighian Rad<sup>2</sup>

<sup>1</sup>Medical Bacteriology, Tarbiat Modares University, Tehran, Iran

<sup>2</sup>Applied Microbiology, Baghiyatallah University of Medical Science, Tehran, Iran

### **Background**

Botulinum neurotoxin type A (BoNT/A) composed of three domain. One catalytic domain and one binding domain which are linked together by a translocation domain. In recent years, BoNT/A was used as a therapeutic agent for treatment some abnormal muscle contractions such as strabismus, blepharospasm, spasmodic or face wrinkles caused by ageing process. The injection of this drug causes some undesirable side effects such as irritation, pain, bleeding at the point of injection. Cell penetrating cationic peptides (CPPs) are three to 30 peptide residues which freely pass through cell membranes. Tat peptide is a CPP which is a favorite way to transduction of biological macromolecules (peptides, proteins or nucleotides) into cells.

### **Objectives**

In this study, Tat<sub>(47-57)</sub> peptide directly fused to catalytic domain of BoNT/A. The penetration of this recombinant protein was analyzed *in vitro*.

### **Methods**

A genetic construct containing Tat gene sequence, residues 47-57, was fused with that of BoNT/A (residues 1-448) and cloned into a bacterial host for further expression. Obtained fusion protein, was purified and transferred into a 6 well plate seeded by HeLa cell line and was incubated at 37°C for 1 to 2 h. Transduction of protein was further analyzed by western blot.

### **Conclusions**

Results showed that Tat<sub>(47-57)</sub> peptide can carry the BoNT/A<sub>(1-448)</sub> into HeLa cell line in comparison to BoNT/A<sub>(1-448)</sub> as control. Cell transduction was time dependent (protein band in western blot after 2 h was thicker than 1 h). CPPs are promising tools for

transferring different type of drugs directly into intact skin for therapeutic purposes through a non-invasive way.

## **CAN *S. CEREVISIAE* PRODUCE BIO-BASED POLYMERS FROM PENTOSE SUGARS?**

D.J. Portugal Nunes<sup>1</sup>, A.M. de las Heras<sup>1</sup>, A.G. Sandström<sup>1</sup>, M.F. Gorwa-Grauslund<sup>1</sup>

<sup>1</sup>Division of Applied Microbiology, Lund University, Lund, Sweden

### **Background**

A sustainable future necessitates an urgent transition from petroleum-based industries towards the production of bio-based bulk chemicals from renewable feedstock [1]. The bio-based polymers, such as polyhydroxyalkanoates (PHAs), can be produced from monomeric sugars. Poly-3-D-hydroxybutyrate (PHB) is one of the most studied PHAs and is a promising biopolymer produced naturally by several bacterial species [2]. In parallel, xylose is the main pentose sugar present in lignocellulosic biomass (LCB), which is considered the cheapest carbon source on earth [3]. Thus, LCB is a potential substrate for the bio-based production of bulk chemicals such as PHB.

### **Objectives**

In this work, the capacity of recombinant *Saccharomyces cerevisiae* to produce PHB using pentose sugars (xylose) as the main carbon source was evaluated.

### **Methods**

Engineered *S. cerevisiae* strains, capable of pentose utilization were transformed with the PHB pathway genes from the natural and well-characterized PHB-producer *Cupriavidus necator*. The two host strains carried genes for xylose utilization from the yeast *Scheffersomyces stipitis*, but two variants of the xylose reductase (XR) with different NADH/NADPH preference ratio were tested [4]. The resulting strains were evaluated for their PHB-production capacity.

### **Conclusions**

The production of PHB from xylose-rich medium was achieved using *S. cerevisiae*. The highest PHB yield (g/g xylose) was achieved with the strains carrying the mutated *S. stipitis* XR with a higher NADH/NADPH preference, highlighting the importance of redox balancing for PHB production.

<sup>2</sup>Department of Biology and Ecology, University of Ostrava, Ostrava, Czech Republic

<sup>3</sup>Nanotechnology Centre, Technical University Ostrava, Ostrava, Czech Republic

### **Background**

Biodegradation potential of fungi for removal of dyes from textile wastewater has been established and applied in aerated reactors.

### **Objectives**

The aim was to compare dye-degradation efficiency of a newly isolated *Trametes suaveolens* strain with different fungal species in RDR. Reactive RB19 (C.I.61200) and disperse DB3 (C.I.61505) dyes were used.

### **Methods**

2-L RDR (6 disks, rotation speed 2 rpm, air flow 50L.h<sup>-1</sup>) was used for dye decolorization (50mg.L<sup>-1</sup>) in malt extract-glucose medium at 22°C. Decolorization was measured spectrophotometrically and the end-products by GC/MS. Bacterial luminiscence test, plant growth tests and Ames test were used to measure acute toxicity and genotoxicity.

### **Conclusions**

Using batch mode, RB19 decolorization rates were: *Irpex lacteus* > *T. suaveolens* > *Pleurotus ostreatus*. When continuous mode was used, the dye degradation capacity of *T. suaveolens* was 2-fold compared to the batch mode. Majority of the degradation products were aromatic alcohols. No genotoxicity was detected after degradation. The acute toxicity measured with *Vibrio fischeri*, *Sinapis alba* and *Lemna minor* decreased 1.2-, 2.7- and 1.6-fold, respectively. The results demonstrated the efficiency of fungal RDR for removal of textile anthraquinone dyes.

## **SULFATE-REDUCING BACTERIA AS WHOLE-CELL BIOCATALYSTS FOR HYDROGEN PRODUCTION**

M. Martins<sup>1</sup>, C. Mourato<sup>1</sup>, I. A.C.Pereira<sup>1</sup>

<sup>1</sup>Universidade Nova de Lisboa,

Instituto de Tecnologia Química e Biológica António Xavier, Oeiras, Portugal

### **Background**

Sulfate-reducing bacteria (SRB) are a major group of environmental bacteria with important biotechnological applications in waste water treatment and bioremediation. These organisms have an extremely high hydrogenase activity and in natural habitats where sulfate is limited they produce hydrogen fermentatively and grow syntrophically with other organisms. However, their potential as H<sub>2</sub>-producers has been poorly investigated.

### **Objectives**

Given the high number of hydrogenases present in SRB genomes [1] we explored the potential of the model strain *Desulfovibrio vulgaris* Hildenborough for H<sub>2</sub> production from three substrates (lactate, ethanol, formate).

### **Methods**

Among the substrates tested the highest H<sub>2</sub> production was observed from formate [2]. Formate has emerged recently as an environmental friendly storage of H<sub>2</sub> that can be easily transported and has relatively low toxicity. Therefore a lab-scale H<sub>2</sub> production process with gas sparging was designed to evaluate the potential of SRB as biocatalysts for formate-driven H<sub>2</sub> production [3].

### **Conclusions**

By optimizing the operation conditions of bioreactor such as temperature, gas flow rate and cell load, a high H<sub>2</sub> production rate was obtained. In addition, a high specific hydrogen production rate and 100% efficiency of substrate conversion were achieved, demonstrating the high potential of SRB for H<sub>2</sub> production from formate [3]. Our studies reveal that SRB can be used as an efficient biocatalyst for the conversion of formate to hydrogen.

## **INVESTIGATING MICROALGAE AS A BIOTECH PLATFORM FOR HIGH-VALUE OILS**

R. Young<sup>1</sup>, S. Vonlanthen<sup>1</sup>, S. Purton<sup>1</sup>

<sup>1</sup>*Structural and Molecular Biology Darwin Building, University College London, London, United Kingdom*

### **Background**

Natural oils are found in a diverse range of products such as soaps, paints, cosmetics, antibacterial treatments and nutritional supplements (fish oils).

### **Objectives**

As part of a consortium with the University of Cambridge, the University of Aberdeen and Rothamsted Research we aim to establish the microalga *Nannochloropsis gaditana* as a platform for the production of these commercially important oils. The advantages of microalgae as a production platform include low media costs, lack of toxins and fast growth rates; *N. gaditana* was chosen due to its naturally high lipid content.

### **Methods**

The production of bespoke lipids will require a combination of metabolic modelling and nuclear genetic engineering to introduce or knock out specific elongase and desaturase genes. To test the genetic tractability of this species, two constructs were prepared that contained *ble-gfp* or *ble-HA* fusion genes; the *ble* marker encodes resistance to zeocin. *N. gaditana* was transformed by electroporation and colonies were selected on media containing zeocin. All of the colonies tested carried the expected transgene and accumulated Ble-GFP or Ble-HA fusion protein, as detected by western blotting.

### **Conclusions**

The *N. gaditana* nuclear genome is amenable to genetic transformation by random integration, paving the way for our metabolic engineering studies over the next three years.

## **MALIC ACID PRODUCTION FROM RENEWABLE SOURCES BY ASPERGILLUS ORYZAE**

S. Doersam<sup>1</sup>, C. Sylдатk<sup>1</sup>, K. Ochsenreither<sup>1</sup>

<sup>1</sup>*Technical Biology, Karlsruhe Institute of Technology, Karlsruhe, Germany*

### **Background**

L-malic acid is a C4 dicarboxylic organic acid and considered as a promising chemical building block. It can be applied as food preservative and acidulant, in rust removal because of its chelator properties and as polymerization starter unit due to its bifunctionality. Up to now it is produced chemically from crude oil via maleic anhydride. The mould *Aspergillus oryzae* produces malic acid in large quantities from glucose and other carbon sources. The microbial production of organic acids from renewable sources has the potential to be a sustainable alternative to petroleum and to reduce greenhouse gases as CO<sub>2</sub> fixation is involved in microbial biosynthesis.

### **Objectives**

The potential of malic acid production from renewable resources is evaluated. Therefore, different carbon sources based on lignocellulosic biomass, e.g. fractions of pyrolysis oil and hemicellulosic sugars, are tested.

### **Methods**

*A. oryzae* was cultivated in preculture medium in shaking flasks for 17 hours. Due to nitrogen limitation and an excess of glucose in the production medium the fungus started to produce malic acid. A bioreactor process using glucose as carbon source was already established<sup>1</sup> and used as basis for the evaluation of alternative carbon sources. Organic acid concentration was measured by HPLC.

### **Conclusions**

*A. oryzae* proved to be a promising natural host for malic acid production with the potential to use several renewable carbon sources.

**EXPLORING NON-CONVENTIONAL YEAST SPECIES AS SOURCE FOR  
ENHANCING ANAEROBIC XYLOSE FERMENTATION IN METABOLIC  
ENGINEERED *SACCHAROMYCES CEREVISIAE***

A. Muñoz de las Heras<sup>1</sup>, R.M. Cadete<sup>2</sup>, A.G. Sandström<sup>1</sup>, C. Ferreira<sup>3</sup>, M. Gorwa-Grauslund<sup>1</sup>, C.A. Rosa<sup>2</sup>, C. Fonseca<sup>3</sup>

<sup>1</sup>Applied Microbiology, Lund University, Lund, Sweden

<sup>2</sup>Microbiologia, Universidade Federal de Minas Gerais, Belo Horizonte, Brazil

<sup>3</sup>Unidade de Bioenergia, Laboratório Nacional de Energia e Geologia, Lisboa, Portugal

**Background**

Efficient conversion of xylose, a five-carbon sugar present in significant amounts in the hemicellulose fractions of a wide range of lignocellulosic biomass, is required for the development of second generation bioethanol. Xylose is not naturally consumed by the baker's yeast, *Saccharomyces cerevisiae*, therefore heterologous pathways has to be introduced by genetic engineering. This includes introducing one of the two known pathways for the conversion of xylose to xylulose: xylose isomerase (XI) or xylose reductase and xylitol dehydrogenase (XR-XDH). In most xylose-consuming fungal species, XR is an enzyme that uses NADPH as the dominant co-factor for xylose reduction to xylitol. It has been observed that *S. cerevisiae* strains harbouring XR variants with an increased preference for NADH have more efficient xylose fermentation, therefore exploring the diversity of XRs with different co-factor affinity is essential.

**Objectives**

In this work we have evaluated the xylose utilisation under anaerobic conditions from two constructed *S. cerevisiae* strains carrying different varieties of xylose reductases.

**Methods**

The strain TMB3422, carrying a mutated version of the *Scheffersomyces stipitis* XR gene and a constructed strain, carrying a novel XR gene from a fermenting yeast species that was isolated from rotting-wood samples, were compared for characteristics under fermentative conditions.

**Conclusions**

The best xylose fermenting yeast strain analysed revealed significantly higher ethanol yield and productivity, as well as lower xylitol yield under anaerobic conditions, which represents an advance towards the efficient fermentation of lignocellulosic hydrolysates to ethanol.

**SOLID WASTE FROM COFFEE PROCESS FOR  $\beta$ -GLUCOSIDASE PRODUCTION BY *BACILLUS SUBTILIS***

C. Silva<sup>1</sup>, M. Dias<sup>1</sup>, M.M. Melo<sup>1</sup>, R.F. Schwan<sup>1</sup>

<sup>1</sup>*Biology, Federal University of Lavras, Lavras, Brazil*

**Background**

The coffee production for the Brazil is a second important *commodity* however the solid and liquid waste during the process is a environmental problem. Some works focus on use these waste to produce organic acids, enzymes and other products

**Objectives**

The aims were optimize the  $\beta$ -glicosidase production for *Bacillus subtilis* in submerged fermentation using coffee pulp as substrate and evaluated the optimize condition culture in bioreactor.

**Methods**

The coffee pulp was dried at 60 °C for 72 h until reaching constant weight. After that, the coffee pulp was ground in Willey mill (1.0 mm). The microorganism used in study was *Bacillus subtilis* CCMA0087 belongs to Culture Colection of Agricultural Microbiology (CCMA) of Federal University of Lavras (Brazil), isolated from Brazilian Cerrado fruit namely Marolo. The enzyme production was done by Response Surface methodology. The media culture was based in Kasana et al. (2008) with modification (%), 0.2 NaNO<sub>3</sub>, 0.1 K<sub>2</sub>HPO<sub>4</sub>, 0.05 MgSO<sub>4</sub>, 0.05 KCl, 0.02 peptone and coffee pulp (0.32 – 3.68) as a carbon source. The  $\beta$ -glucosidase activity as measured by p-nitrophenyl- $\beta$ -D-glucopyranoside (PNPG) as substrate.

**Conclusions**

In bench scale, *Bacillus subtilis* UFLA BCEF1130 show high  $\beta$ -glucosidase production (22.59 UI/mL) at pH 3.64, 36.6 °C and concentration coffee pulp of 36,8 g/L. However, in bioreactor the enzyme production was 2.5 less than bench scale in the same experimental conditions. The work continues to understand the scale up effect over the  $\beta$ -glucosidase production.

<sup>3</sup>R&D, Contipro Group s.r.o., Dolní Dobrouč, Czech Republic

### **Background**

Hyaluronidases (Hz) are enzymes that degrade predominantly hyaluronan (HA). Until recently, three groups of Hz were reported: hyaluronate 4-glycanohydrolases (found in Vertebrates and venom of some insects), endo- $\beta$ -glucuronidases (leeches and crustaceans) and hyaluronan lyases (bacteria). Recently a new group of HA degrading enzymes from Micromycetes belonging to genus *Penicillium* was reported [Bakke M, Kamei J & Obata A., 2011, DOI: <http://dx.doi.org/10.1016/j.febslet.2010.11.021>]. These enzymes hydrolyze  $\beta$ -1,4 glycosidic bonds in HA, similar to Vertebrate Hz, however have different conserved domains. We report discovery of another producer of hyaluronate 4-glycanohydrolase from the Kingdom Fungi, the yeast *Pseudozyma aphidis*.

### **Objectives**

To characterize *P. aphidis* extracellular Hz.

### **Methods**

*P. aphidis* was cultivated in bioreactor Techfors-S with 20 L working volume (Infors AG, Switzerland). The enzyme was isolated from cultural broth filtrate and partially purified by diafiltration on Sartorius Hydra membrane cassette with 10 kDa cut-off and ion-exchange chromatography on DEAE-Sepharose Fast Flow (GE Healthcare). The products of HA enzymatic hydrolysis were analyzed by HPLC and LC-MS. Gel permeation chromatography, SDS-PAGE and Morgan-Elson colorimetric assay were used for enzyme characteristic.

### **Conclusions**

*P. aphidis* produced extracellular enzyme with hyaluronate 4-glycanohydrolase activity. Temperature and pH optima of HA hydrolysis were 45 °C and pH 3.0 respectively. The enzyme didn't hydrolyze neither chondroitin sulphate nor  $\beta$ -(1.3;1.6)-glucan schizophyllan. *P. aphidis* Hz showed high thermal stability that makes advantageous its application for enzymatic production of hyaluronan oligomers.

Asociación de Investigación INBIOTEC Instituto de Biotecnología de León. Avda. Real 1 - Parque Científico de León 24006. [rvicu@unileon.es](mailto:rvicu@unileon.es), León, Spain

**Background**

Feruloyl esterases (FAEs) represent a diverse group of hydrolases catalyzing the cleavage of ester bonds between plant cell wall polysaccharide and phenolic acid. These enzymes are key tools for degradation of plant cell wall and are widely distributed in plants and microorganisms. FAEs release ferulic acid and other aromatic acids from these polymeric structures and have received an increasing interest in biotechnological processes for industrial and medicinal applications.

**Objectives**

In the worldwide market there are not fully purified FAEs or enough enzyme stocks. Discovery of new FAEs with novel properties continues to be an important research area that has increased drastically since 1990. Following this research line (CTM2012-32026 project<sup>1</sup>), genetic engineering techniques to improve the FAEs production in the filamentous fungus *Penicillium chrysogenum* have been applied.

**Methods**

Several transformants, whose production of FAEs is significantly improved with respect to the parental strain, have been obtained. Special interest deserves B13 transformant that multiplies the FAE activity more than 90 times when the substrate of the enzyme is methyl ferulate and over of 14 when the substrate is sugar beet pulp. Furthermore, this FAE activity from the B13 strain was compared with the activity that is present in some commercial enzymes versus synthetic and natural substrates.

**Conclusions**

The analysis of the results revealed that the B13 enzymatic extracts triplicate the FAE activity in comparison with the analyzed commercial enzymes.

<sup>1</sup>The project CTM2012-32026 is funded by Spanish Ministry of Economy and Competitiveness (MINECO) through the Subprogramme for Non-Guided Fundamental Research Projects. 2012.

## **PARAMETERS AFFECTING THE PRODUCTION OF LIPASE ENZYME BY A NEW ISOLATE YEAST.**

*H. Hammamchi<sup>1</sup>, N. Cihangir<sup>1</sup>*

<sup>1</sup>*Biology, Hacettepe University, Ankara, Turkey*

### **Background**

Lipases (E.C.3.1.1.3; tri glycerol acyl hydrolases) are hydrolizer enzymes which catalyze free fat into glycerol and triglycerid. Industrial lipase commonly is provided by external cellular activity from strains of microorganisms. Microbial lipases are produced in liquid phase and its activity is influenced by concentrations of carbon/ nitrogen resources, pH, temperature and metal ions.

### **Objectives**

In this study, fungi as a lipase source, isolated from the village which is located near Eskişehir city. In the production of lipase, environmental conditions and media components are investigated as important parameters.

### **Methods**

Vegetable oils as carbon source, carbohydrate source and nitrogen sources are used for lipase activity investigation. To find the optimal condition, firstly between 3.0 – 9.0 pH and 10 – 40°C several experiments are carried out to detect the effects of these varieants on lipase production.

### **Conclusions**

As a result of several experiments for production of lipase from *Rhodotorula*, the optimal condition is pH 5.0, temperature 30°C, 1% concentration of carbon from olive oil and the best source of nitrogen, the pepton has been considered. As a result of combination of carbon and nitrogen sources with olive oil, the activity of lipase was increased.

**FEMS-0693**

**Biotechnology and industrial microbiology**

**PRODUCTION OF LIPASE ENZYME BY A NOVEL FUNGAL SOURCE,  
TRICHODERMA SP.**

*M.H. Akyil<sup>1</sup>, N. Cihangir<sup>1</sup>*

<sup>1</sup>BIOLOGY, Hacettepe University, Ankara, Turkey

**Background**

The industrial use of enzymes obtained from animals, plants and microorganisms has developed recently and the most important source for enzyme production has been determined as microorganisms. Lipases has a important application areas in industry.

**Objectives**

In this research the lipase enzyme which has a industrial importance was obtained from new fungal source that was isolated from soil. Subsequently it was determinated as *Trichoderma citrinoviride* by the analysis of 18S rRNA sequence.

**Methods**

Lipase activity was determined by titrimetric assay. Optimum conditions were detected for production of lipase.

**Conclusions**

The lipase enzyme by isolated fungi (*Trichoderma citrinoviride*) was extracellular and showed its highest activity on the 4. day of the incubation period. In the production of lipase, culture conditions and media components are investigated as important parameters. Various carbon and nitrogen sources were used for highest lipase activity. Also we detected that pH 5,5 and temperature 30 °C are optimum conditions for lipase production.

<sup>2</sup>Transcriptomics, INBIOTEC (Instituto de Biotecnología de León), León, Spain

<sup>3</sup>Microbiology, Pharmins Ltd, Pushchino, Russia

<sup>4</sup>Microbiology, University of York, York, United Kingdom

<sup>5</sup>Microbiology, Stiftelsen SINTEF, Trondheim, Norway

<sup>6</sup>DSP, Technische Universität Dortmund, Dortmund, Germany

<sup>7</sup>Molecular biology, Gadea Biopharma S.L., León, Spain

#### Background

The project **MySterI** (*Mycobacterial Steroids for Industry*), supported by the ERA-IB 3<sup>rd</sup> joint call, aims at producing high value steroid precursors using a novel bioconversion strategy that will yield a greening process with lower production costs (@MySterI\_ERA\_IB; <http://www.era-ib.net/mysteri-0>). The bioconversion of phytosterols (low cost plant material similar to cholesterol) to desired steroid precursors is performed using engineered fast-growing mycobacteria in a single fermentation step.

#### Objectives

The targeted precursors are: androst-4-ene-3,17-dione (AD), 3 $\beta$ -hydroxyandrost-5-ene-17-one (DHEA) and then 11 $\alpha$ -hydroxyandrost-4-ene-3,17-dione (11- $\alpha$ -OH-AD) and testosterone.

#### Methods

The key points tackled by the Consortium are: i) Genome sequencing and annotation of *Mycobacterium* sp. NRRL B-3805 (AD-producer) to identify key bioconversion genes and to enable 'omics tools; ii) Understanding of phytosterol bioconversion by means of 'omics technologies; iii) Development of the genetic engineering tools for *Mycobacterium* sp. NRRL B-3805; iv) Construction of mycobacterial strains capable of producing 11- $\alpha$ -OH-AD, DHEA and testosterone; v) Designing more efficient and eco-friendly methods of production and downstream processing for the three selected compounds

#### Conclusions

The MySterI pipeline is a top to bottom process that brings together six interdisciplinary research groups from Universities, Research Centres and Industrial companies in 3 different EU member states [Spain (**INBIOTEC**; **Gadea Biopharma**), Germany (**Technische Universität Dortmund**) and UK (**University of York**)], as

well as Norway (**Stiftelsen SINTEF**) and Russia (**Pharmins Ltd.**). Therefore, the MySterI results in progress are: i) novel strains capable of producing three valuable C19-steroid precursors from phytosterol ii) knowledge of the biochemistry of steroid biotransformations iii) optimized fermentation and eco-friendly downstream processes for the single-step production.

<sup>2</sup>Proteomics, INBIOTEC (Instituto de Biotecnología de León), Leon, Spain

<sup>3</sup>Pilot Plant, INBIOTEC (Instituto de Biotecnología de León), Leon, Spain

**Background**

Microbial biotransformation to generate new steroid drugs is a well-established application of industrial biotechnology. Thus, several worldwide enterprises are involved in steroid production (e. g.: Gadea Biopharma SL, Sanofi, Pfizer). Biotransformation can begin with different raw materials, but the mixture of plant sterols (phytosterols) have been the research focus in recent decades. However, the studies to date show that improvements in phytosterols broth culture solubility, product recovery and mainly in microbial strains are needed.

**Objectives**

Optimization of the whole molecular biology methodologies valid for a non-well characterized microbial strain has been carried out on the androstenedione (AD)-producer strain *Mycobacterium* sp. NRRL B-3805. Thus, i) growth conditions; ii) phytosterols solubility analysis; iii) growth titration in dirty media; iv) steroids quantitation by HPLC; v) genomic DNA extraction suitable for genome sequencing; vi) high quality RNA for transcriptomics (RNAseq, microarrays) analyses; as well as vii) secreted protein purification for 2D-DIGE secretome methods have been improved.

**Methods**

An example of successful optimized process is the genome sequencing pipeline defined for *Mycobacterium* sp. NRRL B-3805. This genome sequencing and annotation, as well as the understanding of phytosterols bioconversion by means of 'omics technologies (RNAseq, microarrays, 2D-DIGE) are capital for the ERA-IB 3<sup>rd</sup> joint call supported project MySterI (@MySterI\_ERA\_IB; <http://www.era-ib.net/mysteri-0>).

**Conclusions**

Thus, key bioconversion genes and target genes suitable for the development and use of genetic engineering tools have been defined. This genome was fully sequenced using Ion Torrent and Sanger technologies. It comprises 5,421,338 bp in a circular chromosome with a GC content of 67 %.

**SOLID PHASE EXTRACTION BASED ON THE USE OF HELVELLA CRISPA AS A FUNGAL BIOMASS FOR THE PRECONCENTRATIONS OF PB AND AL BY ICP-OES**

A. Dündar<sup>1</sup>, C. Keskin<sup>2</sup>, E. Kilinc<sup>3</sup>, S. Ozdemir<sup>4</sup>, V. Okumus<sup>4</sup>

<sup>1</sup>Medical Marketing and Promotion Programme, Mardin Artuklu University, Mardin, Turkey

<sup>2</sup>School of Health Department of Nutrition and Dietetics, Mardin Artuklu University, Mardin, Turkey

<sup>3</sup>Medical Laboratory Techniques, Mardin Artuklu University, Mardin, Turkey

<sup>4</sup>Biology, Siirt University, Siirt, Turkey

**Background**

The use of fungal biomass for the preconcentration and separation of traces of heavy metals and some organic materials at trace levels are popular due to the good adsorption properties such as high surface area and high adsorption capacity of the fungus.

**Objectives**

This study describes the biosorption potential of *Helvella crispa* as a sorbent for solid phase extraction (SPE) and preconcentration of Pb<sup>2+</sup> and Al<sup>3+</sup>.

**Methods**

The model solution was passed through the prepared SPE column at an adjusted flow rate with a peristaltic pump. Then, 10.0 mL distilled water was passed through the column. The retained Pb<sup>2+</sup> and Al<sup>3+</sup> on the fungal biomass was then eluted with 5.0 mL of 1.0 mol L<sup>-1</sup> HCl. The concentration of Pb<sup>2+</sup> and Al<sup>3+</sup> in this solution was determined by ICP-OES.

**Conclusions**

The limit of detection (LOD) of Pb and Al was found to be 0.10 ng mL<sup>-1</sup> and 0.03 ng mL<sup>-1</sup>, respectively. The sensitivity of ICP-OES improved 39.8-fold for Pb and 39.5-fold for Al. Linearity was obtained in the concentration range of 1.25–50.0 ng mL<sup>-1</sup> for Pb and 0.5–50.0 ng mL<sup>-1</sup> for Al. The relative standard deviation (RSD) of the method under optimum conditions was lower than 8.4% (n=5) for Pb and Al, which was validated through the analysis of certified reference tea and poplar leaves samples. The biosorption capacity of immobilized *Helvella crispa* for Pb and Al was found to be 31.2 mg g<sup>-1</sup> and 45.7 mg g<sup>-1</sup>, respectively.

**WHICH IS A BETTER APPROACH FOR ENZYME EXPLORATION?: CULTURE-DEPENDENT AND -INDEPENDENT (METAGENOMIC) APPROACHES TO THE SCREENING FOR AROMATIC-DEGRADING ENZYMES.**

H. Suenaga<sup>1</sup>, K. Miyazaki<sup>1</sup>, K. Yaoi<sup>1</sup>

<sup>1</sup>*Bioproduction Research Institute,  
National Institute of Advanced Industrial Science and Technology (AIST), Tsukuba,  
Japan*

**Background**

Although metagenomics is regarded as one of the best approaches for mining enzymes, its superiority over traditional culture-dependent approach is still controversial.

**Objectives**

Therefore, culture-dependent and -independent approaches were used for extensive retrieval of the extradiol dioxygenase (EDO) gene from the environment to investigate the relationship between the EDO genes from isolated bacteria and the metagenomic EDO genes from which they were isolated.

**Methods**

In our previous study, we identified 91 fosmid clones showing EDO enzyme activity using a metagenomic approach (Environ Microbiol 9, 2289-2297, 2007). In the present study, we newly isolated 88 phenol-utilizing bacteria from the same environmental sample and identified four EDO genes from them. Of these, two EDOs had amino acid sequences similar to those reported previously in aromatic-utilizing strains, and one EDO had a sequence almost identical to that of metagenomic EDOs identified in our previous study. Unexpectedly, one EDO showed no similarity to any class I EDOs and was categorized as class II, which has not been found in past any metagenomic approaches. Quantitative polymerase chain reaction (PCR) assay indicated that the low-abundance class II EDO gene can be enriched by culturing approaches.

**Conclusions**

We conclude that the combined use of the two approaches can explore the gene community more extensively than their individual use.

## **ENGINEERING STREPTOMYCES DIASTATOCHROMOGENES 1628 TO INCREASE THE PRODUCTION OF TOYOCAMYCIN**

Z. Ma<sup>1</sup>, L. Tao<sup>1</sup>, X. Xu<sup>1</sup>, Y. Bian<sup>1</sup>, X. Shentu<sup>1</sup>, X. Yu<sup>1</sup>

<sup>1</sup>College of Life Sciences, China Jiliang University, Hangzhou, China

### **Background**

Toyocamycin (TM) is a member of the nucleoside antibiotics. It shows antifungal activity and might be used to treat plant diseases. TM is produced by *Streptomyces diastatochromogenes* 1628 but the production rate is always very low. Recently the gene *toyG* was cloned and its function in TM biosynthesis was reported. However, nothing was known about the influence of *toyG* on TM production.

### **Objectives**

We studied the influence of three genes on TM production. *Vgb*, *frr*, and *toyG* were co-expressed, either in double- or triple-combinations.

### **Methods**

Over-expression of these genes in double or triple leads to great significant increased production of TM in strain *S. diastatochromogenes* 1628. At the end, among all these different strains constructed in this work, the strain *S. diastatochromogenes* 1628-VGF, harboring *vgb*, *frr* and *toyG* that was placed under the control of *PermE*<sup>\*</sup>, respectively, exhibited the largest increase in TM production. Notably, the TM production of *S. diastatochromogenes* 1628-VGF reached the highest level at 831.2 mg/L at 72 h, while TM yield of original strain *S. diastatochromogenes* 1628 at 415.1 mg/L at 84 h.

### **Conclusions**

Based on known knowledge, TM yield produced by engineered strain *S. diastatochromogenes* 1628-VGF was the highest as ever reported. The high-yield, energy-saving strain *S. diastatochromogenes* 1628-VGF constructed in this study shall be beneficial for the industrial production of TM.

**EXPRESSION OF THE CELLULOSOMAL GENE CLUSTER OF CLOSTRIDIUM CELLULOVORANS IN BUTANOL-PRODUCING CLOSTRIDIUM BEIJERINCKII**

A. Hiramatsu<sup>1</sup>, K. Kuroda<sup>2</sup>, M. Ueda<sup>2</sup>, Y. Tamaru<sup>1</sup>, H. Miyake<sup>1</sup>

<sup>1</sup>Department of Life Sciences, Graduate School of Bioresources Mie University, Tsu, Japan

<sup>2</sup>Division of Applied Life Sciences, Graduate School of Agriculture Kyoto University, Kyoto, Japan

**Background**

Biofuel production from cellulosic biomass consists of pretreatment, saccharification, fermentation and distillation. However, production is hindered by the high cost compared with energy crops, such that innovative technologies are required. One approach is consolidated bioprocessing (CBP), in which pretreatment, saccharification, and fermentation are consolidated.

**Objectives**

*Clostridium cellulovorans* 743B, an anaerobic and mesophilic bacterium, produces a large extracellular enzyme complex (cellulosome) that efficiently hydrolyzes cellulosic biomass. The cellulosomal gene cluster of *C. cellulovorans* includes *cbpA*, which encodes a scaffold protein, and seven downstream glycoside hydrolase genes. *Clostridium beijerinckii* NCIMB 8052 cannot produce a cellulosome and does not degrade soft biomass, but instead produces butanol, acetone, and ethanol from mono- and disaccharides. The aim of this study was to express the cellulosome of *C. cellulovorans* in *C. beijerinckii* to obtain a bacterium able to carry out CBP.

**Methods**

The large cellulosomal gene cluster containing the *cbpA* gene was used to transform *C. beijerinckii* by electroporation. Protein-level expression of the gene cluster encoding the scaffold protein CbpA and mannanase A was demonstrated by western blotting. Cellulose and galactomannan activities on polysaccharide substrates were evaluated by Congo red staining.

**Conclusions**

The transformant was shown to be capable of hydrolyzing galactomannan and produced butanol directly. This butanol-producing bacterium provides the basis for the CBP of lignocellulose to biobutanol.

**Biotechnology and industrial microbiology**

## **EFFECTS OF IRON AND MAGNESIUM IONS COMBINATION ON HYDROGEN PHOTOPRODUCTION BY RHODOBACTER SPHAEROIDES**

*L. Gabrielyan*<sup>1</sup>, *A. Trchounian*<sup>1</sup>

<sup>1</sup>*Microbiology & Plants and Microbes Biotechnology, Yerevan State University, Yerevan, Armenia*

### **Background**

Iron and magnesium are essential for growth of photosynthetic bacteria.  $Mg^{2+}$  participates in the structure of photosynthetic electron carriers and pigments.  $Fe^{2+}$  is known as the component of enzymes, involved in bio-hydrogen ( $H_2$ ) production.

### **Objectives**

In this work the effects of metal ions combinations on growth and  $H_2$  photoproduction by *Rhodobacter sphaeroides* MDC6522, isolated from Jermuk mineral springs in Armenia, in compare to single ions effects, were investigated.

### **Methods**

*R. sphaeroides* was cultivated under anaerobic conditions upon illumination in the presence of  $Fe^{2+}$  and  $Mg^{2+}$  various concentrations. The  $H_2$  yield was calculated by the decrease of redox potential, measured by platinum electrode.

### **Conclusions**

The results pointed out the concentration dependent effects of metal ions. *R. sphaeroides* was unable to grow well in the absence of  $Fe^{2+}$  and  $Mg^{2+}$ , which indicates the importance of these ions for bacterial growth. The highest growth rates of *R. sphaeroides* cells were obtained in the presence of 0.08 mM  $Fe^{2+}$  and 5 mM  $Mg^{2+}$ , in compare to control (0.04 mM  $Fe^{2+}$  and 1 mM  $Mg^{2+}$ ). The simultaneous addition of metal ions stimulated bacterial growth rate ~1.2-fold in compare to the single ions. The highest  $H_2$  yields were obtained in the presence of 0.08 mM  $Fe^{2+}$  and 10 mM  $Mg^{2+}$ , which were ~1.5-fold higher than control. However, the  $H_2$  production was increased ~2.5-fold, when two metals were added simultaneously in concentration 0.08 mM  $Fe^{2+}$  and 5 mM  $Mg^{2+}$ . Thus, combinations of metal ions in appropriate concentrations are preferable for  $H_2$  production enhancement in *R. sphaeroides*.

**HIGH-LEVEL EXPRESSION, RAPID ON-COLUMN REFOLDING AND  
PURIFICATION OF RECOMBINANT HUMAN VASCULAR ENDOTHELIAL  
GROWTH FACTOR 165 IN ESCHERICHIA COLI**

A. Salimi<sup>1</sup>, H. Ghasempure<sup>1</sup>

<sup>1</sup>*Biotechnology-Chemical Engineering,  
Science and Research Branch Islamic Azad University, Kermanshah, Iran*

**Background**

Vascular endothelial growth factors (VEGFs) are a family of proteins that promote angiogenesis and participate in a variety of physiological and pathological processes. VEGF165 is the major isoform induced by hypoxia, oncogene mutations, and cytokines such as IL-1, IL-8, and TNF- $\alpha$  and secreted by many cell types. It is a potent angiogenic factor and mitogen that stimulates proliferation, migration, and formation of endothelial cells. Cancerous cells are able to grow and metastasize by VEGF secretion.

**Objectives**

A. PCR screening of the recombinant plasmid pET32a+ ( VEGF165).

B. SDS-PAGE analysis of rhVEGF165 expression in BL21(DE3) cells  
 U: uninduction (-IPTG)  
 I: Induction (+IPTG) restriction sites.

C. The effects of induction time and temperature on soluble and insoluble rhVEGF165 aftr cell disruption  
 I: Insoluble  
 S: Soluble.

D. SDS-PAGE analysis and immunoblot with anti-His-tag antibody .

E. SDS-PAGE analysis of purified rhVEGF165 with On-Column refolding system.

F. SDS-PAGE and Western Blot analysis of purified rhVEGF165 using anti-His-tag antibody.

A recombinant VEGF165 might be used in order to produce an antibody against it and also it could be used as a growth factor in some biological mediums.

## Methods

The RNA was extracted from Hela cell, and then used for cDNA synthesis. The gene encoding human VEGF isoform 165 (hVEGF165) was cloned into the expression vector pET32a (+) to construct a fusion expression plasmid that induced the thioredoxin (Trx) Gene. The expressed protein was purified by affinity chromatography using Ni-NTA resin. High concentration of the recombinant protein obtained from a single-step.

## **Conclusions**

Fusion of VEGF to thioredoxin and careful codon optimization of the eukaryotic sequence could be improved to a high-level insoluble protein expression in comparison to an un-optimized, His-tagged construct. The thioredoxin-fused protein was successfully purified using an on-column Ni-NTA purification procedure. SDS-PAGE and Western Blotting analysis confirmed the desired expression. rhVEGF165 could readily and rapidly purify with on-column Ni-NTA system chromatography.

## ADHESION OF ALKANOTROPHIC ACTINOBACTERIA TO SOLID SURFACES AND HYDROPHOBIC LIQUIDS

*A. Krivoruchko*<sup>1</sup>, *A. Iziumova*<sup>2</sup>, *O. Plekhov*<sup>2</sup>, *I. Korshunova*<sup>1</sup>, *M. Kuyukina*<sup>1</sup>, *I. Ivshina*<sup>1</sup>

<sup>1</sup>Laboratory of Alkanotrophic Microorganisms of the Institute of Ecology and Genetics of Microorganisms UB RAS,

Microbiology and Immunology Department of the Perm State University, Perm, Russia

<sup>2</sup>Laboratory of Physical Basis for Material Integrity,

Institute of Continuous Media Mechanics UB RAS, Perm, Russia

### Background

Mechanisms of adhesion of biotechnologically significant alkanotrophic actinobacteria are poorly studied.

### Objectives

1. To study the adhesion of actinobacteria to a wide range of solid carriers and hydrophobic liquids under various growth conditions. 2. To determine physical–chemical and molecular factors of actinobacterial adhesion. 3. To define adhesion conditions providing the highest catalytic activity of actinobacteria.

**Figure.** Images of monolayer actinobacterial biofilms obtained with an interference microscope (A), an atomic force microscope (B), and an infrared camera (C). Arrows show cells.

### Methods

100 strains from the IEGM Collection of Alkanotrophic Microorganisms (acronym IEGM, WDCM # 768, [www.iegml.ru/iegmlcol](http://www.iegml.ru/iegmlcol)) were used in this study. The substrates for adhesion were polystyrene microplates, technical polymer tissue, industrial wastes (sawdust, poultry feathers, and leather), *n*-alkanes C10–C16, solvents, and different oils. Molecular genetic and biochemical mechanisms of adhesion were studied using targeted and *in vivo* Tn5 mutagenesis, chemical analysis of cell wall, and specific inhibition. Cell morphology, nanomechanical properties, adhesion forces, and distribution of actinobacteria on solid carriers were studied by interference microscopy and combined confocal and laser scanning atomic force microscopy. Thermodynamic data were obtained using infrared thermography.

### Conclusions

Adhesion was shown to be a key mechanism in hydrophobic compound oxidation by

actinobacteria. Involvement of glycolipid biosurfactants, proteins, and cell appendages in adhesion was revealed. Monolayer actinobacterial biofilms with high ( $115 \text{ mg} \cdot \text{l}^{-1} \cdot \text{h}^{-1}$ ) hydrocarbon–oxidizing activities were formed on solid surfaces hydrophobized with glycolipid biosurfactants (Figure). The results obtained could be used to develop biocatalysts for targeted biotransformations and pollutant degradation. The research was supported by the RFBR grant (14-04-96013), the RSF grant (14-14-00643), and the President of the Russian Federation for Leading Scientific Schools' grant (4607.2014.4).

## **BIOTRANSFORMATION OF BETULIN USING RHODOCOCCUS ACTINOBACTERIA**

I. Ivshina<sup>1</sup>, E. Tarasova<sup>1</sup>, V. Grishko<sup>2</sup>

<sup>1</sup>Laboratory of Alkanotrophic Microorganisms of the Institute of Ecology and Genetics of Microorganisms UB RAS,  
Microbiology and Immunology Department of the Perm State University, Perm, Russia

<sup>2</sup>Laboratory of Biologically Active Compounds, Institute of Technical Chemistry, Perm, Russia

### **Background**

Bacterial transformation of triterpenoids (in particular betulin) is an efficient method for single-stage production of biologically active compounds with high regio- and stereoselectivity.

### **Objectives**

1. To demonstrate the possible use of *Rhodococcus* actinobacteria for selective biotransformation of betulin, a pentacyclic lupine-type triterpenoid. 2. To study the interaction mechanisms between rhodococci and betulin, and its biotransformation pathways. 3. To evaluate the possible application of products from bacterial betulin oxidation for subsequent synthesis of biologically active compounds using chemical methods.

### **Methods**

The biological resources of the IEGM Collection of Alkanotrophic Microorganisms (acronym IEGM, WDCM # 768, [www.iegm.ru/iegmcol](http://www.iegm.ru/iegmcol)) were used in this study. Conventional bacteriological methods, including betulin transformation by resting rhodococcal cells were employed. The mechanism of cell interaction with betulin was determined using methods of phase contrast, confocal lazer scanning, and atomic force microcopy. Rhodococcal viability was estimated using a LIVE/DEAD® BacLight™ Bacterial Viability Kit (Invitrogen, USA).

### **Conclusions**

Biotransformation of betulin (0.5 and 3.0 g/l) using *Rhodococcus* actinobacteria was demonstrated for the first time. Betulone was identified as a major metabolite. The optimal conditions for betulin bioconversion by resting cells of *R. rhodochrous* IEGM 66 were selected. Further chemical modifications of betulone resulting from bacterial betulin transformation lead to the formation of 3,4-secobetulone with a marked cytotoxic activity (IC<sub>50</sub> 3.05 мкМ) against melanoma.

The research was supported by the RFBR grant (14-04-96017), and the President of the Russian Federation for Leading Scientific Schools' grant (4607.2014.4).

**COMMERCIALLY IMPORTANT HIGH MOLECULAR WEIGHT DEXTRAN FROM INDIGENOUS WEISSELLA CIBARIA CMGDEX3**

R. Z Ahmed<sup>1</sup>, K. Siddiqui<sup>1</sup>, M. Arman<sup>2</sup>, N. Ahmed<sup>1</sup>

<sup>1</sup>Center for Molecular Genetics, University of Karachi, Karachi, Pakistan

<sup>2</sup>Pharmaceutical Research Center, PCSIR Laboratories Complex, Karachi, Pakistan

**Background**

Extracellular polysaccharides (EPS) of microbial origin are associated with the cell surface or excreted in the extracellular environment. Several food grade microorganisms, including lactic acid bacteria (LAB), synthesize EPS. The synthesis of EPS by LAB has gained remarkable interest because of LAB categorization as safe organisms and vast utilization of synthesized EPS in markets from food to health and industry. Dextran is a polysaccharide composed of D-glucose units which is synthesized by various LAB under appropriate conditions and widely used in several industries including food, pharmaceutical and chemical.

**Objectives**

Present study was designed to isolate LAB capable to synthesize good quality dextran and characterize the synthesized dextran.

**Methods**

In this study five bacterial strains were isolated from different vegetables and fruit samples on the basis of slime production in selected agar medium with 15% sucrose. When those five strains were cultivated in medium for the production and extraction of EPS, the highest crude yield of EPS was obtained from CMGDEX3 which was isolated from cabbage and identified as *Weissella cibaria* by 16S rRNA gene sequencing. EPS extracted from *W. cibaria* CMGDEX3 was purified and analyzed for structure by FTIR, <sup>1</sup>H and <sup>13</sup>C NMR spectroscopy. Molecular weight was determined by gel permeation chromatography.

**Conclusions**

Analysis of EPS demonstrated that *W. cibaria* CMGDEX3 synthesized commercially important linear dextran that predominately had α (1→6) glycosidic linkages with few (3.4%) α (1→3) linked branches. Molecular mass determination showed that it was a high molecular weight dextran of an average > 2,000,000 Daltons.

**SCREENING AND SELECTION OF PROBIOTIC LACTIC ACID BACTERIA  
INHIBITING PATHOGENIC BACTERIA AND VIRUSES**

K. Kim<sup>1</sup>, Y. Shin<sup>2</sup>

<sup>1</sup>*Bioscience & Biotechnology, The University of Suwon, HwaSeong-Si Gyeonggi-do, Korea*

<sup>2</sup>*Center for Bio-Industry, The University of Suwon, HwaSeong-Si Gyeonggi-do, Korea*

**Background**

Probiotic refers to viable, nonpathogenic microorganisms that, when ingested, are able to reach the intestines in sufficient numbers to confer health benefits to the host. Intake of probiotics reduces the amount of pathogens improving thus the intestinal microbial balance of the host and lowering the risk of gastro-intestinal diseases.

**Objectives**

To isolate potential probiotic bacterial strains inhibiting rota- and polio- viruses as well as pathogenic bacteria.

**Methods**

Three thousands bacterial strains isolated from various sources including human milk and fermented foods were screened for potential probiotics inhibiting rota- and polio-viruses as well as pathogenic bacteria such as enterotoxigenic *Escherichia coli*, *Clostridium perfringens*, *Listeria monocytogenes*, *Staphylococcus aureus*, *Salmonella* Typhimurium,. The antibacterial activity of each culture filtrate was determined by agar-diffusion method and the antiviral activity of heat-treated culture broth was examined by reduction of plaque forming unit *in vitro* culture system. The properties of the bacterial strains with particular functions such as adherent ability to enterocyte, tolerances towards gastric juice, bile, and tolerances to heat and cold-dry conditions were further investigated to select strains for probiotic use.

**Conclusions**

One potential lactic acid bacterium with desirable probiotic characteristics as well as the highest anti-viral and anti-bacterial activities was selected and identified as *Lactobacillus plantarum* according to its 16rRNA gene sequence.

**FEMS-0830**

## **OPTIMIZATION OF THE SECRETION OF BACTERIOCINS AND THE BACTERIAL CELL GROWTH OF *GEOBACILLUS* SP. 15 STRAIN**

A. Kaunietis<sup>1</sup>, R. Pranckute<sup>1</sup>, D. Citavicius<sup>1</sup>

<sup>1</sup>*Microbiology and Biotechnology, Vilnius University, Vilnius, Lithuania*

### **Background**

Bacteriocins are natural peptides secreted by variety of bacteria and provide the bacteria with a competitive advantage in their environment, eliminating competitors to gain resources. Bacterocin production may be strongly influenced by growth environment and medium composition. Many different studies have indicated the potential usefulness of bacteriocins in food preservation, veterinary, medicine or as phytosanitary measures for plant protection. To date, only few bacteriocin producing thermophilic bacterial strains of genus *Geobacillus* have been identified. Studies of factors affecting the production of bacteriocins by *Geobacillus* spp. bacteria are relatively scarce.

### **Objectives**

This research was focused on the analysis effect of salts and to establish optimal conditions for bacteriocins production and bacterial cell growth for thermophilic bacteria *Geobacillus* sp. 15 strain.

### **Methods**

*Geobacillus* sp. 15 strain was used as a bacteriocin producer. *Geobacillus stearothermophilus* NUB36187 (BGSC No. 9A11) was selected as the indicator strain for the bacteriocin assay. Nutrient broth (NB) liquid media were chosen for the strain growth and bacteriocin expression monitoring. It were supplemented with salts: KCl, ZnSO<sub>4</sub>, MnSO<sub>4</sub>, CuSO<sub>4</sub>, MgCl<sub>2</sub>, CaCl<sub>2</sub>, NaNO<sub>3</sub>, NaHCO<sub>3</sub>. Bacteriocin activity was detected by agar well diffusion assay.

### **Conclusions**

The greatest influence on bacterial growth was in NB medium with MnSO<sub>4</sub> or with KCl and MgSO<sub>4</sub>. The best bacteriocin expression was achieved in media supplemented with two salts at a time: KCl and MgCl<sub>2</sub>, MnSO<sub>4</sub> and NaHCO<sub>3</sub> or CaCl<sub>2</sub> and ZnSO<sub>4</sub>.

**METABOLIC ENGINEERING OF *C. GLUTAMICUM* THROUGH CONSOLIDATED BIOPROCESSING FOR SUCCINATE PRODUCTION FROM CO<sub>2</sub>-GROWN MICROALGAL BIOMASS AS CARBON SOURCE**

*J. Lee*<sup>1</sup>, *S.J. Sim*<sup>2</sup>, *M. Bott*<sup>3</sup>, *Y. Um*<sup>1</sup>, *H.M. Woo*<sup>1</sup>

<sup>1</sup>*Clean Energy Research Center, Korea Institute of Science and Technology, Seoul, Korea*

<sup>2</sup>*Department of Chemical and Biological engineering, Korea University, Seoul, Korea*

<sup>3</sup>*Institute of Bio- and Geosciences, Forschungszentrum Jülich, Jülich, Germany*

**Background**

This study presents the development of consolidated bioprocessing for succinate production from microalgal biomass using engineered *Corynebacterium glutamicum*.

**Objectives**

Our objective in this study is to develop the *C. glutamicum* strain capable of utilizing starch as carbon source using the synthetic biology-platform and to apply the strain for production of succinate from microalgal biomass as sole carbon source.

**Methods**

We developed the starch-degrading and succinate-producing *C. glutamicum* strains, which produced succinate (0.16 g succinate/g total carbon source) from a mixture of starch and glucose as a model microalgal biomass. Subsequently, the engineered *C. glutamicum* strains were able to produce succinate (0.28 g succinate/g of total sugars) from pretreated microalgal biomass of CO<sub>2</sub>-grown *Chlamydomonas reinhardtii*. For the first time, this work shows succinate production from CO<sub>2</sub> via sequential fermentations of CO<sub>2</sub>-grown microalgae and engineered *C. glutamicum*.

**Conclusions**

In conclusions, consolidated bioprocessing based on microalgal biomass could be useful to promote variety of biorefineries.

<sup>1</sup>microbiology, A. Mira University, Bejaia, Algeria

<sup>2</sup>microbiology, university of Reims, Bejaia, Algeria

<sup>3</sup>microbiology, university of Béjaia, Bejaia, Algeria

**Background**

The impetus for research in the field of bioseparation has been sparked by the difficulty and complexity in the downstream processing of biological products. Indeed, 50% to 90% of the production cost for a typical biological products resides in the purification strategy. There is a need for efficient and economical large scale bioseparation techniques which will achieve high purity and high recovery, while maintaining the biological activity of the molecule. One such purification technique which meets these criteria involves the partitioning of biomolecules between two immiscible phases in an aqueous system (ATPS).

**Objectives**

The purification of xylanase from the strain *Jonesia denitrificans* BN13 using ATPS an efficient and economical bioseparation technique.

**Methods**

The Production of xylanases is carried out in 500ml of a liquid medium containing birchwood xylan. In each ATPS, PEG 1000 is added to a mixture consisting of dipotassium phosphate, sodium chloride and the culture medium inoculated with the strain *Jonesia denitrificans*. The concentration of PEG 1000 was varied : 8 to 16 % and the NaCl percentages are also varied from 2 to 4% while maintaining the other parameters constant, the xylanolytic activity was detected by zymogram coupled to SDS-PAGE.

**Conclusions**

The results showed that the best ATPS for purification of xylanases is composed of PEG 1000 at 8.33%, 13.14 % of  $K_2HPO_4$  , 1.62% NaCl at pH 7. We obtained a yield of 96.62 %, a partition coefficient of 86.66 and a purification factor of 2.9. The zymogram showed that the activity is mainly detected in the top phase.

<sup>7</sup>SLSG, University of Palermo, Palermo, Italy

**Background**

The filamentous actinobacterium *Microbispora* sp. ATCC-PTA-5024 produces the lantibiotic NAI-107 (Maffioli *et al.*, 2014), which is effective against multidrug-resistant Gram-positive pathogens (Jabés *et al.*, 2011).

In actinomycetes, the biosynthesis of antibiotics is generally elicited as a physiological response controlled by a complex regulatory network involving global regulators, playing pleiotropic roles, and pathway-specific regulators, which activate the biosynthesis of biologically active molecules (Bibb, 2005).

**Objectives**

The integration of bioinformatic tools and holistic technologies has allowed the development of consolidated strategies to manage huge amounts of complex molecular information on gene expression and biochemical capabilities deriving from 'omic' investigations, ultimately leading to novel approaches to explore microbial physiology. In the perspective of using *Microbispora* strains for the industrial synthesis of a NAI-107, insights on the molecular physiology of this actinobacterium would be beneficial to develop robust and economically-feasible production

processes.

**Figure 1.** Synoptic scheme summarizing the signalling systems and the regulatory cascades associated with the physiological differentiation processes in *Microbispora* sp.

---

## Methods

An extensive investigation on proteomic changes associated with lantibiotic production was performed on the *Microbispora* sp. ATCC-PTA-5024 wild type strain at different growth stages by using combined two-dimensional difference in gel electrophoresis and mass spectrometry approaches. To evaluate the effect of NAI-107 on bacterial vitality, comparative proteomic experiments were also performed on a not producing strain following NAI-107 addition. The obtained results were then integrated with bioinformatics, fluorescence microscopy and molecular genetic experiments.

## Conclusions

The results of this study elucidate the regulatory networks, the biochemical pathways and the molecular processes occurring during growth and lantibiotic production (Figure 1), thus providing the first functional picture of a member of the *Microbispora* genus.

**OPTIMISATION OF THE BIOFLOCCULANT PRODUCED BY PANTOEAL SP., A NOVEL BACTERIUM ISOLATED FROM SEDIMENT FROM THE BEACH AT MTUNZINI, KWAZULU-NATAL, SOUTH AFRICA**

*A. Ugbenyen<sup>1</sup>, J. Simonis<sup>2</sup>, A. Basson<sup>1</sup>*

<sup>1</sup>*Department of Biochemistry and Microbiology, University of Zululand, Empangeni, South Africa*

<sup>2</sup>*Department of Hydrology, University of Zululand, Empangeni, South Africa*

**Background**

We screened microorganisms with potential for bioflocculation. An organism that secretes large amounts of bioflocculant was isolated from a sediment sample collected from the beach at Mtunzini on the coast of northern Kwazulu-Natal, South Africa

**Objectives**

The primary objective of this study was to optimised the bioflocculant production by the *Pantoea* sp. Further studies on the characterisation and applications of the bioflocculant produced by this organism will be done to underscore the biotechnological importance of this species as a producer of secondary metabolite useful for water and wastewater treatment

**Methods**

From detailed morphological and biochemical analysis, the isolate was identified as *Pantoea* sp. with 91% probability. Cultivation studies revealed that the isolate produced bioflocculant optimally with sucrose as a source of carbon (92.4% flocculating activity), inoculum size of 3% (v/v), at an initial pH of 6.0, with Ca<sup>2+</sup> as an aid to coagulation, and a production time of 96 h

**Conclusions**

We proposed that this organism has great potential as a producer of bioflocculant due to its ability of producing high flocculating activity when cultivation conditions are varied.

**Biotechnology and industrial microbiology**

**INFLUENCE OF THE MOLASSES AND AERATION ON THE PRODUCTION OF CELLULOSE BY GLUCONACETOBACTER XYLINUS**

R. Jaramillo-Lanchero<sup>1</sup>, O. Perna-Manrique<sup>1</sup>

<sup>1</sup>*Biología y Química, Universidad de Sucre, Sincelejo, Colombia*

**Background**

The bacterial cellulose (BC), produced by *Gluconacetobacter xylinus*, has been presented as a useful alternative to replace the vegetable cellulose as well as their use in many industrial applications. A carbon source and a system optimized for efficient aeration is important for a greater production of BC.

**Objectives**

This study has as its objective determine the effect of molasses in the production of BC by *Gluconacetobacter xylinus* IFO 13693 under static conditions and static with aeration.

**Methods**

The synthesis of bacterial cellulose (BC) by *Gluconacetobacter xylinus* was carried out in static culture discontinuous with and without aeration intermittent at room temperature, in the presence of molasses as the main carbon source at initial concentrations of 13.3 % (w/v). The concentration of BC concentrations, sucrose, glucose and fructose were determined each week. To determine the formation of cellulose and the coefficient of performance of the product was used the Microcal Origin software 6.0®.

**Conclusions**

By the fourth week, BC values found in the static and static and aeration experiments were around 103 g/L and for static 78.7 g/L, respectively. The kinetics for the hydrolysis of sucrose in the medium fixed the model of Michaelis-Menten, with a  $V_{max}$  of 0.0041 moles/L/h and 0.0036 moles/L/h, and a  $K_m$  of 0.021 M and 0.019 M for each culture condition, respectively. The yield coefficients have values of 0.013 to 8.7 g dry cellulose/g of glucose consumed. This shows the importance of the substrate and aeration on the synthesis of cellulose.

Moneke<sup>1</sup>, A. Moneke<sup>1</sup>*

*<sup>1</sup>Microbiology Department, University of Nigeria Nsukka, nsukka, Nigeria*

### **Background**

Laccases are polyphenol oxidases with numerous industrial and bioremediation application, most laccase activity is demonstrated in fungal species.

### **Objectives**

The study evaluated the potential of fungi isolated from selected agro waste for laccase production

### **Methods**

Fungi cultures were screened for laccase production by plate test using 2, 2, azinobis ( 3 ethyl benthiazoline 6 sulphonate) (ABTS) and submerged culture using synthetic medium.

### **Conclusions**

Utilisation of selected agro wastes (sawdust, plantain and banana peel) residue for laccase production was evaluated. Five out of twelve isolates were positive and identified as *GEOTRICUM* Spp, *CEPHALOSPORIUM* Spp, *TRICHODERMA* Spp, *TRAMETES* Spp and *FUSARIUM* Spp. Optimum enzyme activity was observed using *TRICHODERMA* Spp at 57.1U/ml followed by *TRAMETES* Spp with 51.99U/ml, *FUSARIUM* Spp had 29.2U/ml while *GEOTRICUM* Spp and *CEPHALOSPORIUM* Spp had 28.04U/ml and 9.72U/ml respectively. *TRICHODERMA* Spp was selected as the most potent in producing enzyme and therefore used for further studies. Effect of carbon source, inoculum sizes, pH and shaker speed was evaluated. Sawdust gave the highest yield with 151.17U/ml followed by plantain peel with 62.49U/ml, banana peel was least with 54.94U/ml. The optimum pH for sawdust, plantain peel and banana peel was 5.95, 5.94 and 5.83 respectively. using shaker incubator @ 150rpm with sawdust as carbon source, Laccase yield of 310U/ml was obtained at pH of 6 and temperature of 25 degree celcius inoculum size of 1000000 spores per ml. Thus sawdust can serve as cheap substrate for laccase production

**IDENTIFICATION OF CELLULOSOMAL ENZYMES FOR THE CONSTRUCTION OF CELLULOSOMES FROM CLOSTRIDIUM CELLULOVORANS**

C. Nagaya<sup>1</sup>, G. Ishikawa<sup>1</sup>, R. Tanaka<sup>1</sup>, T. Shibata<sup>1</sup>, K. Kuroda<sup>2</sup>, M. Ueda<sup>2</sup>, Y. Tamaru<sup>1</sup>, H. Miyake<sup>1</sup>

<sup>1</sup>Department of Life Sciences, Graduate School of Bioresources Mie University, Tsu, Japan

<sup>2</sup>Division of Applied Life Sciences, Graduate School of Agriculture Kyoto University, Kyoto, Japan

**Background**

*Clostridium cellulovorans* 743B, an anaerobic mesophile, produces a multienzyme complex, called the cellulosome, for the efficient degradation of cellulosic biomass. The cellulosome consists of carbohydrate enzymes and scaffolding proteins. The scaffolding protein CbpA consists of nine hydrophobic repeat domains (cohesin domains) for the binding of enzymes containing dockerin domains (cellulosomal enzymes).

**Objectives**

The expression pattern of the cellulosomal enzymes in the presence of various carbon sources was previously shown by proteome analysis, but the constituent enzymes of the cellulosome and their arrangement as a complex have yet to be determined. In this study, we identified the cellulosomal enzymes involved in the cohesin-dockerin interaction.

**Methods**

*C. cellulovorans* was cultivated on cellobiose and its cellulosome was purified from cell extracts using Avicel affinity chromatography. Fourteen enzymes were found to make up the cellulosome. Nine glutathione-S-transferase (GST) fusion mini-scaffolding proteins, each containing a cohesin domain of CbpA, were expressed in *Escherichia coli*. Cellulosomal enzymes that specifically or nonspecifically bound cohesin domains were detected by GST pull-down assay, which was also used to qualitatively analyze the interaction between five types of dockerin domains and all cohesin domains.

**Conclusions**

The interaction was found to be significantly dependent on the type of dockerin domain and the particular cohesin domain. These results imply a specific arrangement of enzymes in the cellulosome.

## **TOWARDS BIOTECHNOLOGICAL APPLICATION OF PSEUDOMONAS SPP. LIPASES**

M. Mandić<sup>1</sup>, J. Radivojević<sup>1</sup>, L. Djokić<sup>1</sup>, J. Nikodinović-Runic<sup>1</sup>, K. O'Connor<sup>2</sup>,  
B. Vasiljević<sup>1</sup>, S. Jeremić<sup>1</sup>

<sup>1</sup>Laboratory for microbial molecular genetics and ecology,  
Institute of Molecular Genetics and Genetic Engineering University of Belgrade,  
Belgrade, Serbia

<sup>2</sup>School of Biomolecular and Biomedical Science, University College Dublin, Dublin,  
Ireland

### **Background**

Microbial lipases catalyze hydrolysis of lipids, enabling bacteria to use vegetable and other oils as a carbon and energy source. Lipid hydrolysis share common intermediates with synthesis of valuable biopolymer polyhydroxyalkanoate (PHA). Bringing together these two processes in a single microorganism could further increase its potential for application in industrial biotechnology.

### **Objectives**

The objective was to screen *Pseudomonas* strains for lipase activity and capability to accumulate PHA in order to identify or to genetically modify these microorganisms to use waste cooking oils for production of valuable biopolymers.

### **Methods**

Seven *Pseudomonas* strains were tested for lipase activity on agar plates containing either Tween 80 or olive oil as carbon source. Bacterial capability to utilize reused fryer oil as a sole carbon source was tested in liquid medium. For selected *Pseudomonas* strains lipase activity was quantified using para-nitrophenyl palmitate enzyme assay and genetic determinants of lipase activity were amplified. In order to select appropriate host for the heterologous expression of lipase all *Pseudomonas* strains were tested for their ability to accumulate PHA.

### **Conclusions**

Among seven tested *Pseudomonas* strains *Pseudomonas aeruginosa* PAO1 showed highest lipase activity, while both *P. aeruginosa* PAO1 and *Pseudomonas putida* KT2440 could accumulate PHA. Since *P. aeruginosa* PAO1 is known opportunistic pathogen, *P. putida* KT2440 was more appropriate host for the biopolymer

production. *P. aeruginosa* PAO1 lipase-encoding genes were amplified and cloned into *P. putida* KT2440, and heterologous expression was optimized. Further analyses should reveal if these constructs have potential for the industrial application.

## **MYSTERI: MYCOBACTERIAL STEROIDS FOR INDUSTRY**

J. Loraine<sup>1</sup>, C. Barreiro<sup>2</sup>, M.C.M. Smith<sup>1</sup>

<sup>1</sup>Biology, University of York, York, United Kingdom

<sup>2</sup>Genetics, Institute of Biotechnology of León, León, Spain

### **Background**

Steroid based pharmaceuticals are extremely important for health, and conversion of cheap agricultural waste into highly valuable steroids is therefore an attractive prospect. Previous studies have indicated that in order to achieve this several areas need improvement, including the microbial strains used for bioconversion.

### **Objectives**

By utilizing the bacterium *Mycobacterium* sp. NRRL B-3805 we aim to replace the current microbial and chemical multistep processes with a single-step production of several steroids including androstenedione (**AD**), 11 $\alpha$ -hydroxy-androstenedione (**11 $\alpha$ -OH-AD**), dehydroepiandrosterone (**DHEA**) and **testosterone** from a cheap phytosterol feedstock.

### **Methods**

We have developed genetic engineering tools and procedures to manipulate *Mycobacterium* sp. NRRL B-3805 to improve the bioconversion of phytosterols. *Mycobacterium* sp. NRRL B-3805 metabolises steroids through the action of cholesterol oxidases, which modify the A-ring of the steroid core before cleaving the side chain through multiple enzymatic steps to produce **AD**. The genome of *Mycobacterium* sp. NRRL B-3805 was sequenced and was mined for potential cholesterol oxidases, hydroxysteroid dehydrogenases and other known enzymes involved in cholesterol catabolism. The genome mining enabled strain manipulation, as a means to optimise steroid production. Quantitation of steroid production was determined using GCMS.

### **Conclusions**

Production of **11 $\alpha$ -OH-AD** is being investigated by amplifying a putative 11 $\alpha$ -hydroxylase and the associated oxidoreductase from *Aspergillus ochraceus* cDNA and placing both coding sequences under bidirectional inducible promoters for expression in *Saccharomyces cerevisiae* and **11 $\alpha$ -OH-AD** production in media

containing **AD**. If active these enzymes will be expressed in *Mycobacterium* sp. NRRL B-3805.

## **BIOCALORIMETRY – AN EFFICIENT TOOL TO CONTROL MICROBIAL GROWTH AND PRODUCT FORMATION ON TOXIC FEEDSTOCKS**

M.T. Weichler<sup>1</sup>, S. Paufler<sup>1</sup>, T. Rohwerder<sup>1</sup>, H. Harms<sup>1</sup>, T. Maskow<sup>1</sup>

<sup>1</sup>*Environmental Microbiology, Helmholtz Centre for Environmental Research, Leipzig, Germany*

### **Background**

In the future, petrochemical industry may be replaced by biotechnological processes producing building block chemicals from renewable carbon and employing genetically engineered bacteria and other microorganisms. However, besides searching for suitable microbial production platforms, a major hurdle for a large-scale implementation of bioprocess-based technologies is the availability of economic and sustainable carbon sources.

### **Objectives**

An alternative substrate not competing with food or fodder production might be methanol due to its high synthesis capacities and a potentially sustainable production from natural gas, agricultural waste materials and biogas. However, main weaknesses of this C1 compound are its high volatility and toxicity. Its use in fermentation processes therefore calls for an innovative real-time control strategy.

### **Methods**

In this study, we decided on biocalorimetry as a basis for optimizing C1 substrate feed regimes in fermentations with the methylotrophic bacterium *Methylobacterium extorquens*. According to Hess' law every metabolic flux is quantitatively related to the heat production rate. Thus, calorimetry provides real-time stoichiometric and kinetic information of the fermentation process and allows reacting fast and efficiently to any metabolic changes.

### **Conclusions**

By comparing different calorimetry-based control strategies we established a procedure leading to the highest growth and product formation rates of *M. extorquens* on methanol. Additionally, we could show that this approach can be extended to other, even more toxic substrates such as formic acid. In conclusion, this study demonstrates that biocalorimetry is a very efficient tool for process control and can be applied to optimize any microbial product formation process.

**PHYSICOCHEMICAL AND BIOLOGICAL PROPERTIES OF THE ANTIFUNGAL  
POLYENE ANTIBIOTIC ROSEOFUNGIN**

A. Balgimbayeva<sup>1</sup>, A. Sadanov<sup>1</sup>, L. Trenozhnikova<sup>1</sup>, A. khasenova<sup>1</sup>, G. Ultanbekova<sup>1</sup>,  
B. Baimakhanova<sup>1</sup>

<sup>1</sup>Science Committee of the Ministry of Education and Science of the Republic of Kazakhstan, Institute of Microbiology and Virology, Almaty, Kazakhstan

**Background**

Due to the upward trend of fungal infections and development of resistance to existing drugs, the requirement for efficient antifungal agents has increased.

**Objectives**

Strain *Streptomyces roseoflavus* var. *roseofungini* 1-68, a producer of the antibiotic roseofungin.

**Methods**

Methods for spectrometry, NMR- and mass spectroscopy, elemental analysis, ozonolysis, and biological testing were used.

**Conclusions**

Roseofungin is an original natural highly efficient antifungal antibiotic. Roseofungin is amorphous powder, it decomposes at  $t > 130^{\circ}\text{C}$ ; fluoresces in UV, is quite soluble in pyridine, dimethylformamide, acetic acid, lower alcohols, soluble in water-saturated butanol and water acetone. UV-spectrum has 2 absorption maxima: at 263 nm and 363 nm. Roseofungin in concentrations of 0.5-12.5  $\mu\text{g/ml}$  inhibits the pathogenic agents of superficial and deep mycoses-trichophytosis, microsporia, candidiasis, cryptococcosis, sporotrichosis, chromomycosis, aspergillosis, and others. High virus-inhibiting activity of roseofungin has been established against various strains of influenza virus, Sendai paramyxovirus and Newcastle disease virus.

**DEVELOPMENT OF NEW BIOLOGICAL PREPARATIONS OF THE “RIZOVIT-AKS” SERIES BASED ON NODULE BACTERIA OF LEGUMINOUS PLANTS CULTIVATED IN KAZAKHSTAN**

A. Sadanov<sup>1</sup>, S. Aitkeldieva<sup>1</sup>, L. Trenozhnikova<sup>1</sup>, G. Ultanbekova<sup>1</sup>

<sup>1</sup>Committee of Sciences Ministry of Education and Sciences Republic of Kazakhstan, Institute of Microbiology and Virology, Almaty, Kazakhstan

**Background**

Development of biological preparations based on active strains of indigenous nodule bacteria of leguminous plants improves their productivity and soil capabilities.

**Objectives**

Strains of nodule bacteria isolated from the rhizosphere of leguminous plants: *Bradyrhizobium japonicum* M-1 from soybean, *Shinorhizobium meliloti* L5-1 from alfalfa, *Rhizobium leguminosarum* G2 from peas, *Mesorhizobium cicer* U-2O from chickpeas, *Rhizobium leguminosarum* B-1 from lentils.

**Methods**

Biotechnological and microbiological methods were used in the study.

**Conclusions**

Modification of the culture media containing bean broth or yeast extract has been carried out, and effect of carbon and inorganic salt sources on the growth and biomass accumulation of indigenous strains of nodule bacteria from soybean, alfalfa, peas, chickpeas, lentils studied. The best carbon source for most strains of root nodule bacteria is sucrose at a concentration of 4-10.0 g/L. A number of salts (CaCO<sub>3</sub>, MnSO<sub>4</sub>, ZnSO<sub>4</sub>, CoCl<sub>2</sub>) stimulated the biomass accumulation of nodule bacteria strains up to 10<sup>11</sup> CFU/ml.

Application of biological preparations of the “Rizovit-AKS” series to inoculate the seeds of leguminous crops reduces the time required for passing phenophases by legumes: on average 2 to 3 days for soybean; 2 to 5 days for peas; up to 2 days for lentils, 2 to 4 days for alfalfa. Biopreparations increase the plant growth, green mass and number of nodules under all tested soil and climatic conditions of Kazakhstan. With the use of biopreparations, an increase in the yields of leguminous crops: for soybeans by 3.2 t/ha (34.4%), lentils – by 3.3 t/ha (41.3%); peas – by 8.3 t/ha (140.7%).

**FROM ORGANIC WASTE TO RENEWABLE ENERGY: A NOVEL HYBRID DARK FERMENTATION-PHOTOHETEROTROPHIC BIOHYDROGEN PRODUCTION APPROACH**

I.Z. Boboescu<sup>1</sup>, V.D. Gherman<sup>2</sup>, G. Lakatos<sup>1</sup>, B. Pap<sup>1</sup>, M. Ilie<sup>2</sup>, E. Kondorosi<sup>1</sup>, G. Maróti<sup>1</sup>

<sup>1</sup>Biochemistry, Biological Research Centre Szeged, Szeged, Hungary

<sup>2</sup>Hydrotechnics, Politehnica University Timisoara, Timisoara, Romania

**Background**

Our current society is confronted with a series of global geopolitical, economic, energetic and climate crises. While there is no common solution for all these issues, there is an obvious main connection, the need for a novel renewable and environmentally friendly energy carrier. Hydrogen gas is considered an attractive alternative to fossil fuels with certain methods of biohydrogen production being able to utilize various low-priced industrial and agricultural wastes, thus coupling organic waste treatment with renewable energy generation.

**Objectives**

By designing a novel hybrid dark fermentation-photoheterotrophic degradation biohydrogen production process using industrial wastewater as a substrate we aim to resolve the major scientific and technical bottle-necks preventing the biohydrogen production systems to become economically feasible, bringing thus the technology closer to the industry.

**Methods**

A laboratory-scale bioreactor experimental setup was developed in order to identify the most suited microbial and micro-algal consortia, as well as the key metabolic pathways involved. In addition, an advance statistical design of experiments approach was used to identify the influence and interactions of key micro-environmental factors.

**Conclusions**

The obtained preliminary results prove that this novel system has the potential to produce considerably more H<sub>2</sub> yields compared to traditional systems as well as generate valuable oils through the micro-algal metabolic activity. In addition, such a novel technology could capture the generated CO<sub>2</sub> produced during the dark fermentation step, and used it by the micro-algal species together with the dark fermentation effluent.

**EXTRACELLULAR N-ACETYLGLUCOSAMINE INCREASES HYALURONAN YIELD AND ITS MOLECULAR WEIGHT IN CULTURE OF STREPTOCOCCUS ZOOEPIDEMICUS**

L. Franke<sup>1</sup>, A. Růžicková<sup>1</sup>, M. Krčmář<sup>1</sup>, D. Smirnou<sup>1</sup>, S. Pepeliaev<sup>1</sup>, V. Velebný<sup>1</sup>

<sup>1</sup>Biotechnology Department, Contipro Biotech s.r.o., Dolní Dobrouč, Czech Republic

**Background**

Hyaluronan (hyaluronic acid, HA) is a linear polysaccharide composed of alternating D-glucuronic acid (GlcUA) and N-acetylglucosamine (GlcNAc) linked by  $\beta(1,4)$  and  $\beta(1,3)$  glycosidic bonds. This macromolecule is found in various tissues of vertebrates, where it has different biological functions. Industrially, HA has been manufactured by fermentation of group C streptococci.

This polysaccharide is produced by processive synthase from the activated UDP-sugars (UDP-GlcA and UDP-GlcNAc). A positive correlation between molecular weight (MW) and concentration of UDP-GlcNAc was previously reported [1].

**Objectives**

To increase hyaluronan yield or its molecular weight by strengthening UDP-precursors biosynthesis.

**Methods**

Fermentations were carried out in fermentor Sixfors (Infors HT, Switzerland) with working volume of 300 ml. HA yield was determined by isopropanol precipitation. HA Mw was analysed by SEC-MALLS.

**Conclusions**

In order to increase yield or molecular weight of hyaluronic acid in *Streptococcus zooepidemicus* fermentation, cultivation medium was supplemented with GlcUA and GlcNAc. These molecules are involved in hyaluronan biosynthetic pathway.

Extracellular GlcNAc significantly increased both HA yield and molecular weight (35% and 21% respectively). HA yield positively correlated with GlcNAc concentration up to 1g/l. Higher concentrations had detrimental effect on HA production. No significant

effect on HA yield was observed for GlcUA addition.

**Biotechnology and industrial microbiology**

## **EVALUATION OF BACTERIAL ENZYMES IN DEGRADATION OF TEXTILE DYES**

S. Ertuğrul Karatay<sup>1</sup>, N. Koçberber Kılıç<sup>1</sup>, G. Dönmez<sup>1</sup>

<sup>1</sup>Biology, ANKARA UNIVERSITY, Ankara, Turkey

### **Background**

Because of the ease of their synthesis and the greatest variety of colors, azo dyes are the largest class of synthetic dyes. Generally they are very recalcitrant to biodegradation. Thus, in the current study the biodegradation of an azo dye namely Remazol Blue (RB) by wastewater- isolated bacteria (*Bacillus megaterium*, *Micrococcus luteus* and *Bacillus pumilus*) has been investigated in media containing molasses as a carbon and energy source.

### **Objectives**

The goal of this work was to identify decolorization and degradation properties of Remazol Blue dye by bacterial strains at batch scale .

### **Methods**

Enzyme activity: The reaction mixture contained 400 µl of 50 mM sodium phosphate buffer (pH 7.0), 200 µl of the sample and 200 µl of Remazol Blue. The reaction was initiated by the addition of 200 µl NADH (final concentration 2 mM) and followed photometrically.

Bioremoval assays: Experiments were carried out at different (from 28.7 to 97.9 mg/L) dye concentrations at pH 7 throughout 3 days.

### **Conclusions**

*Bacillus* -derived azoreductases were responsible for biodegradation of RB. The maximum azoreductase activity was obtained as 39.9 U/ml for *B. pumilus* at 2<sup>nd</sup> day. The removal yields of *B. pumilus* were 71.0%, 74.3%, 67.2% and 69.9% for 28.7, 57.9, 78.3 and 97.9 mg/L dye, respectively. There were also high azoreductase activities for *B. megaterium* at the first and second days of incubation time such as 37.4 and 33.6 U/ml while *M. luteus* did not show any azoreductase activity.

**REMOVAL OF NI(II), CU(II) AND CR(VI) AND EPS PRODUCTION BY BACTERIAL CULTURES ISOLATED FROM ANKARA STREAM**

*N. KOÇBERBER KILIC<sup>1</sup>, G. KÜRKÇÜ<sup>1</sup>, D. KUMRUOĞLU<sup>1</sup>, G. DÖNMEZ<sup>1</sup>*

*<sup>1</sup>BIOLOGY, ANKARA UNIVERSITY, ANKARA, Turkey*

**Background**

Among many heavy metals, Cr(VI), Ni(II) and Cu(II) are the ones having many usage fields, and therefore wastewaters including them have to be treated.

**Objectives**

This study aimed to isolate Ni(II), Cu(II), Cr(VI) resistant-bacteria from Ankara Stream (Turkey) and determining EPS production and bioremoval capacities of them under different conditions.

**Methods**

Experiments were done with bacterial cultures in different media (active sludge: AS; active sludge with molasses: MAS) including Ni(II), Cu(II), Cr(VI) at varied pH values (6-9). Heavy metals were determined spectrophotometrically at 340 nm for Ni(II); 460 nm for Cu(II); 540 nm for Cr(VI). EPS amount was also investigated.

**Conclusions**

Mixed bacterial cultures had higher bioremoval than the pure cultures. Six heavy metal-resistant strains were purified. Strain 5 had the highest Cu(II) (69.1%) and Cr(VI) (43.1%) removal under 25 mg/l heavy metal at pH 7. The same strain was the efficient bacterium in bioremoval and EPS production. It had EPS amount as 1.05 g/l at 25 mg/l Cr(VI), and 0.74 g/l at similar Cu(II) concentration. Especially mixed and also pure bacteria could be used as a biosorbent in treatment of heavy metals.

**BIOETHANOL PRODUCTION FROM AGRICULTURAL WASTES BY  
SACCHAROMYCES CEREVISIAE**

*M. Erdoğan<sup>1</sup>, S. Ertuğrul Karatay<sup>1</sup>, S. Dönmez<sup>2</sup>, G. Dönmez<sup>1</sup>*

<sup>1</sup>*Biology, Ankara University, Ankara, Turkey*

<sup>2</sup>*Food Engineering, Ankara University, Ankara, Turkey*

**Background**

The depletion of fossil fuels and the concerns about environment have led scientists to find alternative renewable energy sources. Bioethanol is the most widely used liquid biofuel at present among these alternative fuels. Feedstock costs are the major part of the process. Thus, considerable work has been performed toward production of bioethanol using various kinds of feedstocks such as starch rich agricultural wastes and cellulosic biomass.

**Objectives**

To demonstrate the utilization capacity of agricultural wastes (apple and carrot pomaces) as feedstocks for bioethanol production.

**Methods**

*Feedstock preparation:* Appropriate amounts of apple and carrot pomaces were mixed with distilled water and homogenized to obtain desired concentration of feedstock solutions. Different pretreatment methods were performed to find the most effective way to obtain fermentable sugars in pomaces.

*Fermentation conditions:* The yeast cells were precultured in YPG medium at pH 6. 10% yeast suspension was aseptically transferred to anaerobic fermentation medium which is prepared by pomace sugar containing distilled water.

*Biomass, sugar and ethanol determination:* Yeast biomass was determined by measuring optical density. The sugars were determined by phenol-sulphuric acid method. The bioethanol concentration was analyzed using gas chromatography.

**Conclusions**

Higher ethanol production values were obtained from apple pomace rather than carrot. The pretreatments performing with acid were more effective than the ones

performed with base. The highest ethanol production was obtained when the apple pomace was pretreated with 0.25% (v/v)  $\text{H}_2\text{SO}_4$ .

## **BORON REMOVAL FROM AQUEOUS SOLUTIONS USING RHODOTORULA MUCILAGINOSA AS A BIOSORBENT**

*D.N. ÇAKIR<sup>1</sup>, B. ERTİT TAŞTAN<sup>2</sup>, N. KOÇBERBER KILIÇ<sup>1</sup>, G. DÖNMEZ<sup>1</sup>*

*<sup>1</sup>BIOLOGY, ANKARA UNIVERSITY, Ankara, Turkey*

*<sup>2</sup>Life Sciences Application and Research Center and Health Services Vocational School, GAZİ UNIVERSITY, Ankara, Turkey*

### **Background**

Boron (B) is a naturally occurring element found in earth's crust, rocks, soil, and water. Although B is an essential element and used at many industries, it could be toxic for organisms in excess concentrations.

### **Objectives**

In the present study we aimed to remove B from aqueous media via biosorption by *Rhodotorula mucilaginosa*, which was isolated from B-contaminated wastewater.

### **Methods**

Batch culture experiments including pH (4-7), increasing B (15-20 mg/L), biomass concentrations (1-4 g/L) and different biosorption methods (wet, dried and formaldehyde-treated cells) were carried out at 25±2 °C, at 100 rpm for 120 min. Boron concentrations were determined spectrophotometrically by measuring the absorbance at 585 nm with using carmine.

### **Conclusions**

According to the data obtained, the optimum pH was found as 6 for the maximum B removal. Under 15.35 mg/L B, the highest biosorption was determined as 23.78%. Biosorption was increased with increasing biomass and the maximum yield (31.92%) was found at 4 g/L biomass. Wet cells removed B more effectively than formaldehyde-treated or dried cells and the yields were 23.78%, 19.31% and 12.07%, respectively. It can be concluded that *R. mucilaginosa* might be an effective biosorbent in B removal processes.

<sup>2</sup>*Department of Biology, Philipps-University Marburg, Marburg, Germany*

#### Background

Itaconic acid is a promising bio-based platform chemical for the production of pharmaceuticals, adhesives and polymers. *Ustilago* is a promising fungal host for the production of itaconic acid. Contrary to established filamentous itaconate producers, *Ustilago* grows unicellularly. This has distinct process advantages relating to morphology control, viscosity and aeration. However, the itaconate production yield, titer and rate of *Ustilago* are below that of the commercial production hosts. In order to optimize itaconate production in *Ustilago*, detailed biochemical knowledge is needed.

#### Objectives

To characterize the itaconate production pathway in *Ustilago* in order to enable metabolic engineering.

#### Methods

An itaconate gene cluster was identified in *Ustilago*. The function of the cluster genes and their encoded proteins was characterized by knockout and overexpression. The activity of two essential catalytic proteins was determined *in vivo* by permeabilized cell assays and *in vitro* by *E. coli* expression and purification.

#### Conclusions

The genes *tad1* (*trans*-aconitate decarboxylase), *itp1* (Major Facilitator Superfamily extracellular itaconate transporter), *adi1* (aconitate- $\Delta$ -isomerase), *mtt1* (mitochondrial tricarboxylate transporter), and *ria1* (transcriptional itaconate regulator) are involved in the itaconate biosynthesis and possibly its further conversion.

In contrast to the known itaconate biosynthesis pathway of *Aspergillus terreus*, *Ustilago*'s itaconate production proceeds first via an isomerization from *cis*- to *trans*-aconitate, followed by decarboxylation of the *trans*-aconitate. First metabolic engineering attempts were successful, enhancing *U. maydis*' itaconate production twofold by overexpression of *ria1* or *mtt1*. This work lays the foundation for further

optimization of *U. maydis*' itaconate biosynthesis and is therefore a further step towards industrial application of this promising biocatalyst.

**PURIFICATION AND CHARACTERIZATION OF A LIPASE WITH HIGH SYNTHETIC ACTIVITY FROM RHIZOPUS STOLONIFER**

M. Takó<sup>1</sup>, A. Kotogán<sup>1</sup>, A. Sója<sup>1</sup>, A. Kecskeméti<sup>1</sup>, K.C. Monda<sup>2</sup>, T. Papp<sup>1</sup>,  
C. Vágvolgyi<sup>1</sup>

<sup>1</sup>Department of Microbiology, University of Szeged, Szeged, Hungary

<sup>2</sup>Department of Microbiology, Vidyasagar University, Midnapore - West Bengal, India

**Background**

Filamentous fungi are extensively studied due to their exoenzyme producing ability. Since lipases are effectively utilizable in various industrial processes, special attention is paid for these enzymes. Development of environmentally friendly technologies requires lipases able to catalyze the rapid synthesis and translocation of esters. Isolation and analysis of such enzymes contributes to the knowledge of these catalytic processes, and provides data on new lipases with potential biotechnological interest.

**Objectives**

A *Rhizopus stolonifer* isolate has been identified as high-yield lipase producer in our previous tests. Further studies revealed that the crude enzyme has significant transesterification activity. Therefore, our present work has focused on the purification and characterization of this *R. stolonifer* lipase.

**Methods**

Isolate was grown on liquid medium containing wheat bran. To purify the enzyme, after filtration and centrifugation, ammonium sulphate precipitation, size-exclusion and ion-exchange separations were performed. Biochemical characterization assays including substrate specificity, temperature and pH tolerance studies, and examination of the effect of some ions and organic solvents on the activity were carried out.

**Conclusions**

The optimal temperature and pH for the activity were about 50 °C and pH 5.0, respectively. The lipase has broad substrate specificity because it has effectively hydrolyzed the substrates containing fatty acids from C6 to C16. Enzyme activity was stimulated by 5% ethanol, butanol and propanol. Results showed that certain alkanes could stabilize the active conformation of the enzyme. The isolated *R. stolonifer* lipase exhibited high esterification and transesterification activity at 40-50 °C. This research was supported by the Hungarian Research Fund (OTKA PD 112234).

**INVESTIGATION OF THE TRANSESTERIFICATION AND ESTERIFICATION  
PROPERTIES OF EXTRACELLULAR LIPASE ENZYMES FROM  
MUCOROMYCOTINA FUNGI**

A. Kotogan<sup>1</sup>, A. Kecskeméti<sup>1</sup>, T. Papp<sup>1</sup>, A. Szekeres<sup>1</sup>, C. Vágvölgyi<sup>1</sup>, M. Takó<sup>1</sup>

<sup>1</sup>Department of Microbiology, University of Szeged, Szeged, Hungary

**Background**

Recent years, there is a fast-growing interest on the catalytical activities display by lipase enzymes, especially focusing on their synthetic activity in organic solvents. Translocation and synthesis of ester linkages result various aroma-, phenyl- and alkyl esters and different polymers. Many of these compounds have important role in the food-, pharmaceutical-, and oleochemical industries as well as in the biodiesel production. In these industries, development of modern environmentally friendly biotechnological technologies requires the exploration and utilisation of new microbial enzymes.

**Objectives**

Lipases can be produced by certain *Mucoromycotina* fungi as well, but only some of these enzymes have been tested for their synthetic activity in organic media. In this work, we evaluated the esterification and transesterification capacities of *Rhizomucor*, *Rhizopus*, *Mucor* and *Mortierella* lipase enzymes through alkyl ester synthesis, and we characterise of their fatty acid preference during these reactions.

**Methods**

Reactions were carried out in non-aqueous condition using lyophilised crude enzyme preparations. Transesterification was studied between *p*-nitrophenyl-palmitate and ethanol, while esterification reactions were examined with different chain length fatty acids and methanol. The effect of the reaction time on the ester production was also evaluated. Synthetic esters produced were detected by a GC-FID technique.

**Conclusions**

Each lipase catalysed the transesterification significantly faster than esterification. High ethyl-palmitate production was reached by lipases from *Rhizopus stolonifer* and *Mucor corticolus* strains. During esterification reactions, the tested enzymes showed increased alkyl ester synthesis in the presence of medium-chain fatty acids. This

research was supported by the TÁMOP-4.1.1.C-12/1/KONV-2012-0012 and the Hungarian Research Fund (OTKA PD 112234).

#### **NOVEL SMALL-SCALE AND ENZYMATIC TEST SYSTEMS TO ANALYSE FULL OPERATING BIOGAS PLANTS**

S. Refai<sup>1</sup>, U. Deppenmeier<sup>1</sup>

<sup>1</sup>*Applied Microbiology, Institute for Microbiology and Biotechnology, Bonn, Germany*

#### **Background**

One important renewable energy source is biomass from energy crops and organic waste that is used for the production of biogas. Biogas mainly consists of CH<sub>4</sub> and CO<sub>2</sub> and is generated by anaerobic fermentation of organic matter.

#### **Objectives**

For a more precise and targeted optimization it is crucial to understand the biological processes during biogas production.

#### **Methods**

Using authentic samples from full operating biogas plants it was possible to develop batch and continuous reactors mirroring the conditions and the performance of the full-scale biogas plant. With these test systems it was possible to observe effects of different substrates for syntrophic bacteria and for methanogenic archaea on biogas formation.

Furthermore, the development of novel sensors in biogas plants to quantify the activities of key enzymes is desirable. A potential candidate is the heterodisulfide reductase (Hdr). Methanogenesis finally results in the formation of the heterodisulfide, which is regenerated by the Hdr. In acetoclastic methanogens the Hdr is tightly bound to the cytoplasmic membrane but in hydrogenotrophic methanogens it is located in cytoplasm.

#### **Conclusions**

Most biogas sludge samples were stimulated by the addition of ethanol or acetate, which leads to increasing methane production by 35-126 %. These results indicate that syntrophic ethanol oxidation and acetoclastic methanogenesis were not rate limiting in routinely operating biogas plants.

Our test system allows a quantification of hydrogenotrophic/aceticlastic methanogens in biogas sludge based on Hdr activity. In summary 26% of total Hdr activity was found in the membranes while the cytoplasmic fraction contained 74% of total activity.

**EXPRESSION OF AGARICUS BISPORUS MANGANESE PEROXIDASES IN SCHIZOPHYLLUM COMMUNE**

A.M. Vos<sup>1</sup>, T. van den Brule<sup>1</sup>, K.G.J. Nierop<sup>2</sup>, L.G. Lugones<sup>1</sup>, H.A.B. Wösten<sup>1</sup>

<sup>1</sup>Biology, Microbiology, Utrecht, Netherlands

<sup>2</sup>Earth sciences, Organic geochemistry, Utrecht, Netherlands

**Background**

White rot fungi are thought to degrade lignin using AA2 enzymes like lignin peroxidase, manganese peroxidase (MnP) and versatile peroxidase. It is unclear if *S. commune* is a white rot or brown rot fungus. This basidiomycete is a poor lignin degrader. No genes encoding AA2 enzymes are found in its genome, while it is enriched in AA9 genes. This would place *S. commune* in between brown and white rot fungi. We here introduced two *A. bisporus mnp* genes in *S. commune*.

**Objectives**

Introduction of *A. bisporus* MnPs in *S. commune* and its effect on the lignin degrading capacity of *S. commune*.

**Methods**

qPCR verified expression of these genes in *S. commune*. Decoloration of RBBR by *mnp* expressing *S. commune* strains indicated production of active MnP. This was confirmed using the MBTH/DMAH assay. Addition of hemin to standing cultures increased MnP activity 5-fold. Pyrolysis analysis indicated that a *S. commune* strain expressing both MnPs of *A. bisporus* degraded lignin in birchwood .

**Conclusions**

*A. bisporus* MnPs were successfully introduced and expressed in *S. commune*. The G subunit of lignin seems to be preferentially degraded by *S. commune* MnP expressors. The ligninolytic pathway of litter degrading fungi can be reconstituted in *S. commune*.

Institute of Molecular Genetics and Genetic Engineering University of Belgrade,  
Belgrade, Serbia

<sup>2</sup>Department of Life Sciences,  
Institute for Multidisciplinary Research University of Belgrade, Belgrade, Serbia

<sup>3</sup>Department of Biochemistry, Faculty of Chemistry University of Belgrade, Belgrade,  
Serbia

**Background**

Enzyme 4-oxalocrotonate tautomerase (4-OT) encoded by *xylH* gene is a part of aromatic compounds degradation pathway in *Pseudomonas putida* mt-2. Due to its promiscuous activity, 4-OT was described to catalyse Michael-type addition of acetaldehyde to  $\beta$ -nitrostyrene, the isomerisation of *cis*-nitrostyrene to *trans*-nitrostyrene as well as aldol condensation and dehydration as free enzyme. Whole cell system based on recombinantly expressed 4-OT has been developed and shown to be effective biocatalyst of asymmetric Michael addition of acetaldehyde to  $\beta$ -nitrostyrene.

**Objectives**

The objective of this study was to improve biocatalytic production of 4-nitro-3-phenylbutanal employing two strategies: biocatalyst immobilization and product recovery using Amberlite XAD-2 polymeric adsorbent.

**Methods**

Whole cell biocatalyst was immobilized in 4% alginate gel. Capsules of 1 and 2 mm in diameter were made. Liquefaction of the capsules core was performed by addition of sodium citrate. Depletion of  $\beta$ -nitrostyrene was monitored by reduction of absorbance at 320 nm. Product was recovered from aqueous reaction buffer by addition of XAD-2 beads, followed by elution in minimal volume of ethylacetate.

**Conclusions**

Biocatalytic production of 4-nitro-3-phenylbutanal was improved by whole-cell immobilization in alginate capsules. Capsules were used in 12 reaction cycles, and retained 20% of the activity after two months of storage. Bioprocess was further improved by using XAD-2 beads for improved product recovery. With this

modification, the amount of organic solvent was reduced 20-fold in comparison to previously reported method making this process more environmentally friendly.

**COMPARATIVE GENOMIC ANALYSIS OF SOLVENT PRODUCING  
CLOSTRIDIUM ACETOBUTYLICUM AND CLOSTRIDIUM BEIJERINCKII STRAINS**

C. Mendez-Garcia<sup>1</sup>, B. Jia<sup>1</sup>, Z. Ye<sup>1</sup>, W. Lin<sup>1</sup>, I.K. Cann<sup>1</sup>, R.I. Mackie<sup>1</sup>

<sup>1</sup>Energy Biosciences Intitute, Institute for Genomic Biology, Urbana, USA

**Background**

The clostridial acetone-butanol-ethanol (ABE) fermentation pathway is complex and represents one of the oldest industrial fermentations. Interest in the production of solvents from lignocellulosic sources has increased in recent years. However, low production yields, end-product inhibition and phage infections remain as disadvantages in the ABE fermentation.

**Objectives**

Genetic and metabolic engineering strategies leading to a stable, high-yielding process require prior genomic exploration of diverse solventogenic Clostridial strains.

**Methods**

Ten strains of *C. acetobutylicum* and *C. beijerinckii* were selected from batch fermentation experiments according to their solvent yields. Genomes and plasmids (when present) were sequenced using the Illumina HiSeq platform. Complete genomes were obtained through *de novo* and reference-guided assembly comparison with coverages of ~ 100x. Annotation was performed using RAST (<http://rast.nmpdr.org>). Key enzymes for solvent production were mapped in the genomes and/or plasmids to allow variant detection and comparison in future RNA-seq experiments. Raw Illumina reads were used as input for CRISPR structure detection using the Crass software (<http://ctskennerton.github.io/crass/>). Putative CRISPR fragments were assembled and queried against the CRISPR database (<http://crispr.u-psud.fr/crispr/>). Complete CRISPR structures were detected in 7 out of 10 genomes (average 2.5 CRISPR structures per strain), and repeat/spacer units were detected in all 10 sequenced strains. An alignment-based approach revealed the existence of uneven distribution of types (11 detected) across their genomes.

**Conclusions**

In combination, our results provide a sound basis for directed generation of engineered Clostridial solventogenic strains, with the potential to re-launch the ABE fermentation as a competitive industrial fermentation.

## **REROUTING OF CARBON FLUX TOWARDS GLYCEROL PRODUCTION IN YEAST *SACCHAROMYCES CEREVISIAE***

M. Semkiv<sup>1</sup>, K. Dmytruk<sup>1</sup>, C. Abbas<sup>2</sup>, A. Sibirny<sup>1</sup>

<sup>1</sup>Department of Molecular Genetics and Biotechnology,  
Institute of Cell Biology NAS of Ukraine, Lviv, Ukraine

<sup>2</sup>Archer Daniels Midland Co, Research Center, Decatur IL, USA

### **Background**

Currently there is an interest in development of microbial strains effectively converting cheap feedstocks to glycerol. Facultative anaerobic yeast *Saccharomyces cerevisiae* can be a good platform for development of recombinant strains overproducing glycerol under low-aeration conditions. In *S. cerevisiae* glycerol is synthesized from dihydroxyacetone phosphate by the action of glycerol-3-phosphate dehydrogenase (Gpd1) and glycerol-3-phosphate phosphatase (Gpp2). Other road of dihydroxyacetone phosphate catabolism occurs by its isomerization to glyceraldehyde-3-phosphate with triose phosphate isomerase (Tpi1), resulting to ethanol formation.

### **Objectives**

We aimed to construct recombinant strains with reduced Tpi1 activity and increased Gpd1 and Gpp2 activities.

### **Methods**

Homologous recombination was used for partial substitution of *TPI1* gene promoter region with selective marker. Obtained strains contain 100, 50 or 25 base pairs of native *TPI1* gene promoter before *TPI1* ORF, and revealed corresponding sequential decreases in Tpi1 activity. Multicopy integration module was used for expression of hybrid *GPD1-GPP2* ORF (encoding artificial fusion of both enzymes) under the control of strong constitutive promoter of the alcohol dehydrogenase gene.

### **Conclusions**

Recombinant *S. cerevisiae* strains with 50 or 25 bp version of *TPI1* promoter revealed up to 2 times increase in glycerol production as compared to the WT strain. Recombinant strains expressing *GPD1-GPP2* fusion produced approximately 4 times more glycerol than that of WT strain. Combination of both approaches resulted to 5-fold increase of glycerol production as compared to the WT strain.

**METHANOTROPHIC EXTREMOPHILES: FROM UNUSUAL PHYSIOLOGY TO NEXT GENERATION BIOCATALYSIS**

M. Kalyuzhnaya<sup>1</sup>, S. But<sup>2</sup>

<sup>1</sup>Biology, San Diego State University, San Diego, USA

<sup>2</sup>SIO, UCSD, San Diego, USA

**Background**

The long-term goal of this research is to develop a robust microbial platform for conversion of greenhouse gases (CH<sub>4</sub> and CO<sub>2</sub>) into valuable chemicals as an alternate approach to widespread (bio)gas-flaring.

**Objectives**

The main objective of this project is to generate a comprehensive vision of methane oxidation in a model methanotroph (*Methylobacterium alcaliphilum* 20Z) using modern systems biology approaches.

**Methods**

A multi-tiered systems-level approaches (genomics/mutagenesis, transcriptomics, metabolomics and fluxomics) were used to validate the metabolic network in *M. alcaliphilum* 20Z grown on methane and methanol during both, steady state and transitions from restricted to active utilization of C1-substrate.

**Conclusions**

Comparisons of different growth conditions highlighted functions important for methane oxidation and for the re-activation of methane oxidation machinery. Complete genome sequences of the methanotrophic strain enabled genome-wide metabolic reconstruction. The first stoichiometric flux balance model of methane utilization was constructed and validated. A new vision of the core methanotrophic functions will be presented. The majority of the data (methane oxidation parameters, growth yield, mutant phenotypes) suggest that *direct coupling* between methanol and methane oxidation is the most compelling mode of methane activation. The reconstruction of spatial organization of the metabolic network coupled with the computational modeling enables a mechanistic understanding and systematic analysis of the interplay between core methane oxidation processes and overall performance of the biological system. New data were used to improve conversion of the C1-substrate into value-added chemicals and fuels.

**OPTIMIZATION OF LEVAN PRODUCTION BY BACILLUS LICHENIFORMIS  
ANALYSED BY THE RESPONSE SURFACE METHOD**

B. Kekez<sup>1</sup>, M. Ljesevic<sup>1</sup>, G. Gojgic-Cvijovic<sup>2</sup>, D. Jakovljevic<sup>2</sup>, V. Beskoski<sup>1</sup>,  
M.M. Vrvic<sup>1</sup>

<sup>1</sup>Department of biochemistry, Faculty of Chemistry University of Belgrade, Belgrade, Serbia

<sup>2</sup>Center for Chemistry, Institute of Chemistry Technology and Metallurgy, Belgrade, Serbia

**Background**

Levan is a fructose based exopolysaccharide produced by microorganisms as an energy reserve and defense. It has present low viscosity, high solubility in water, biocompatibility and other properties that have industrial and medicine applications. Levan-type polymers have been reported as hypocholesterolemic, cell-proliferating, anti-inflammatory and antitumour agent, an immune modulator, thickener, stabilizer, flavors, and a aroma carrier [1].

Response surface methodology (RSM) is the most popular optimization method used in recent years because the application of statistical designs for experiments and its modeling defines the effect of various factors and its interaction [2].

**Objectives**

The aim of this study was to optimize fermentation medium composition for levan production by *Bacillus licheniformis* strain.

**Methods**

Basic medium for levan production contains sucrose as carbon source, yeast and beef extract as nitrogen source, and its pH level is important for excretion of polysaccharide. In this work it has been shown that high levan production by the studied strain could be achieved with ammonium chloride as a sole nitrogen source. Influence of three independent variables (pH, sucrose and ammonium-chloride concentration) was investigated using Box-Behnken statistic design.

**Conclusions**

Based on response surface model that we obtained, in medium that contain 200 g/L sucrose, 1.44 g/L ammonium-chloride and pH 7.5 maximum concentration of levan (41.29 g/L) is reached, which was in agreement with experimental data.

**MOLECULAR BREEDING OF YEAST CO-DISPLAYING ENDO- AND EXO-TYPE ALGINATE LYASES TO COMPLETELY UTILIZE MACROALGAE**

T. Takagi<sup>1,2</sup>, T. Shibata<sup>2,3,4</sup>, H. Morisaka<sup>1,2</sup>, K. Kuroda<sup>1,2</sup>, M. Ueda<sup>1,2</sup>

<sup>1</sup>Div. Appl. Life Sci., Grad. Sch. Agric. Kyoto Univ., Kyoto, Japan

<sup>2</sup>CREST-JST, Japan

<sup>3</sup>Dept. Life Sci., Grad. Sch. Bioresour. Mie Univ., Mie, Japan

<sup>4</sup>Ind. Technol. Innov. Inst., Mie Univ., Mie, Japan

**Background**

Brown macroalgae is characterized by a large size and high productivity without requiring arable land, irrigation water, or fertilizer. It is a raw material suitable for productivity of bioenergy and biochemical productions. However, alginate, which is the main component of brown macroalgae, is an undegradable polysaccharide with poly (M)-, poly (G)-, and poly (MG)-blocks composed of  $\alpha$ -l-guluronic acid (G) and its C5 epimer,  $\beta$ -d-mannuronic acid (M), as monomeric units.

**Objectives**

In order to degrade alginate polymers effectively, both endo- and exo-type alginate lyases are necessary. Therefore, we co-displayed endo- and exo-type alginate lyases from the alginate-degrading marine bacterium *Saccharophagus degradans* [1] on the cell surface of *Saccharomyces cerevisiae* with our original method, cell surface engineering technology [2].

**Methods**

The alginate lyases from *S. degradans* were produced as fusion proteins with cell wall anchoring domain of  $\alpha$ -agglutinin in *S. cerevisiae*. The production and localization of alginate lyases on the yeast cell surface were confirmed by immunofluorescence microscopy. The enzyme activities of the displayed alginate lyases were measured by using the dinitrosalicylic acid method.

**Conclusions**

The results suggested that the engineered yeasts co-displaying endo- and exo-type alginate lyases could lead to efficient production of monomeric units from alginate polymers [3]. This system is a unique easily feasible to utilize any biomass.

<sup>2</sup>División de Estudios de Posgrado Facultad de Ciencias Médicas y Biológicas “Dr. Ignacio Chávez”, Universidad Michoacana de San Nicolás de Hidalgo Mexico, Morelia, Mexico

**Background**

Contrary to temperate regions, knowledge on laccase producing fungal species from ecosystems allocated at neotropical regions is still scarce. Search for ligninolytic fungi in these ecosystems can provide laccases with novel biotechnological potential.

**Objectives**

The goal of this study was to explore novel fungal species with laccase activity from different forest ecosystems.

**Methods**

Fungal species were isolated from soil and basidiocarp samples collected from five different geographic regions with dominant vegetation of *Pinus* spp., *Abies* spp., and *Quercus* spp. Extracellular laccase activity by fungal isolates were analyzed by guaiacol assay. Identification of laccase positive fungi was carried out by sequence comparison and phylogenetic analysis of internal transcribed region (ITS1F-5.8S-ITS4B) of rDNA gene with reference taxa.

**Conclusions**

A total of thirty (30) laccase producing fungi, representing twenty one (21) species of fifteen (15) genera, were purified. Fifteen strains (15) with high laccase activity of basidiomycetes were identified in thirteen genera i.e., *Bjerkandera*, *Corticium*, *Coriopsis*, *Echinodontium*, *Ganoderma*, *Hexagonia*, *Irpex*, *Limonomyces*, *Psathyrella*, *Peniophora*, *Phlebiopsis*, *Trametes* and *Trichaptum*. Seven (7) *Trichoderma* and only one *Penicillium* species were found as low laccase producer, isolated from different soil and basidiocarp samples. *Trichoderma tomentosum* was recorded as most isolated laccase producing isolate from different soil samples

followed by *T. atroviride* from different regions. However, *Penicillium pinophilum* was only laccase producing species of genus *Penicillium*, isolated from soil sample of *Pinus* spp., and *Quercus* spp., dominant area.

**COMPLEX PROBIOTIC FEED SUPPLEMENT BASED ON CONSORTIUM OF MICROBIAL STRAINS FOR INDUSTRIAL POULTRY BREEDING**

N.S. Zaslauskaya<sup>1</sup>, N.V. Sverchkova<sup>1</sup>, E.I. Kolomiets<sup>1</sup>, M.I. Potapovich<sup>2</sup>,  
V.A. Prokulevich<sup>2</sup>

<sup>1</sup>Laboratory of biological control agents, Institute of Microbiology, Minsk, Belarus

<sup>2</sup>Department of Microbiology, Belarusian State University, Minsk, Belarus

**Background**

Large-scale poultry breeding often provokes outbreaks of various bacterial, viral and mixed infections leading to fowl loss, while shortage of vitamins and hardly digestible feed ingredients reduces nutritive value and downgrades commodity outlook for meat and egg products.

**Objectives**

Aim of this study – development of technology for production and application of complex probiotic feed additive possessing antimicrobial, antiviral and antioxidant action allowing to prevent and cure fowl diseases, to raise nutritive value and digestibility of fodder, to promote poultry resistance to stress factors.

**Methods**

Microbiological, biochemical, genetic engineering, physical-chemical methods were used in this research: engineering a strain-producer of chicken leukocyte alpha-interferon, submerged fermentation of microorganisms, Ispectrometry, freeze-drying and etc.

**Conclusions**

To broaden the activity spectrum of probiotic feed supplement several bacterial species capable to complement each other were applied. Active principle of the feed additive — strain *Bacillus subtilis* produces surfactins, polyene and peptide compounds displaying antagonistic activity against strictly and facultatively pathogenic microbial species colonizing avian gastrointestinal tract. It was found that *Bacillus subtilis* bacteria generate cellulases, proteases and other enzymes facilitating assimilation of fodder. Enterobacteria *Pantoea agglomerans* synthesize carotenoid pigments – sources of antioxidant activity and precursors of vitamin A in the body. The protein of chicken leukocytic alpha-interferon synthesized by *Escherichia coli* strain possesses pronounced non-specific antiviral and immune-stimulating activities.

Technology of producing complex probiotic feed supplement in dry form for poultry was developed.

Biological trials *in vitro* and *in vivo* demonstrated its safety and high efficiency in feeding experiments with broilers and hens.

**EXPLORING THE COMPLEX MICROBIAL COMMUNITY OF ACTIVATED SLUDGE SAMPLED FROM AN INDUSTRIAL TANNERY WASTEWATER TREATMENT PLANT BY ILLUMINA MISEQ.**

C. Giordano<sup>1</sup>, V. Boscaro<sup>1</sup>, A. Mannucci<sup>2</sup>, G. Munz<sup>2</sup>, G. Mori<sup>3</sup>, C. Vannini<sup>1</sup>

<sup>1</sup>*Department of Biology, University of Pisa, Pisa, Italy*

<sup>2</sup>*Department of Civil and Environmental Engineering, University of Florence, Florence, Italy*

<sup>3</sup>*Cuoioidepur, S.p.a., San Romano, Italy*

**Background**

Background: In the frame of the BIOSUR project (LIFE11 ENV/IT/075), a one-year monitoring of an industrial tannery wastewater treatment plant was performed, both from chemical-physical and biological points of view.

**Objectives**

Objectives: This study is conducted to investigate the evolution of the bacterial community of activated sludge in the same treatment plant during 2013.

**Methods**

Methods: Bacterial diversity is analyzed by the use of the Illumina MiSeq platform for sequencing hypervariable regions V3-V4 in the 16S rRNA genes. Bioinformatic analysis of the obtained 12,429,502 paired-ends reads is performed using the QIIME pipeline. The assembled 4,039,284 contigs are binned into 5,156 Operational Taxonomic Units (OTUs) that are assigned to taxonomic groups by the use of the Silva 111 database.

**Conclusions**

Conclusions: Preliminary results indicate that the bacterial diversity of active sludge is maintained at very high levels throughout the whole year. The dominant bacterial *phylum* is *Proteobacteria*, which accounts for 40%. Multivariate analysis shows that there is a discontinuity between two groups of samples. The first group, corresponding to samples collected from January to July 2013, is detached from the second group, corresponding to samples collected from September, after a period of drastic decrease of work in tanneries. The Shannon diversity index (*H*), used to calculate the diversity of bacterial communities, indicates a slight increase in the diversity level in the second period. Further analysis will better clarify the complexity

of the microbial community and the influence of specific environmental parameters on its structure and evolution.

<sup>2</sup>Archer Daniels Midland Department, Research Center Co, Decatur, USA

**Background**

Glycerol is widely used in cosmetics, food, tobacco, pharmaceutical, leather and textile industries. In addition, it is considered as a cheap raw material for microbial fermentation. That is why the construction of yeast strains-producers of glycerol became an actual objective for modern metabolic engineering. Our strategy comprised the deletion of *ADH1* gene, encoding alcohol dehydrogenase in *S. cerevisiae* and overexpression of both glycerol-3-phosphate dehydrogenase and glycerol-3-phosphate phosphatase genes (*GPD1*, *GPP2*) in order to redirect the carbon flux to glycerol instead of ethanol formation.

**Objectives**

Our goal was to design recombinant strains with deletion of *ADH1* gene combined with increased Gpd1 and Gpp2 activities.

**Methods**

Homologous recombination was used for deletion of *ADH1* gene with selective marker. The integrative module was used for expression of hybrid *GPD1-GPP2* ORF (encoding artificial fusion of both enzymes) under the control of strong constitutive promoter of the alcohol dehydrogenase gene.

**Conclusions**

Glycerol concentration during the course of fermentation was approximately 4.7-fold enhanced in a  $\Delta adh1\_GPD1-GPP2$  recombinant strain if to compare with BY4742 (2.57 g/L), reaching 12.14 g/L (0.168 g/L/h) on the third day of fermentation. Furthermore, the glycerol production in a recombinant  $\Delta adh1\_GPD1-GPP2$  strains with deletion of *ADH1* gene and overexpression of *GPD1* and *GPD2* genes was nearly 1.2-fold increase in comparison with  $\Delta adh1$  strain, which contained only the disruption of *ADH1* gene.

**MODIFICATION OF METHABOLIC PATHWAY FOR GLYCEROL PRODUCTION IN YEAST *SACCHAROMYCES CEREVISIAE***

L. Murashchenko<sup>1</sup>, K. Dmytruk<sup>1</sup>, C. Abbas<sup>2</sup>, A. Sibirny<sup>1</sup>

<sup>1</sup>Molecular Genetics and Biotechnology, Institute of Cell Biology NAS of Ukraine, Lviv, Ukraine

<sup>2</sup>Archer Daniels Midland, Research Center Co, Decatur IL, USA

**Background**

Several processes are known for the microbial synthesis of glycerol from carbohydrates that use osmotolerant yeasts, algae and a number of bacteria. However, all these utilize aerobic conditions, so the glycerol production demands air or oxygen purging throughout the fermentation, which considerably increases production costs. Therefore the development of the *Saccharomyces cerevisiae* strains capable of efficient glycerol production from glucose under anaerobic conditions is of great interest.

**Objectives**

We aimed to increase glycerol production by derepression of *ILV2* in part with *GPD1-GPP2* fused genes.

**Methods**

Homologous recombination was used for construction of the truncated version (deficient 5'-165 bp and lacking a mitochondrial targeting signal) of the yeast *ILV2* gene, encoding for acetolactate synthase with a strong constitutive promoter. Obtained strains shown increased acetolactate synthase activity. Multicopy integration module was used for expression of hybrid *GPD1-GPP2* ORF (encoding artificial fusion of glycerol-3-phosphate dehydrogenase and glycerol-3-phosphate phosphatase) under the control of strong constitutive promoter of the alcohol dehydrogenase gene.

**Conclusions**

Overexpression of the truncated version of *ILV2* with presumably cytosolic localization, strongly activates glycerol production under anaerobic conditions. Preliminary results possessed that the glycerol production by recombinant strains co-expressing *ILV2* and *GPD1-GPP2* was increased as compared to the wild type strain and strain expressing solely *ILV2*.

**AN ANTIFUNGAL PEPTIDE FROM ACTINOBACTERIA (STREPTOMYCES SP. TKJ2) : ISOLATION AND PARTIAL CHARACTERIZATION**

A. MESSIS<sup>1</sup>, A. Bettache<sup>1</sup>, N. Boucherba<sup>2</sup>, S. BENALLAOUA<sup>2</sup>, M. KECHA<sup>2</sup>

<sup>1</sup>Génie de l'environnement, Université de Bordj Bou Arréridj- Algérie,  
Bordj bou arréridj, Algeria

<sup>2</sup>Microbiology, University of A.MIRA of Béjaia, BEJAIA, Algeria

**Background**

Actinobacteria are of special biotechnological interest since they are known to produce chemically diverse compounds with a wide range of biological activity. This distinct clade of Gram-positive bacteria include some of the key antibiotic producers and are also sources of several bioactive compounds

**Objectives**

the aim of our study is the purification and the partial characterization of an antifungal protein produced by *Streptomyces* sp. TKJ2 isolated from Algerian soil.

**Methods**

A newly filamentous bacteria was recovered from Tikjda forest soil (Algeria) for its high antifungal activity against various pathogenic and phytopathogenic fungi. The nucleotide sequence of the 16S rRNA gene (1454 pb) of *Streptomyces* sp. TKJ2 exhibited close similarity (99 %) with other *Streptomyces* 16S rRNA genes. Antifungal metabolite production of *Streptomyces* sp TKJ2 was evaluated using six different fermentation media. The antifungal protein produced by *Streptomyces* sp. TKJ2 on PCA medium has been purified by ammonium sulfate precipitation, SPE column chromatography and high-performance liquid chromatography in a reverse-phase column.

**Conclusions**

The UV chromatograms of the active fractions obtained at 214 nm by NanoLC-ESI-MS/MS have different molecular weights. The F20 Peptidique fraction obtained from culture filtrat of *Streptomyces* sp. TKJ2 precipitated at 30% of ammonium sulfate was selected for analysis by infusion ESI-MS which yielded a singly charged ion mass of 437.17 Da.

**CONSORTIUM OF ANTAGONISTIC MICROBIAL SPECIES WITH HYDROLYTIC POTENTIAL AS A BASIS OF BIOPREPARATION TO PROMOTE RECOVERY OF SOIL MICROFLORA AND INCREASE CROP PRODUCTIVITY**

M. Mandryk-Litvinkovich<sup>1</sup>, T.L. Nosonova<sup>1</sup>, N.V. Sverchkova<sup>1</sup>, E.I. Kolomiets<sup>1</sup>

<sup>1</sup>Laboratory of biological control agents,

*Institute of Microbiology Belarus National Academy of Sciences, Minsk, Belarus*

**Background**

In recent years public emphasis has been focused on the problems of rapid arable land degradation: structural deterioration of ploughed layer, reduced humus content, rising acidity – all leading to loss of soil suppressive potential. Tillage quality downward trend requires urgent measures for preservation and remediation of agricultural resources. A vital method to promote soil fertility and harvests of cultivars envisages ploughing-in of straw from crop rotation precursor treated by phytoprotective microbial preparation accelerating decomposition of plant residues and regeneration of soil biocenoses.

**Objectives**

Aim of this study was to assemble a consortium of microbial species distinguished by phytoprotective and hydrolytic potential.

**Methods**

Various investigation methods were used: microbiological, biochemical, molecular-genetical.

**Conclusions**

500 microorganisms isolated from diverse natural sources were screened to yield 33 antagonists of crop soil pathogens. 3 antagonistic bacterial strains were found to show the highest levels of antimicrobial and cellulolytic activities. The selected variants were characterized by the following properties:

- growth suppression of phytopathogens belonging to genera *Fusarium*, *Botrytis*, *Colletotrichum*, *Chaetomium*, *Pseudomonas*, *Xanthomonas*;
- increased seedling/root size and crude weight;

- production of hydrolytic enzymes – endo-1,4- $\beta$ -glucanase and xylanase;
- 10-12% reduction of straw fiber content by 1 month;
- upgrading soil cellulolytic activity;
- stimulating effect on major ecologo-trophical microbial groups in soil (ammonifying, oligonitrophilic, cellulolytic, micromycetes).

The obtained data evidence attractive application prospects of microbial consortium as active ingredient of biopreparation to trying down infectious background, to reconstitute soil microbial cenoses and to promote plant growth.

**SULFUR OXIDIZING BACTERIA COMMUNITY: CHARACTERIZATION AND MONITORING IN A REACTOR FOR SULFIDE REMOVAL FROM INDUSTRIAL WASTE.**

*C. Giordano<sup>1</sup>, F. Spennati<sup>2</sup>, A. Melone<sup>1</sup>, G. Munz<sup>2</sup>, G. Mori<sup>3</sup>, C. Vannini<sup>1</sup>*

*<sup>1</sup>Biology, University of Pisa, Pisa, Italy*

*<sup>2</sup>Civil and Environmental Engineering, University of Florence, Florence, Italy*

*<sup>3</sup>Cuoidepur, Cuoidepur, Pisa, Italy*

**Background**

Tannery wastewater contains high concentrations of pollutants, mostly sulfides and sulfates, which are usually chemically removed by expensive and inefficient methods. An innovative oxidizing bioreactor for biological removal of sulfide from gaseous industrial waste streams is developed and set up in the frame of the BIOSUR project (LIFE11 ENV/IT/075).

**Objectives**

This is achieved thanks to the development of a specialized chemolithoautotrophic sulfur-oxidizer biomass, which has been studied in order to elucidate its evolution.

**Methods**

The involved microbial community is selected in a side reactor by incremental addition of sulfides in selective conditions: low pH (2-4) and a concentration of sulfides of 2-4 mg/l. Such a specialized biomass was characterized and monitored by means of T-RFLP fingerprinting, clone-library construction of 16S rRNA coding genes and isolation in pure culture.

**Conclusions**

Preliminary results show the evolution of a selected, specialized sulfur-oxidizer biomass from the onset of the reactor to the stationary phase. In this scenario, about 65% of screened clones are represented by bacteria whose 16S rRNA gene sequence shows a similarity higher than 97% with that of members of the genus *Halothiobacillus*, well-known as Sulfur Oxidizing Bacteria (SOB). The same results has been also confirmed by isolation in SOB selective medium. Finally, obtained data have been comparatively analyzed in order to monitor microbial community evolution from the start-up throughout the end of the experiment.

## **IMPROVEMENT OF GLUTATHIONE PRODUCTION IN METHYLOTROPHIC YEAST *HANSENULA POLYMORPHA***

M. Yurkiv<sup>1</sup>, M. Yurkiv<sup>1</sup>, O. Kurylenko<sup>1</sup>, K. Dmytruk<sup>1</sup>, A. Sibirny<sup>1</sup>

<sup>1</sup>*Molecular Genetics and Biotechnology, Institute of Cell Biology NAS of Ukraine, Lviv, Ukraine*

### **Background**

Glutathione ( $\gamma$ -L-glutamyl-L-cysteinyl-glycine; GSH) is the most abundant non-protein thiol compound of the most living organisms that protects cells from environmental and oxidative stresses. This tripeptide is an important natural compound for medicine, biotechnology and food industry. Microbial GSH overproduction is limited by mechanisms of feedback inhibition of  $\gamma$ -glutamylcysteine synthetase (GCS), the first and rate-limiting enzyme of GSH biosynthesis, by the end product. In addition the expression of gene coding for GCS is repressed by GSH. Thermotolerant methylotrophic yeast *H. polymorpha* is considered as promising organism for genetic modification and design of competitive GSH producer.

### **Objectives**

To obtain a competitive producer of GSH in methylotrophic yeast *H. polymorpha* by overexpression of modified GCS with eliminated repression-inhibition mechanisms normally exerted by GSH.

### **Methods**

Standard methods of yeast molecular genetics, yeast biochemistry and physiology have been used. The modified versions of *GSH2* gene were obtained by error prone PCR.

### **Conclusions**

The modified versions of *GSH2* gene obtained by error prone PCR were cloned under the control of strong constitutive promoter of glyceraldehyde-3-phosphate dehydrogenase in replicative plasmid pYT3. Selected transformants were analyzed for their resistance to different prooxidant agents (1,2,3-triazole, diethylmaleate, ethionine) as compared to strains carrying unmodified *GSH2* gene. Selected strains possessed growth on medium supplemented with triazole. Strains providing more intensive growth on the selective medium revealed higher GSH accumulation as compared to strains carrying unmodified *GSH2* gene, indicating the reduction of Gsh2 feedback inhibition. In this work the selection scheme providing generation of

Gsh2 insensitive to feedback inhibition was developed.

**HOW TO INTERPRET GENOMIC UNITS INSTEAD OF COLONY FORMING UNITS:  
A CASE STUDY WITH LEGIONELLA PNEUMOPHILA**

L. Vanysacker<sup>1</sup>, L. De Coster<sup>1</sup>, J. Boonen<sup>1</sup>

<sup>1</sup>Centraal Laboratorium, De Watergroep, Heverlee, Belgium

**Background**

*Legionella pneumophila* has been proven to be the causative agent of the potential deadly Legionnaires' disease since 1977. In most of the European countries, the reference method for enumeration of *Legionella* in water is culture (ISO 11731). Due to the long incubation time of this method, more and more laboratories use quantitative PCR (qPCR). Since 2012 the normalization for the *Legionella* qPCR increases considerably: the ISO 12869 was developed, there exist different interlaboratory tests and reference standards. Different reports showed that this technique is accurate enough to be implemented as a reference method. One remaining obstacle is the data interpretation: the culture is expressed in colony forming units (CFU) and the qPCR in genomic units (GU). Although there is a correlation between both units, there is no consensus on how GU can be translated to CFU.

**Objectives**

Based on a database of hot and cold sanitary water samples and a literature screening an action level was defined for the monitoring of *Legionella* in sanitary water.

**Methods**

200 water samples were analyzed by culture and qPCR following the ISO 11731 and ISO 12869 respectively. A correlation analysis was performed and the variance was calculated by the logarithmic differences between the culture and the qPCR results. Together with the results from literature, action levels for the *Legionella* monitoring are proposed.

**Conclusions**

Although the culture has been widely used for many years, one should consider the advantages of qPCR over culture and acknowledge its suitability as a reference method.

**A NOVEL BETA-GALACTOSIDASE FROM ARTHROBACTER SULFONIVORANS:  
PURIFICATION, CHARACTERIZATION AND GENE CLONING**

A. Kastsianevich<sup>1</sup>, L. Sapunova<sup>2</sup>

<sup>1</sup>Laboratory of experimental mycology and biodeterioration,  
Institute of Microbiology Belarus National Academy of Sciences, Minsk, Belarus

<sup>2</sup>Laboratory of enzymes,  
Institute of Microbiology Belarus National Academy of Sciences, Minsk, Belarus

**Background**

**Beta-galactosidase** (EC 3.2.1.23) also known as lactase is the enzyme that typically catalyzes hydrolysis of beta-1,4-D-galactosidic linkages in beta-D-galactosides, including disaccharide lactose, with glucose and galactose as end reaction products. This enzyme is able to catalyze synthesis of oligosaccharides, in particular galactooligosaccharides via galactosyl transfer reaction.

*Arthrobacter sulfonivorans* beta-galactosidase of unique for prokaryotes extracellular localization may find application in food industry for manufacturing lactose-free dairy products and in pharmacology as bioactive principle of medicines prescribed for patients suffering from lactase deficiency.

**Objectives**

The study was aimed at cloning of the gene encoding *A. sulfonivorans* beta-galactosidase, purification and characterization of the enzyme.

**Methods**

Fast protein liquid chromatography, electrophoretic analysis, enzyme assay, PCR, DNA sequencing.

**Conclusions**

A novel extracellular beta-galactosidase from *A. sulfonivorans* was recovered with an overall 207-fold purification, a 7.7% yield and specific activity 16 300 U·mg<sup>-1</sup> protein. The subunit molecular mass of the enzyme determined by SDS-PAGE analysis equalled 125 kDa. It was found that the enzyme displays pI 5.35, prefers ortho-nitrophenyl-beta-galactoside as substrate (K<sub>m</sub> 27 mM) and shows maximum activity at 40°C and at pH 7.5–9.5.

The beta-galactosidase gene was isolated from the genomic DNA library of *A. sulfonivorans*, sequenced, cloned and deposited in the GenBank database under

accession number KM277894.1. It was established that the gene carries an open reading frame consisting of 3132 bp (1043 amino acids) and encodes beta-galactosidase referred to Glycosyl Hydrolase Family 2 (CAZy database).

**FUNCTIONALITY ANALYSIS OF STRUCTURAL DOMAINS FROM GD-95 LIPASE BY SITE SPECIFIC AND RANDOM MUTAGENESIS**

R. Gudiukaitė<sup>1</sup>, A. Gegeckas<sup>1</sup>, V. Malūnavičius<sup>1</sup>, D. Čitavičius<sup>1</sup>

<sup>1</sup>*Microbiology and Biotechnology, Vilnius University, Vilnius, Lithuania*

**Background**

The rapid evolution of bioconversion and ecotechnology strongly increases the focus on the enzymes which possess novel properties. One of the most interesting enzymes are lipases from *Geobacillus* bacteria, because they can be active at extreme conditions. The ability to manipulate these lipases depends on the knowledge about the importance on the functionality of their individual domains and amino acids.

**Objectives**

Determination of influence conservative amino acids located at C-terminal end on activity GD-95 lipase without 10 C-terminal amino acids (GD-95-10) and construction new GD-95 lipase variants using error-prone PCR.

**Methods**

Lipase from *Geobacillus* sp. 95 without 10 C-terminal acid was analyzed by Ala scanning mutagenesis. New variants of recombinant GD-95 lipase were created using several error-prone PCR (epPCR). Ala mutants and GD-95 lipase variants after epPCR were cloned into pTZ57R/T and pET-21c(+) vectors. The recombinant proteins were expressed in *Escherichia coli* BL21(DE3) and purified using affinity chromatography. The activity and thermostability analysis of new lipases was performed spectrophotometrically.

**Conclusions**

GD-95-10 lipase was analyzed in this work using Ala mutagenesis. New results confirmed, that higher influence on activity and functionality of GD-95-10 lipase make Asp371 and Tyr376. Also the new GD-95 lipase variants were created using epPCR. The analysis of lipases obtained after random mutagenesis was showed that only a few changes in amino acids sequence can result new physicochemical properties of *Geobacillus* lipases. Therefore our results are basis for further enzyme engineering experiments and for creation of new lipases for bioconversion and ecotechnology.

**USE OF SIGMA FACTORS FROM BACILLUS SUBTILIS IN THE DEVELOPMENT OF AN ORTHOGONAL EXPRESSION SYSTEM IN ESCHERICHIA COLI.**

I. Bervoets<sup>1</sup>, M. De Mey<sup>2</sup>, D. Charlier<sup>1</sup>

<sup>1</sup>Research group of Microbiology, Vrije Universiteit Brussel, Brussels, Belgium

<sup>2</sup>Centre of Industrial Biotechnology and Biocatalysis, Universiteit Gent, Ghent, Belgium

**Background**

Technological advances in synthetic biology, systems biology, and metabolic engineering have boosted applications of industrial biotechnology for an increasing number of complex and high added-value molecules. In general, the transfer of multi-gene or poorly understood heterologous pathways into the production host leads to imbalances due to lack of adequate regulatory mechanisms. Hence, fine-tuning expression of synthesis pathways in specific conditions is mandatory.

**Objectives**

Here we develop a new genetic circuit for regulated expression specifically in stationary phase due to clear advantages during this period (reduction of toxicity, competition).

**Methods**

This circuit consists of a heterologous sigma factor ( $\sigma$ ) recognizing specific promoter sequences, which are not recognised by the native  $\sigma$  factors of *E. coli* and is expressed upon entering the stationary phase. First, several  $\sigma$  factors of *B. subtilis* were tested for their orthogonality in *E. coli* on the level of promoter recognition, by using a red-fluorescent reporter system. Secondly, the potential of  $\sigma$  factors of *B. subtilis* to work together with the *E. coli* core RNA polymerase was tested, by expressing these proteins together with their promoters. Based on the results a specific factor will be chosen for further optimisation and the corresponding gene can be cloned in the  $\sigma_S$  factor operon of *E. coli*, which is most abundantly expressed in stationary conditions.

**Conclusions**

Combining all these elements should allow us to create an orthogonal genetic circuit that is able to transcribe specific genes under stationary phase with a limited influence on the host cell's metabolism.

## **COMPARISON OF POLYETHYLENE TEREPHTHALATE DEGRADING POLYESTER HYDROLASES FROM ACTINOMYCETES**

J. Schmidt<sup>1</sup>, R. Wei<sup>1</sup>, T. Oeser<sup>1</sup>, M. Barth<sup>1</sup>, J. Then<sup>1</sup>, W. Zimmermann<sup>1</sup>

<sup>1</sup>Microbiology and Bioprocess Technology,  
Institute of Biochemistry University of Leipzig, Leipzig, Germany

### **Background**

Polyethylene terephthalate (PET) is a synthetic aromatic polyester that is degraded by several hydrolases from actinomycetes. The heterogeneous enzymatic PET hydrolysis occurs at mild temperature and pH conditions and offers an environmentally friendly alternative to chemical plastic recycling processes. LC cutinase, TfCut2 and Cut190 are homologous polyester hydrolases produced by actinomycetes obtained from a compost metagenome, from *Thermobifida fusca* KW3 and *Saccharomonospora viridis* AHK 190, respectively.

### **Objectives**

The enzymatic degradation of PET films by the three polyester hydrolases was compared at various reaction conditions to evaluate the effects of buffer composition, pH, ionic strength and metal ions on their enzymatic activity.

### **Methods**

Genes coding for LC cutinase, TfCut2 and Cut190 were cloned into pET-20b(+) vector for heterologous protein expression in *Escherichia coli* BL21(DE3). Purified enzymes were used to degrade PET films at 60 to 70 °C for 1 to 50 h in different buffer systems as well as in the presence of Ca<sup>2+</sup> and Mg<sup>2+</sup>. The released products were analyzed by reversed phase high performance liquid chromatography. The weight losses of PET films following an enzymatic hydrolysis by the different enzymes were determined gravimetrically.

### **Conclusions**

The LC cutinase from the compost metagenome and TfCut2 from *T. fusca* showed significantly higher PET hydrolytic activity compared to Cut190 from *S. viridis*. The addition of both Ca<sup>2+</sup> and Mg<sup>2+</sup> stabilized the enzymes and thus facilitated an effective PET degradation. The enzymatic activity of the polyester hydrolases against PET films was strongly depending on the type and ionic strength of the selected buffer.

## **A DISRUPTIVE INNOVATION FOR AMBIENT TEMPERATURE PRESERVATION OF MICROORGANISMS**

A.L. Fabre<sup>1</sup>, A. Luis<sup>2</sup>, D. Clermont<sup>3</sup>, S. Keller<sup>1</sup>, C. Bizet<sup>3</sup>, S. Tuffet<sup>1</sup>, J. Bonnet<sup>4</sup>

<sup>1</sup>R&D, Imagene, Evry, France

<sup>2</sup>R&D, Imagene, Bordeaux, France

<sup>3</sup>Département de microbiologie- Collection de l'Institut Pasteur, Institut Pasteur, Paris, France

<sup>4</sup>U916, Institut Bergonié, Bordeaux, France

### **Background**

Because of the increase in the number of samples of microorganisms to be stored and shipped, classical preservation in freezers, subjected to risks of technical failure, is becoming more and more costly in space, energy and maintenance. Freeze-drying offers an alternative to cold preservation. However, it is time-consuming and requires precise cycle adjustments. Moreover, glass vials are subjected to breakage and can become leaky resulting in decrease in bacterial viability over time. Imagene innovation aims at preserving dehydrated bacteria at ambient temperature (AT) in hermetic minicapsules that maintain an anoxic and a low-controlled humidity environment. The minicapsules are resistant to impacts and have a unique, engraved datamatrix code allowing a tamper-proof traceability of the samples.

### **Objectives**

This study aims at demonstrating the effectiveness of a novel and rapid process for a reliable long term AT storage of microbial strains.

### **Methods**

Two bacteria, *Pantoea dispersa* and *Aeromonas Salmonicida*, a freeze-drying sensitive strain, were desiccated by evapo-concentration in presence of different stabilization solutions and encapsulated in minicapsules, which were stored either at AT or 37 °C (long-term storage simulation). Bacteria were recovered by simple rehydration.

### **Conclusions**

The residual viability rates post-dessication were ~80 % for *P. dispersa* and ~60 % for *A. salmonicida*. Both strains kept a residual viability rate >50 % after 4 weeks at 37 °C and at AT in Imagene minicapsules. Viability rates following Imagene process were comparable to that of freeze-drying. In conclusion, our work demonstrated that this new process is suited to AT preservation of bacteria.

## **THE HIGH EFFICIENCY FUNGUS (ANTRODIA CINNAMOMEA) FERMENTER FOR TRITERPENOID PRODUCTION**

J.T. Kuo<sup>1</sup>, C.C. Lin<sup>2</sup>, Y.Y. Lin<sup>2</sup>, J.T. Lee<sup>2</sup>, Y.C. Chang<sup>1</sup>, Y.C. Chung<sup>1</sup>

<sup>1</sup>Department of Biological Science and Technology,  
China University of Science and Technology, Taipei city, Taiwan

<sup>2</sup>Department of Biotechnology, Taiwan Leader Biotech Corp., Taipei city, Taiwan

### **Background**

*Antrodia cinnamomea* grows only on *Cinnamomun kanehirai* Hay (host specificity) and it is a unique fungus in Taiwan. In recent studies, the major components of *Antrodia cinnamomea* are triterpenoids whose functions were anti-inflammation and anti-cancer. So it is a valuable fungus in pharmaceutical potential. However, *Antrodia cinnamomea* grows slowly and does not obtain the fruiting body form easily under artificial cultivation.

### **Objectives**

Based on this consideration, this study modified the plant factory as the new fungus fermenter to increase the triterpenoids products.

### **Methods**

We isolated the new *Antrodia cinnamomea* strain (CUST-AC901) from the trees in the mountainous areas of *Hualien* in Taiwan. It was fermented on this new established fermenter without light, which is one type of closed plant production systems (CPPS) consisting of a thermally insulated, air conditioners, a CO<sub>2</sub> and nutrient solution supply unit. The triterpenoids were analyzed by HPLC.

### **Conclusions**

We established a new high-efficient solid-state cultivation with CUST-AC901 strain and obtained the optimal conditions (temperature at 20°C, CO<sub>2</sub> at 10%, humidity at 85%, and with 1% peptone in whole grains medium). We also obtained compositions on fruiting bodies similar to the wild ones. It only took two months and reduced the producing cost. With HPLC analysis, we confirmed that total triterpenoids products were increased by four-folds than they were under traditional culture method. To our knowledge, this is the first report to omni-functional solid-state fermenter with high triterpenoids product efficiency and low cost as well as reaching to automatic mass production without expensive automatic production equipment.

<sup>1</sup>Department of Molecular Genetics and Biotechnology,  
Institute of Cell Biology NAS of Ukraine, Lviv, Ukraine

<sup>2</sup>Department of Biotechnology and Microbiology, University of Rzeszow, Rzeszow,  
Poland

**Background**

Lignocellulose is currently considered as the most promising renewable feedstock for production of liquid biofuels. Xylose is the second most abundant sugar in nature, being a component of hemicellulose, which is in turn a part of lignocellulose. Yeasts and most of mycelial fungi can metabolize xylose by the so called xylose reductase – xylitol dehydrogenase pathway including xylose reduction to xylitol and subsequent xylitol oxidation to xylulose which is then phosphorylated by a specific kinase and enters pentose phosphate pathway (PPP). A simultaneous improvement of xylose conversion to xylulose and in the activities of PPP enzymes is required for efficient xylose utilization in different microorganisms. Xylose fermenting yeast *Hansenula polymorpha* contains in addition to cytosolic transaldolase (gene *TAL1*) and transketolase (gene *TKL1*) also peroxisomal transketolase (also known as dihydroxyacetone synthase, gene *DAS1*) and putative peroxisomal transaldolase (gene designated by us as *TAL2*).

**Objectives**

To investigate the role of cytoplasmic and peroxisomal transaldolase and transketolase in xylose metabolism and alcoholic fermentation in *H. polymorpha*.

**Methods**

Molecular-biology techniques

**Conclusions**

In the wild type strain of *H. polymorpha* overexpression of *DAS1* and *TAL2* turned out to be beneficial for xylose alcoholic fermentation. Moreover, mutants with knock out of at least one of these genes were impaired in xylose fermentation as compared to the

wild-type strain. To investigate the role of cytosolic transaldolase and transketolase in xylose metabolism of *H. polymorpha* recombinant strains overexpressing *TAL1* and *TKL1* genes were constructed. However, such strains revealed no substantial difference in ethanol production as compared to the wild-type strain.

**Biotechnology and industrial microbiology**

## **WOOD FOR FOOD: AVAILABLE METHODS FOR MICROBIAL HAZARD ANALYSIS**

*F. AVIAT<sup>1</sup>, R. Ismail<sup>1</sup>, I. LE BAYON<sup>2</sup>, V. MICHEL<sup>3</sup>, M. JEQUEL<sup>2</sup>, M. KUTNIK<sup>2</sup>, M. FEDERIGHI<sup>1</sup>*

<sup>1</sup>UMR INRA 1014 SECALIM, Oniris INRA, Nantes, France

<sup>2</sup>FCBA Laboratoire de biologie, FCBA Bordeaux, Bordeaux, France

<sup>3</sup>Actalia, Actalia produits laitiers, La Roche sur Foron, France

### **Background**

Wood is a direct food contact material used in the food industry since ancestral times. In Europe, wooden food contact surfaces are subject to the European regulation n°1935/2004, which specifies that food contact material must not interfere with foodstuff characteristics (Anonymous, 2004).

Today, no standard recovery method was defined for wooden food contact surface. Therefore, it might be important to provide an efficient method to quantify the microbial load on the wooden surfaces in direct contact with food.

### **Objectives**

The aim of this study was to compare three methods of recovering microorganisms from wooden surfaces: grinding, brushing and planing (Ismail et al., 2014).

### **Methods**

Three microorganisms, well-known as risk along the food chain, were tested: *Listeria monocytogenes*, *Escherichia coli* and *Penicillium expansum*. We chose three wooden species - pine, poplar and spruce - which are mainly used to manufacture wooden packaging. We analyzed the influence of wooden moisture content, contact time and wood timbers on microbial recovery rates.

### **Conclusions**

We identified that factors cited above influenced the microbial recovery rates from wooden surfaces. Grinding was the most reliable method with the best recovery yield: 30.1 % for *Listeria monocytogenes* on spruce and *Escherichia coli* on poplar, and 30.4% for *Penicillium expansum* on poplar. Planing was chosen to be applied to thicker wooden as cheese ripening shelves and tested, then, for analyzing the microbial load of 54 various wooden ripening shelves. We did not found common

pathogens known as risks for dairy products. Our results suggest that wood is suitable for food contact.

**FEMS-1406**

**Biotechnology and industrial microbiology**

**PROMOTER STRENGTH AND PLASMID LOSS IN SACCHAROMYCES CEREVISIAE STRAINS EXPRESSING LIPASE A FROM BACILLUS SUBTILIS**

*R. Sanz Gil<sup>1</sup>, M. Mormeneo Iranzo<sup>1</sup>, J. Zueco<sup>1</sup>*

<sup>1</sup>*Microbiology. Fac Pharmacy, University of Valencia, Burjassot, Spain*

**Background**

GRAS status, the availability of different types of mutants and the ability to perform eukaryotic post-translational modifications, including complex glycosylation and protease processing, make *Saccharomyces cerevisiae* an ideal host for the expression of recombinant proteins. Among recombinant enzymes, lipases are used in many different industrial applications including pharmaceutical synthesis, biodiesel production, detergent formulation and food industry.

**Objectives**

In the present work, lipase A from *Bacillus subtilis* was expressed in the *S. cerevisiae* CEN.PK113-5D strain as a fusion protein with the yeast cell-wall mannoprotein Pir4. In order to compare the effect of different promoters on the levels of lipase activity secreted into the growth medium, three different YEplac195 based constructions were created, differing only in the promoter controlling the expression of the gene fusion; the original weak and constitutive PIR4 promoter, the TEF1 promoter, strong and constitutive, and the inducible GAL1 promoter.

**Methods**

The resulting three strains were grown in rich non-selective medium and the levels of secreted lipase activity and plasmid loss were determined after 48 hours of growth.

**Conclusions**

Our results show that the use of a very strong constitutive promoter is a poor strategy, since plasmid loss occurs in over 80% of cells and consequently total activity levels remain low in comparison with the strain transformed with the construction including a weaker promoter, where plasmid loss occurs in around 20% of cells. Finally, maximum levels of activity were achieved using the GAL1 promoter in conditions of induction for 24 hours after 24 hours growth in non-inducing conditions.

**ENGINEERED SALMONELLA ENTERICA TYPHIMURIUM CONTROLS TUMOR GROWTH IN MURINE MELANOMA MODEL**

C.H. Werle<sup>1</sup>, G.P. Milanez<sup>1</sup>, J. Pastorello<sup>1</sup>, F. Moraes<sup>1</sup>, B. Leite<sup>1</sup>, M. Brocchi<sup>1</sup>

<sup>1</sup>*Genetics Evolution and Bioagents, State University of Campinas, Campinas, Brazil*

**Background**

The cancer is the second most frequent cause of death. Melanoma, a malignancy that arises from melanocytes, accounts for approximately 10% of skin tumors and in recent years its incidence has increased. The mortality rate currently stands at 80%, while 5-year survival rate is less than 5%. The factors that affect cancer outcomes, such as disease recurrence, risk of second malignant neoplasms, and the late effects of cancer treatments, becomes more important. For almost 200 years has been known that bacteria have the ability to colonize solid tumors and induce tumor shrinkage. The bacteria *Salmonella enterica* Typhimurium are facultative anaerobes and has a particular promise as a cancer therapeutic because it can be manipulated and has been shown to preferentially accumulate in tumors compared with other organs after systemic injection. *S. enterica* strains can have the anti-tumor activity enhanced by genetic manipulation

**Objectives**

This study aims to evaluate the anti-tumor potential of attenuated new mutants of *S. Typhimurium* in murine models.

**Methods**

Six –week-old female C57Bl/6 mice were subcutaneously injected with  $5 \times 10^5$  B16F10 (murine melanoma). After 12 days mice were injected intratumoral with  $10^7$  CFU/mL of *S. enterica* LGBM127.

**Conclusions**

Our results showed a reduction in tumor growth and an increased survival rate in mice treated with *S. enterica* when compared to the control group (PBS). There were no signs of prostration after LGBM127 inoculation. More tests are needed, but our preliminary data demonstrate a high potential for the use of the attenuated strain of *S. Typhimurium* as antitumor agents.

**PROTEIN ENGINEERING TO INCREASE THE THERMOSTABILITY AND ACTIVITY OF THE GH-10 XYLANASE FROM THERMOASCUS AURANTIACUS, BY SITE-DIRECTED MUTAGENESIS**

A. Silva<sup>1</sup>, J.A. Mertens<sup>2</sup>, R. Da Silva<sup>1</sup>, E. Gomes<sup>1</sup>

<sup>1</sup>Biochemistry and Applied Microbiology Laboratory, Universidade Estadual Paulista-Unesp, Sao Jose do Rio Preto, Brazil

<sup>2</sup>Bioenergy Research Unit, National Center for Agricultural Utilization Research, Peoria, USA

**Background**

The enzymatic saccharification of lignocellulosic biomass and biobleaching paper pulp are attractive strategies for the bioprocess industry where xylanases have been heavily applied. These processes require enzymes that tolerate high stress environmental conditions such as extreme temperatures. The wild xylanase from *T. aurantiacus* (xynA) has been described as a potential enzyme for rational protein engineering studies. In the first step of this study, two no silent mutations were detected in the xynA sequence, cloned in *S. cerevisiae* strain, and it may explain the reduced expression and activity.

**Objectives**

New strategy was proposed to overcome the expression issues and enzyme improvement. First, xynA gene was rebuilt and it was used as template for constructions of mutants by site-directed mutagenesis (SDM) to increase thermal tolerance and activity.

**Methods**

For this, the original gene was amplified and cloning into pET28a. For the SDM reactions were used the Q5® SDM Kit. Primers were constructed according to the desired mutations and each one used for its changing. In the total, 13 reactions were prepared, in wich only the first two were done to the reconstruction of xynA. All the mutagenic xylanases were characterized in pH (3.5-10) and Temperature (40-80°C) by enzymatic assay.

## **Conclusions**

Regarding the optimum temperature, the enzymes are active at 65°C, and pH 5. About the stability temperature, the most of them are stable from 40°C to 65°C, and four mutants until 75°C, both in wide range of pH. These results helped the selection of the best mutagenic xylanases for future assays.

## **NOVEL BIOINSECTICIDES BASED IN BACILLUS THURINGIENSIS SPORES TO CONTROL PLAGUE DISEASES IN PLANTS**

R. Grau<sup>1</sup>, C. Leñini<sup>1</sup>, M. Bartolini<sup>1</sup>, S. Buelva<sup>2</sup>, M. Abalo<sup>3</sup>, G. Gonzalez Anta<sup>3</sup>

<sup>1</sup>Microbiology, Universidad Nacional de Rosario - CONICET, Rosario, Argentina

<sup>2</sup>Microbiology, Universidad Nacional de Rosario, Rosario, Argentina

<sup>3</sup>Microbiology, Rizobacter S.A., Pergamino, Argentina

### **Background**

The massive use of synthetic chemical agents of biocontrol (i.e. insecticides) with potential toxicity to the users and the environment pushes for the development of alternative (ecological and natural) compounds. To this respect, the use of natural and human-friendly bacteria with insecticide (i.e. larvicide) activities (biocontrol agents) represents an interesting alternative.

### **Objectives**

*Bacillus thuringiensis*, is a ubiquitous Gram-positive, spore-forming bacterium that forms soluble Vip toxins and a parasporal crystal (Cry toxin) during its growth cycle. These *B. thuringiensis* toxins are efficient for the control of certain plant-detrimental insect species among the orders *Lepidoptera*, *Diptera*, and *Coleoptera*.

### **Methods**

One hundred nineteen *B. thuringiensis* strains isolated from different agricultural regions of Argentina were characterized for Vip and crystal protein production and evaluation of toxicity against Lepidopteran insect's larvae. Finally the genomic sequencing of the 16S ribosomal subunit genes plus the PCR identification of *cry* and *vip* subclasses of selected isolates were performed.

### **Conclusions**

Several of the novel isolates were able to simultaneously control *Spodoptera frugiperda* and *Rachiplusia n̄u* larvae under laboratory and open field conditions. Interestingly, many of the isolates harbored both insecticidal genes (*vip*, *cyt*). The role of the master transcription regulator Spo0A on insecticidal protein production is presented. The understanding of the genetic network under Spo0A command opens new avenues for the development of intelligent biocontrol agents in the scope of integrated pest management for sustainable agriculture.

<sup>2</sup>Microbiology, Universidad Nacional de Rosario - FONCyT, Rosario, Argentina

<sup>3</sup>Microbiology, Biotay S.A., Buenos Aires, Argentina

**Background**

Many problems associated with haymaking would be solved by reducing hay-drying time or if hay could be stored at high moisture without fungal spoilage. Bacterial inoculants are an ecological alternative for improving hay (and silage) preservation.

**Objectives**

The aim of this study was to identify, isolate and select the best spore-forming *Bacillus* strains capable of inhibiting the growth of undesirable fungus and accelerate the dehydration of forage in order to conserve its original nutritional value.

**Methods**

Seventy *Bacillus* strains were isolated from alfalfa fields of Argentina. Small bales and open field assays were prepared and treaded with each *Bacillus* strain in absence and presence of *Fusarium verticillioides*. These bales were daily monitored throughout the trial for evidence of mold growth, dehydration of alfalfa and bale organoleptic quality. Germination rates / outgrowth and biofilm / spreading were evaluated in AFGK-buffer and LB medium, respectively. Genomic identification of selected isolates was performed by sequencing of the gene coding for the 16S ribosomal RNA. Five isolates (initially identified as *B. subtilis*, *B. pumilus* and *B. amyloliquefaciens*) showed a broad spectrum of fungal control and an accelerated dehydrating capacity of alfalfa that improved the retention of its nutritional values in the forage. Viable spores were showed to be needed for these effects and the capacity of alfalfa colonization by mechanisms of biofilm formation and spreading were identified.

**Conclusions**

The novel *Bacilli* presented in this work, and the understanding of the displayed molecular mechanisms, are suitable for the production of novel inoculants to conserve forages of high nutritional value.

## **GENE DISRUPTION ANALYSIS FOR ETHANOL PRODUCTION IN GLYCEROL FERMENTATION IN GLYCEROL-ASSIMILATING KLEBSIELLA VARIICOLA AND ITS METABOLIC CHANGES**

T. Suzuki<sup>1</sup>, K. Seta<sup>1</sup>, T. Nakajima-Kambe<sup>1</sup>

<sup>1</sup>Faculty of Life and Environmental Sciences, University of Tsukuba, Ibaraki Tsukuba, Japan

### **Background**

The gram-negative enteric bacterial genus *Klebsiella* can utilize glycerol as a sole carbon source and is known to produce some valuable metabolites, such as ethanol and 1,3-propanediol (1,3-PD). Previous studies, we have obtained streptomycin-resistance *K. variicola* mutant, strain TB-83D, as an ethanol producer from glycerol, and have demonstrated that it showed higher ethanol production than parent strain (Suzuki et al. Bioresour. Technol. 2015.). To further increase ethanol productivity, metabolic changes and inhibition of byproduct production by gene disruption were required.

### **Objectives**

To further improve ethanol production, the aim of this study is to increase gene induction efficiency for gene disruption and to suppress byproduct production by gene disruption.

### **Methods**

Gene disruption was performed by using modified Red recombination method. Metabolite concentrations were measured by HPLC (Waters alliance 2695) and F-kit D-/L-lactic acid (Boehringer Mannheim).

### **Conclusions**

Since strain TB-83D produced mainly D-lactate under optimum conditions, we considered that suppression of D-lactate production is effective in improving ethanol production. To suppress D-lactate production, we disrupted lactate dehydrogenase gene (*ldhA*) by Red recombination. Gene disruption efficiency of *Klebsiella* species is low than that of other *Enterobacteriaceae* family. Therefore, we modified the conventional Red recombination, and succeeded in improvement of gene disruption efficiency. Although *ldhA* disruptant did not produce lactate in glycerol fermentation, ethanol production increased than TB-83D. Metabolic flux analysis and metabolic changes are in progress to optimize the ethanol production process, the results of which will be described in detail in due course.

**DESIGN OF SACCHAROMYCES CEREVISIAE PRODUCING CELLULOSOME-BASED CELLULOLYTIC ENZYME COMPLEXES FOR LIGNOCELLULOSIC BIOMASS UTILIZATION**

J.E. Hyeon<sup>1</sup>, D.H. Kang<sup>1</sup>, S.K. You<sup>1</sup>, S.O. Han<sup>1</sup>

<sup>1</sup>Biotechnology, Korea University, Seoul, Korea

**Background**

Heterogeneous structure of lignin imparts plants with structural rigidity and also serves to protect cellulose and hemicellulose from degradation. Thus, prior to fermentative production of ethanol from the cellulose by yeast strains, the materials are degraded and hydrolyzed to release monomeric sugars.

**Objectives**

In this study, designer cellulosome was assembled in yeast *Saccharomyces cerevisiae* for utilizing of cellulose as the substrate. For utilizing of cellulose part in lignocellulosic biomass by simultaneous saccharification and fermentation, a recombinant scaffolding protein from *Clostridium cellulovorans* and a chimeric endoglucanase E from *Clostridium thermocellum* were assembled as complex system. Compared to the results for single subunit, assembly of cellulosome-based enzyme complexes caused a noticeable increase such as 2.1-fold-higher in the level of enzyme activity. The resulting strain was able to ferment cellulose part in pretreated barley straw into ethanol with the aid of beta-glucosidase A from *C. thermocellum*. In the fermentation assay at 10 g/L initial substrate, approximately 2.1-folds higher ethanol than that of wild type was produced.

**Methods**

The use of complexed enzyme systems is one of the strategies for effective lignocellulosic biomass hydrolysis. Enzyme complexes were formed via the interaction of a dockerin domain with cohesin modules in the scaffolding protein.

**Conclusions**

Accelerating the biological degradation of lignocellulosic materials will benefit from the development of useful recombinant enzymes with hydrolysis ability. In future research, construction of designer enzyme complexes containing other lignin degrading enzymes could be used to develop biocatalysts that can completely degrade lignocellulose into single sugars.

**CHARACTERIZATION OF PHYSIOLOGICALLY ACTIVE COMPOUNDS AND CO<sub>2</sub> REDUCTION IN RHODOBACTER SPHAEROIDES MUTANT STRAINS**

J. Park<sup>1</sup>, Y. Kim<sup>2</sup>, J. Min<sup>1</sup>

<sup>1</sup>Division of Chemical Engineering, Chonbuk National University, Jeonju, Korea

<sup>2</sup>Department of Microbiology, Chungbuk National University, Cheongju, Korea

**Background:**

The purple nonsulfur photosynthetic bacteria, *Rhodobacter sphaeroides*, are capable of growing under a variety of environmental conditions. Particularly this microorganism can use carbon dioxide as a carbon source to grow. In addition, this bacterium also has the capability to produce all kinds of the polyphenol, nucleic acid material, vitamin, bio-active substances and polyhydroxybutyrate (PHB). Therefore, this study focused on analyzing the properties of organic compounds and reduction of CO<sub>2</sub> in *R. sphaeroides* mutant strains.

**Objectives:**

In this study, relying on the ability to produce physiologically active compounds (PACs) and reduce CO<sub>2</sub>, four different chemically mutated strains: *R. sphaeroides* KCTC 1434, MBTLJ-8, MBTLJ-13 and MBTLJ-20 were screened in order to select the most optimal strain.

**Methods:**

*R. sphaeroides* KCTC 1434, MBTLJ-8, MBTLJ-13 and MBTLJ-20 that are all chemically mutated strains, were used in this study. To be more precise, the comparison among these strains in terms of their ability to produce physiologically active compounds (PACs) and reduce CO<sub>2</sub> was carried out.

**Conclusions:**

The result showed that the mutant strain MBTLJ-8 performed the best ability of CO<sub>2</sub> fixation. In addition, it also showed that the CO<sub>2</sub> reduction and cell growth of mutant strains enhanced under the blue colored light emitting diode (LED) conditions. Therefore, our data indicated that the wave length of special light probably affected the cell growth, CO<sub>2</sub> reduction and organic compounds production of mutant strains.

## **EFFECT AND ANALYSIS OF RHODOBACTER SPHAEROIDES EXTRACT UNDER VARIOUS CULTURE CONDITIONS**

J. Park<sup>1</sup>, Y. Kim<sup>2</sup>, J. Min<sup>1</sup>

<sup>1</sup>Division of Chemical Engineering, Chonbuk National University, Jeonju, Korea

<sup>2</sup>Department of Microbiology, Chungbuk National University, Cheongju, Korea

### **Background:**

*Rhodobacter sphaeroides* is a gram negative purple nonsulfur photosynthetic bacterium, facultative photoheterotrophic bacterium capable of growing phototrophically or chemotrophically as either a heterotroph or lithotroph in the presence or absence of O<sub>2</sub>, depending on the energy source. In addition, it owns capability to produce all kinds of amino acids, nucleic acid materials, vitamins, bio-active substances, polyphenol and polyhydroxybutyrate (PHB).

### **Objectives:**

In this study we focus on analyzing the properties of organic compounds and reduction of CO<sub>2</sub> in *R. sphaeroides* under various culturing conditions. Moreover, it is another goal of this study to confirm the effect on promoting growth of other microorganisms caused by the complement of *R. sphaeroides* extract in various culture conditions.

### **Methods:**

*R. sphaeroides* KCTC1434 were used in this study. More precisely, the analysis of growth promoting effect of the extract of *R. sphaeroides* was conducted under various culture conditions.

### **Conclusions:**

Our data indicated that addition of the *R. sphaerodes* extract into culture media accelerated the growth of microorganisms. Therefore, there was a strong evidence showing that the *R. sphaerodes* extract has multifunctional potential to increase the physiological activity of other organisms. It is, thus, determined as an enhanced material which is able to force to activate the growth promotion of other organisms.

**CLONING AND HETEROLOGOUS EXPRESSION OF ACID AND THERMOSTABLE B-GLUCOSIDASE IN PICHIA PASTORIS X-33 FROM THERMOASCUS AURANTIACUS RCKK**

K.K. Jain<sup>1</sup>, S. Kumar<sup>1</sup>, K.N. Bhardwaj<sup>2</sup>, R.C. Kuhad<sup>1</sup>

<sup>1</sup>Lignocellulose Biotechnology laboratory Department of Microbiology,  
University of Delhi South campus, NEW DELHI, India

<sup>2</sup>UCOST, Uttarakhand Council Of Science and Techbology, Dehradun, India

**Background**

Thermostable cellulases offer several advantages like higher rates of substrate hydrolysis, lowered risk of contamination and increased flexibility with respect to process design. The production of cellulases from a thermophilic fungus identified as *Thermoascus aurantiacus* RCKK (Acc. No. JN676149) has been attempted.

**Objectives**

In order to increase production level of cellulases and eventually economize the process, heterologous expression of these genes in *Pichia pastoris* was carried out.

**Methods**

$\beta$ -glucosidase gene from *T. aurantiacus* RCKK was cloned and overexpressed in *P. pastoris* X-33.

**Conclusions**

A 2.5 fold higher production of recombinant  $\beta$ -glucosidase was achieved at shake flask level in comparison to natively expressed enzyme. Expression of  $\beta$ -glucosidase of about 96kDa was confirmed by SDS PAGE, western blot and zymogram analysis. The purified recombinant  $\beta$ -glucosidase was found to be stable in wide range of pH (3.0-8.0), temperature (up to 50% activity after 3 h at 80°C) and tolerant to the presence of ionic liquid (1-ethyl-3-methylimidazolium acetate [C2mim][OAc]. These properties make the recombinant enzyme an important catalyst for carrying out an efficient hydrolysis of cellulose to sugars and enzymatic deinking of recycled paper pulp. This will eventually open up potential of this enzyme.

## **RAPID DEGRADATION OF LIGNOCELLULOSIC BIOMASS**

H. Bae<sup>1</sup>, D. Lee<sup>2</sup>

<sup>1</sup>*Bioenergy Science & Technology, Chonnam National University, Gwangju, Korea*

<sup>2</sup>*Bioenergy Research Center, Chonnam National University, Gwangju, Korea*

### **Background**

The main obstacle to lignocellulose bioconversion is the presence of lignin and crystalline cellulose in plant cell wall. However, major factors have not been definitely determined between lignin and crystalline cellulose in enzymatic lignocellulose recalcitrance. The correlative information promotes a deeper understanding of lignocellulose bioconversion characteristics.

### **Objectives**

Our aim is to determine the major rate-limiting factor in the hydrolysis of popping pre-treated rice straw (PPRS) by examining cellulase adsorption to lignin and cellulose, re-hydrolysis, and amorphogenesis.

### **Methods**

Lignin was prepared from PPRS by enzyme treatment until complete hydrolysis of carbohydrates and used to measure enzyme adsorption. Re-hydrolysis experiments were repeatedly performed with 15.75 or 31.50 FPU g<sup>-1</sup>-biomass cellulase for 1 or 3 hour until complete hydrolysis of 1 or 2% PPRS. Amorphogenesis of PPRS was carried out with 80% phosphoric acid on ice for 1 hour.

### **Conclusions**

Lignin isolated from PPRS adsorbed 20% of enzyme loading from 3.15-31.50 FPU g<sup>-1</sup>-biomass, adsorbing low levels of exoglucanases, endoglucanase and xylanase. Marked inhibition by cellulose structural effect was occurred during re-hydrolysis steps. Amorphogenesis of PPRS resulted in twofold higher cellulase adsorption and increased the yield of the first re-hydrolysis step from 13% to 46%. The total yield was increased to 84% in 3 h. These results provide strong evidence that cellulose structure, not lignin, has a major effect on the enzymatic hydrolysis of lignocellulose.

## **BIOLOGICAL RECYCLING OF POLY(L-LACTIDE) (PLA) BY MICROBIAL ENZYME**

A. Youngpreda<sup>1</sup>, C. Chuensangjun<sup>2</sup>, S. Sirisansaneeyakul<sup>2</sup>, S. Suksamran<sup>1</sup>,  
W. Upamai<sup>1</sup>, V. Kitpreechavanich<sup>1</sup>, S. Krajangsang<sup>1</sup>

<sup>1</sup>Science, Srinakharinwirot University, Bangkok, Thailand

<sup>2</sup>Science, Kasetsart University, Bangkok, Thailand

### **Background**

Poly(L-lactide) (PLA) is a biodegradable polymer. It is synthesized from lactic acid that is produced by microbes from agricultural products. It has much attention since it plays an important role to resolve the global warming problem. In general, PLA is polymerized commercially by chemical processes. However, these processes need severe conditions, i.e. high temperature, high solvent and catalyst loading. Recently, biological polymerization methods have been presented using lipases for the bio-catalytic reaction.

### **Objectives**

This work we aimed to apply the biological process for recycle of PLA.

### **Methods**

Using a protease produced by *Actinomadura keratinolytica* strain T16-1. 1 g/L PLA powder was incubated at 77 °C for 24 h using an enzyme concentration of 100 mg/L. As a result, 750 mg/L lactic acid was obtained and used as substrate for re-polymerization of PLA. This was done by using commercial lipase under 0.1 vvm nitrogen atmosphere at 60 °C for 6 h.

### **Conclusions**

**Oligomers with molecular weight of 450 (n=4) were obtained. This is the first report to demonstrate the recycling of PLA wastes biologically.**

**FEMS-1584**

**OPTIMIZATION OF EXTRACELLULAR LIPASES PRODUCED BY NEWLY ISOLATED BACILLUS SAFENSIS STRAIN PSR**

P. Pikunkwan<sup>1</sup>, O. Pringsulaka<sup>1</sup>, N. Suwannasai<sup>1</sup>, W. Lorliam<sup>1</sup>, V. Kitpreechavanich<sup>2</sup>, S. Krajangsung<sup>1</sup>

<sup>1</sup>Science, Srinakharinwirot University, Bangkok, Thailand

<sup>2</sup>Science, Kasetsart University, Bangkok, Thailand

**Background**

Lipases are an important enzyme for many biotechnological applications due to they are biocatalysts which have an activity at mild condition. Recently, bacterial lipase was very interesting because it can be used for re-polymerization of biodegradable plastics such as poly(L-lactide).

**Objectives**

The present work was aimed to screen lipase-producing bacteria from oil-contaminated soil in South of Thailand and study the optimization of medium composition for lipase-production.

**Methods**

Lipase-producing bacteria with 662 strains were isolated from 100 soil samples according to opaque zone formation on Tween 80 agar. Strain PSR exhibited the highest lipase activities in both agar plate and production medium. It was identified as *Bacillus safensis* strain PSR based on 16S rRNA gene sequencing. Moreover, the factors influencing lipase production were investigated in shake flask such as carbon and nitrogen sources, pH, temperature and incubation time. The maximum enzyme activity 63.86 U/ml was obtained by using 0.5% (w/v) rice bran oil and 0.12 % (w/v) yeast extract as carbon and nitrogen sources, respectively, at pH 6.85, 37°C and 60 hours cultivation.

**Conclusions**

The study provides a high bacterial lipase production which is a good candidate to apply for recycle of biodegradable plastic waste in the near future.

**FEMS-1590**

**RECONSTRUCTION OF A CORE METABOLIC NETWORK RELATED TO MEDIUM-CHAIN-LENGTH POLYHYDROXYALKANOATE PRODUCTION BY PSEUDOMONAS SP. LFM046 FROM CARBOHYDRATES.**

J. Cardinali-Rezende<sup>1</sup>, P.M. Raduan Alexandrino<sup>1</sup>, R.A. T. P. S. Nahat<sup>1</sup>,  
L. Ferreira da Silva<sup>1</sup>, M. Keico Taciro<sup>1</sup>, J.G. Cabrera Gomez<sup>1</sup>

<sup>1</sup>Microbiology, Institute of Biomedical Sciences, Sao Paulo, Brazil

**Background**

Medium-chain-length polyhydroxyalkanoate (PHA<sub>MCL</sub>) are biodegradable elastomeric polymers produced from renewable resources. *Pseudomonas* sp. LFM046 is a PHA<sub>MCL</sub> producer from carbohydrates sources, presenting a better performance than the most studied *Pseudomonas putida* KT2440.

**Objectives**

In this work, based on 16S rDNA sequences, *Pseudomonas* species phylogenetically close to *Pseudomonas* sp. LFM046 were identified and their sequenced genomes were searched for genes involved in carbohydrates catabolism and PHA biosynthesis, allowing reconstructed a core metabolic network. To confirm this network, the whole genomic DNA of *Pseudomonas* sp. LFM046 was sequenced.

**Methods**

For this, genomic DNA was extracted and fragmented using Covaris. Paired-end sequencing library was constructed using TruSeq DNA PCR-Free LT Sample Preparation Kit. The library quantification was performed using QUBIT, **Agilent Bioanalyzer** and real time PCR. The library was sequenced on an Illumina MiSeq sequencer.

**Conclusions**

*De novo* assembly generated 34 contigs using 3,032,982 reads, and the average size of 50% of the contigs (N50) was 640,128 bp, with the maximum size of 1,038,386 bp. The genome size was estimated at 5,970,318 bp. All genes involved in carbohydrate metabolism and PHA biosynthesis previously detected in other *Pseudomonas* species were also identified and annotated in the genome of *Pseudomonas* sp. LFM046 using RAST software. It includes genes from Entner-Doudoroff (ED) and pentose phosphate (PPP) pathways, tricarboxylic acid (TCA) and glyoxylic acid cycles (GAC), *de novo* fatty acids (FAB) and PHA biosynthesis. Thus, a core metabolic network of *Pseudomonas* sp. LFM046 was reconstructed and is going to be used to determine flux distribution based on exchange flux measurements.

## **GEN SPECIFIC QUANTIFICATION OF BACTERIAL CELLS IN ACTIVATED SLUDGE SYSTEMS**

J. Möller<sup>1</sup>, T. Gehrke<sup>1</sup>, L. Steuernagel<sup>1</sup>, M. Denecke<sup>1</sup>

<sup>1</sup>Urban Water- and Waste Management, University of Duisburg-Essen, Essen, Germany

### **Background**

Modern waste water treatment plants utilize activated sludge systems to reduce soluble compounds in waste water. The diversity of the biocenosis is primarily affected by the composition of the treated waste water. Especially the distribution of carbon and nitrogen leads to a characteristic diversity. Information about the specific abundance of essential microorganisms can be used to improve the plant operation and stability of the biological degradation.

### **Objectives**

While available quantitative methods like MPN (most probable number) and qPCR (quantitative polymerase chain reaction) are time consuming, this work led to the development of a rapid and quantitative variation of the fluorescence in situ hybridisation (qrFISH). The main objective was to design a method for a daily industrial application.

### **Methods**

Fluorescence in situ hybridisation was carried out according to Nielsen (2009). Fluorescence particles were added to the sludge samples and used as a reference for quantification. Thereby the unknown loss of biomass throughout the FISH process could be compensated.

## **Conclusions**

The current results showed a strong correlation between cell counts before and after the hybridisation process. Figures 1 shows the comparison of quantification results by fluorescence microscopy and conventional counting in a Thoma chamber. The experiments were conducted with enriched cultures of bacterial cells. The primary limitation of quantitative FISH was overcome, and the results were achieved in the targeted time frame of 8 hours.

**CHARACTERIZATION OF RECOMBINANT LACCASE (BPCOTA) FROM  
BACILLUS PUMILUS MK001 AND ITS POTENTIAL FOR PHENOLICS  
DEGRADATION**

S. Kumar<sup>1</sup>, S. Ran<sup>2</sup>, K.K. Jain<sup>1</sup>, M. Goel<sup>2</sup>, R.C. Kuhad<sup>2</sup>

<sup>1</sup>Lignocellulose Biotechnology Laboratory Department of Microbiology,  
University of Delhi South campus, NEW DELHI, India

<sup>2</sup>Department of Biophysics, University of Delhi South campus, NEW DELHI, India

**Background**

Bacterial laccases are very less explored despite their superior properties such as high thermostability and wide pH stability. In the present study, Putative laccase (CotA) from *Bacillus pumilus* MK001 has been cloned and expressed in *E. coli* BL21(DE3).

**Objectives**

Hyper-production of recombinant bacterial laccase was carried out to utilize its potential in bioconversion of phenolics.

**Methods**

BPCotA was expressed in *E. coli* BL21(DE3) and purified to homogeneity. Purified enzyme was characterized for its thermal and pH stability. The 3D model of BPCotA was constructed based on the crystal structure of *B. subtilis* CotA (PDB Id: 1GSK) by homology modelling (Modeller 9.11). Modeled structure was refined and validated for stereochemical quality using PROCHECK, ERRAT, Verify 3D and PROSA servers. *In silico* interaction between enzyme and phenolics was studied out to predict *in vitro* phenolics degradation ability of the recombinant enzyme.

**Conclusions**

The recombinant BPCotA was purified with ~82% recovery exhibiting ~230 IU/mg specific activity. The recombinant BPCotA retained more than 50 % of the original activity after incubating at 80°C and 90°C for 90 min and 30 min, respectively, and more than 80% of its activity in the wide pH range 5.0-9.0 for 240 h. Increase in temperature from 30-90°C resulted in significant changes in secondary structure as predicted by far UV thermal CD spectra. Docking analysis showed that both ferulic acid and vanillin bind in the vicinity of predictive active site of recombinant protein. Further, *in vitro* action of the enzyme on phenolics resulted in bioconversion of both ferulic acid and vanillin.

<sup>2</sup>*Consultant, Tsukuba Environmental Microorganism Institute, Ibaraki Tsukuba, Japan*

**Background**

Biodiesel fuel (BDF) waste contains large amounts of crude glycerol as a by-product, and its treatment is an environmental problem. In this study, it was attempted to produce bio-ethanol from crude glycerol. In previous study, we isolated *Klebsiella variicola* strain TB-83D that could produce ethanol from glycerol. This strain has high potential of ethanol production, and its production was 32 g/L by using yeast extract (YE) as a nutrient. However, YE is very expensive, so it is not suitable for an industrial use.

**Objectives**

The objective of this study is to decrease its culture cost. And we attempted to use methane fermentation digested slurry (MFDS). MFDS is residue of methane fermentation and its cost is very low.

**Methods**

The experiment was conducted by 1 L fermenter at 25°C and the culture pH was maintained at around 8.0 with 6 N NaOH. Basal medium consist of 50 g/L of glycerol and 600 g/L of MFDS is used for ethanol production by strain TB-83D.

**Conclusions**

The ethanol production was decreased to 17 g/L by replacing YE with sterilized MFDS. However, we think that this result seems to be a promising start to establish a low cost ethanol production from BDF waste. Next, we used non-sterilized MFDS to reduce sterilizing cost. Unfortunately, ethanol production was decreased but 1,3-propanediol and acetate production were observed. It may be caused by other bacteria survived in the MFDS. Now we are trying to optimize the culture condition that strain TB-83D is dominant when using non-sterilized MFDS.

**CAT8 GENE IS INVOLVED IN REGULATION OF XYLOSE ALCOHOLIC  
FERMENTATION IN THE THERMOTOLERANT YEAST HANSENULA  
POLYMORPHA**

J. Ruchala<sup>1</sup>, O. Kurylenko<sup>2</sup>, K. Dmytruk<sup>2</sup>, A. Sibirny<sup>1</sup>

<sup>1</sup>Department of Biotechnology and Microbiology, University of Rzeszow, Rzeszów,  
Poland

<sup>2</sup>National Academy of Science of Ukraine, Institute of Cell Biology, Lviv, Ukraine

**Background**

Efficient alcoholic fermentation of hexose and pentose sugars by yeast is essential to achieve maximal ethanol yield from lignocellulosic hydrolyzates. It is known that *CAT8* encodes carbon source-responsive transcriptional activator that controls expression of genes involved in gluconeogenesis. Deletion of *CAT8* in the non-conventional yeast *Pichia guilliermondii* activated alcoholic fermentation.

**Objectives**

The aim of this work was to isolate mutants of *H. polymorpha* with knock out of the gene *CAT8* and study their alcoholic fermentation. The strains were planned to be constructed in the backgrounds of the wild-type strain and of the mutant with elevated ethanol production from xylose due to overexpression of the genes encoded the key enzymes involved in xylose metabolism (xylose reductase, xylitol dehydrogenase, xylulokinase) and resistance to 3-bromopyruvic acid (glycolysis inhibitor).

**Methods**

The cassettes for *CAT8* gene deletion was constructed by used of homologous recombination method with gene *HphNT1* conferring resistance to hygromycin B as the selective marker. Fermentation was carried out at a temperature of 45°C with limited aeration. Concentrations of ethanol in the medium were determined using alcohol oxidase/peroxidase-based enzymatic kit 'Alcotest'.

**Conclusions**

Deletion of *CAT8* gene did not have effect on glucose alcoholic fermentation. At the same time, constructed knock out strains showed an improved xylose alcoholic fermentation relative to the parental strains. The  $\Delta cat8$  strains isolated from the best available ethanol producer accumulated up to 12.5 g of ethanol/L at 45°C after 3 day fermentation without correction for evaporation. This is the 30 fold increase as compared to the wild-type strain

**CHIMERIC ROTAVIRUS AND HEPATITIS A VIRUS-LIKE PARTICLES INDUCE VIRUS-SPECIFIC HUMORAL AND CELLULAR IMMUNE RESPONSES IN MICE**

Y. Kim<sup>1</sup>, S. Kim<sup>1</sup>, W. Kim<sup>1</sup>

<sup>1</sup>Medical microbiology, Chung-Ang University, Seoul, Korea

**Background**

Rotavirus and hepatitis A virus (HAV) are transmitted by the fecal-oral route and continues to be endemic throughout the world. Virus-like particles (VLPs) is safe and represents an economical approach to combined multivalent vaccine development.

**Objectives**

D2/VP7 VLPs demonstrated excellent combined vaccine candidate and may lead to the development of a commercialized vaccine worldwide for preventing both rotavirus and HAV.

**Methods**

In the current study, we evaluated the humoral and cellular immune responses in mice vaccinated with hepatitis A virus/rotavirus VLPs vaccine manufactured in methylotrophic yeast *Pichia pastoris* strain GS115. The VLPs were comprised of the hepatitis A virus D2 epitope and rotavirus  $\Delta$ VP7 proteins. BALB/c mice vaccinated with chimeric VLPs.

**Conclusions**

VLPs produced high levels of neutralizing antibodies in sera against rotavirus and HAV. Induction of the secretion cytokines were detected from anti sera. In addition, splenic CD4+ and CD8+ T cell accessory molecules increased and produced cytokines after vaccination.

<sup>2</sup>*Technology, UNESP, Jaboticabal, Brazil*

**Background**

Biopolymers are becoming more and more attractive for the industry due to their biological/natural origin, sustainability, biodegradability and low toxicity. This results in an increased demand for novel biopolymers, including exopolysaccharides (EPS) for different biotechnological purposes. It is worth to mention a broad spectrum for applications ranging from human health, over food and fodder production to chemical industry and environmental applications.

The ability to synthesize EPS is quite common among bacteria. Thus, as described exopolysaccharides differ in their physical and chemical properties, it may be surprising that only few of those products were successfully commercialized.

**Objectives**

In our studies we focused on *Acidobacteria*, highly divers and environmentally widespread but not well studied bacteria phylum, as a source of valuable compounds. The ability to synthesize EPS has been previously reported for some members of this phylum. However, its chemical composition and properties were not investigated up to date.

Taking into consideration a total lack of information on acidobacterial EPS, the aim of the present work was first of all to gain insight into the nature of those polymers and second to explore some of the characteristics potentially novel and superior for industrial applications.

**Methods**

We thus, focused on isolation, purification and physico-chemical characterization of EPS. Additionally, the stability of emulsions formed with selected oils and hydrocarbons.

**Conclusions**

The study proved different composition of EPS produced by closely related bacteria translating into differences in its properties but also a high stability of emulsions suggesting potential of EPS as stabilizing agents and/or bio-emulsifiers.

**DETERMINATION AND CHARACTERIZATION OF PHYTASE FROM A NEWLY ISOLATED BACILLUS SP.**

K. Erkan<sup>1</sup>, N. Aksöz<sup>1</sup>

<sup>1</sup>Biology, HACETTEPE UNIVERSITY, ANKARA, Turkey

**Background**

Phytate is the primary storage of phosphate in plants, and abundant in legumes, cereals and nuts. However, phytate make a polyanionic chelating agent which reacts with proteins, amino acids and divalent cations in humans and animals. Resulting in malnutrition and several health problems. Phytase is used as additive for degradation of antinutritional phytate and the enzyme is desired to be highly thermostable for it to withstand feed formulation conditions.

**Objectives**

The production of phytase is aimed from a new microbial source that was isolated from natural sources.

**Methods**

12 different soil samples taken from barn and coop surroundings were used for isolation of microorganism. To identify microorganism, we used 16srRNA analysis. For phytase production, strains were inoculated to Phytase-Screening Medium for 3d at 30°C. After phytase activity detection, enzyme was purified by ammonium-sulphate precipitation and DEAE-Sepharose. Samples were analyzed by SDS-PAGE.

**Conclusions**

Isolate (K12) was found *Bacillus subtilis* according to 16S rRNA sequencing. Several production parameters were optimized in order to ensure high enzyme production. In production medium, glucose was founded as the most suitable C-source and ammonium nitrate (NH<sub>4</sub>NO<sub>3</sub>) was found to be most suitable N-source. In the presence of glucose, NH<sub>4</sub>NO<sub>3</sub>, sodium phytate and stirred speed (150 rpm), 72 hours incubation at 30°C were the most suitable conditions for phytase production. Phytase obtained from optimized production conditions, at pH 6.5 at 60°C and enzyme substrate ratio of 1:9 has the highest activity. MgCl<sub>2</sub>, CuCl<sub>2</sub>, CoCl<sub>2</sub>, ZnCl<sub>2</sub> solutions and EDTA causing a loss of phytase activity whereas CaCl<sub>2</sub> solution has been found to be effective as an activity enhancer.

<sup>2</sup>The Key Laboratory of Molecular Microbiology and Technology Ministry of Education, Nankai University, Tianjin, China

**Background**

In recent years, the availability of explosive whole-genome information has thoroughly reshaped the strain reconstruction studies for potential industrial applications. Consequently, the concept of minimum genome factories (MGFs) was proposed, which can be defined as recombinant strains whose metabolism have been streamlined to the optimal minimal subset applicable to specific utilities. The construction of MGF generally involves multiple large-scale genomic manipulations leading to a highly reduced genome. To this end, a wide range of genome engineering systems have been developed and applied in various microorganisms. One new issue raised thereafter is the fitness assessment of numerous resulting genome-reduced cells.

**Objectives**

Establish a simple and efficient system to evaluate the genome-reduced *Saccharomyces cerevisiae* chassis as platform for the production of value-added secondary metabolites.

**Methods**

A set of *S. cerevisiae* cells harboring large-scale deletions of different chromosomal regions was obtained using the recently developed *mazF*-based scarless genome engineering system. On the other hand, the coding sequence of tyrosinase *PPO2* from *Agaricus bisporus* was amplified and cloned into yeast expression vector pLC12. The recombinant plasmid was transformed into all deletion cells by lithium acetate method. The product of *PPO2* can convert intracellular tyrosine into colored substance melanin, which can be measured through spectral.

**Conclusions**

The tyrosine formation of yeast deletant cells can be readily deduced from the formation of melanin and this will be helpful in strain optimization for biosynthesis of valuable chemical based on tyrosine.

**AMYLASES OF THE POLYEXTREMOPHILIC BLACK YEASTS AUREOBASIDIUM SPP. AND THEIR BIOTECHNOLOGICAL POTENTIAL**

M. Turk<sup>1</sup>, J. Zajc<sup>1</sup>, N. Gunde-Cimerman<sup>1</sup>, C. Gostinca<sup>2</sup>

<sup>1</sup>Department of Biology, University of Ljubljana Biotechnical Faculty, Ljubljana, Slovenia

<sup>2</sup>, National Institute of Biology, Ljubljana, Slovenia

**Background**

Four varieties of *Aureobasidium pullulans* (Dothideales, Ascomycota), a cosmopolitan melanised yeast-like fungus with good stress tolerance, were recently redefined as four separate species: *A. pullulans*, *A. subglaciale*, *A. melanogenum*, and *A. namibiae*. These species inhabit various environments, including those with temperature and pH extremes, high UV radiation and high salt concentrations – and are thus considered to be polyextremotolerant. *Aureobasidium* spp. are biotechnologically important organisms, mainly due to their production of the extracellular polysaccharide pullulan, antimycotic aureobasidin A, siderophores, and various extracellular enzymes. *Aureobasidium pullulans* is also used in agriculture as a biocontrol agent while *A. melanogenum* is implicated in human disease. The recent sequencing of the genomes of the four above listed *Aureobasidium* species opened new possibilities for numerous novel applications in biotechnology, medicine, pharmacy, food industry, biofuel production, and in other fields.

**Objectives**

The aim of the study was to develop a yeast strain with good amylolytic activity under normal and stressful (industrially relevant) conditions.

**Methods**

In this study, we have cloned all alpha-amylase and glucoamylase encoding genes from the *Aureobasidium* species, used in the genome sequencing, into *S. cerevisiae*. The amylolytic performance of the transformants at different temperatures, low water activity and other relevant conditions was then evaluated. The best amylases were expressed in an industrial *S. cerevisiae* strain.

**Conclusions**

Yeast strains with good amylolytic activity under the conditions of increased salt concentration, low water activity, low temperatures and other relevant conditions were developed.

## IMPROVING THE PRODUCTION OF HYDROPHOBIN HFBI FROM *TRICHODERMA REESEI* ON AN INNOVATIVE BIOFILM SOLID PACKING SYSTEM FERMENTOR

D. Riveros<sup>1</sup>, M. Khalesi<sup>1</sup>, S. Telek<sup>1</sup>, C. Michiels<sup>2</sup>, F. Delvigne<sup>3</sup>, G. Derdelinckx<sup>1</sup>

<sup>1</sup>Malt technology, KU Leuven, Leuven, Belgium

<sup>2</sup>Microbial and molecular systems, KU Leuven, Leuven, Belgium

<sup>3</sup>Unite de bioindustries, ULG Gembloux, Gembloux, Belgium

### Background

Hydrophobins are amphipatic proteins with high surface activity produced by ascomycetes and basidiomycetes. their interfacial properties make them very interesting to use them as emulsifiers and stabilizators for the food industry. However a major drawback is the low production of protein without the use of genetic techniques. Here we report the use of an innovative biofilm reactor which uses a metallic packing system as a substrate to grow on.

### Objectives

- Increase the production of hydrophobin HFBII from *Trichoderma reesei* using a biofilm reactor system

**B**

- Design of a reproducible, easy to scale up and relatively cheap method to increase the production of a fungal hydrophobin from *Trichoderma reesei*.

### Methods

- Fungal strain and culture medium: *Trichoderma reesei* MUCL 44908 were

inoculated in 20L of culture medium supplemented with glucose.

-Bioreactor set up: Along with the fermentation under biofilm system a submerged fermentation was also carried out in order to compare the increase in the production. In the case of the biofilm, the reactor was filled with a metal structured packing (Sulzer, Chemtech) where a peristaltic pump recirculated the medium evenly over the top of the packing system, this cycle was continued for the total time of the fermentation.

### **Conclusions**

- The protein production was 2.16 times higher that when submerged culture was used.
- The total weight of the fungal biomass was 33% higher that in submerged culture.
- The separation process between medium culture and fungal biomass was greatly enhanced, more than 99% of the biomass was attached to the biofilm

## **MICROBES AS TOOLS FOR MYCOTOXIN DEGRADATION**

B. Neumayer<sup>1</sup>, K. Naehrer<sup>2</sup>, P. Kovalsky<sup>2</sup>, G. Schatzmayr<sup>3</sup>

<sup>1</sup>*Microbiology, BIOMIN Research Center, Tulln, Austria*

<sup>2</sup>*R&D Management, BIOMIN Holding, Herzogenburg, Austria*

<sup>3</sup>*Research Director, BIOMIN Research Centre, Tulln, Austria*

### **Background**

Mycotoxins are secondary metabolites produced by several fungi. These toxic chemicals play a major role as feed and food contaminants. They can severely impact animal health, which is associated with high costs in livestock industry. Approximately 25% of all commodities worldwide are polluted by mycotoxins. The most prominent mycotoxins in contaminated food are Aflatoxins (hepatotoxic and cancerogenic), Deoxynivalenol (immunosuppression, protein synthesis inhibition), Zearalenone (infertility, abortion), Fumonisin (hepatotoxicity, nephrotoxicity) and Ochratoxin A (Neurotoxicity and cancerogenicity).

### **Objectives**

To counteract this problem, several strategies are applied, which involve prevention of fungal contamination during production and storage, followed by physical, chemical, and biological methods to reduce mycotoxin levels.

### **Methods**

Biological methods such as the use of microbial detoxifiers have the highest potential for feed decontamination. Bacteria capable of metabolizing mycotoxins allow decontamination and preserve nutritional value at the same time. To identify microbial detoxifiers, contaminated soil samples are cultured with a mycotoxin of interest to enrich, potential degrading strains. This eases the screening of single colonies for detoxification, which is a time consuming procedure and associated with extensive labor. Once the organism responsible for detoxification has been isolated and identified, further experiments are necessary to ensure the organism is fermentable, non-pathogenic and can be applied as direct feed additive.

### **Conclusions**

To date several detoxifying microbes have been found and characterized. An example for such a detoxifier is the strain BBSH 797 which degrades trichothecenes and is the only detoxifying feed additive on the market.

**Biotechnology and industrial microbiology**

**PENIOPHORA SP. CBMAI 1063 AS LACCASES PRODUCER: A MARINE ADAPTED STRAIN**

L.D. Sette<sup>1</sup>, P.H. Mainardi<sup>1</sup>, I.V.R. Otero<sup>1</sup>, H. Ferreira<sup>1</sup>

<sup>1</sup>Department of Biochemistry and Microbiology, Institute of Biosciences - UNESP, Rio Claro, Brazil

**Background**

Laccases are oxidoreductases enzymes that use molecular oxygen to oxidize phenolic and non-phenolic compounds. Laccases' applications are related to bioremediation of hazards compounds, biobleaching and mill water treatment on pulp/paper industry, as component for phenolic detection, and for the synthesis of new "eco-friendly" polymers, antibiotics and cosmetics. Although its importance, it is still lacking ways to produce high amounts of laccases. Therefore, the search of new laccases and new producers are highly important for its commercial application. The marine-derived basidiomycete *Peniophora* sp. CBMAI 1063, isolated from the sponge *Anphimedon viridis* (Brazillian coast) is able to produce significant amounts of laccase. Previous studies showed that the laccase produced by this fungus has a good pH/thermal activity range and metallic ions resistance.

**Objectives**

To evaluate the laccase production by *Peniophora* sp. CBMAI 1063 under the presence of CuSO<sub>4</sub> and saline conditions.

**Methods**

The fungus was cultivated in 50 mL of optimized medium under different concentrations of CuSO<sub>4</sub> and artificial seawater (ASW) during 7 days at 140 rpm and 28 °C. Laccase was quantified spectrophotometrically using ABTS as substrate.

**Conclusions**

The highest laccase activity (around 2000 U L<sup>-1</sup>), was obtained in the presence of 2 mM of CuSO<sub>4</sub> and 65% (v/v) of ASW. There was no laccase activity in the absence of ASW, suggesting its importance in fungal metabolic pathway. *Peniophora* sp. CBMAI 1063 has shown a great potential to be a laccase producer under saline conditions. The produced laccase are being characterized and its genes are being studied for heterologous expression.

**EFFECTS OF ENVIRONMENTAL CONDITIONS ON THE EXOPOLYSACCHARIDE PRODUCTION OF A NOVEL BACILLUS STRAIN ISOLATED FROM SOIL**

A. Avci<sup>1</sup>, E. Ergene<sup>2</sup>

<sup>1</sup>*Faculty of Engineering, Sakarya University, Sakarya, Turkey*

<sup>2</sup>*Faculty of Health Sciences, Istanbul Esenyurt University, Istanbul, Turkey*

**Background**

Microbial exopolysaccharides (EPS) have wide range of applications in food, pharmaceutical and other industries due to their stabilizing, gelling and texturizing properties. Various EPSs from different microorganisms including yeast and bacteria have been determined. They can be either homopolysaccharides (e.g. cellulose, dextran, pullulan, levan, curdlan) or heteropolysaccharides (e.g. xantan, gellan).

**Objectives**

In this study, exopolysaccharide production of a novel *Bacillus* strain ZBP4 on molasses was investigated. Effects of some environmental conditions on the production were also determined.

**Methods**

The bacterial growth was carried out in Nutrient Broth at 35 °C for 24 h. The medium for EPS production contained 60 g molasses, 5 g yeast extract, 5 g peptone, 1 g K<sub>2</sub>HPO<sub>4</sub>, and 0.1 g MgSO<sub>4</sub>·7H<sub>2</sub>O in one liter of distilled water. Effects of temperature (30 to 45 °C), pH (4.0- to 9.0), substrate concentration (10, 20, 30, 40, and 60 g/L molasses), nitrogen sources (ammonium sulfate, peptone, tryptone, and yeast extract), and aeration (80, 100, 150, and 200 rpm) on the EPS production were determined. For the isolation of EPS, cells were removed by centrifugation and supernatant was boiled and proteins were precipitated with trichloroacetic acid. Protein free supernatant was mixed with cold ethanol and centrifuged to precipitate EPS. Amount of EPS was determined with phenol-sulfuric acid method using glucose as standard.

**Conclusions**

The strain was produced highest amount of EPS at 60 g/L molasses concentration, 33 °C, pH 5.0. Tryptone was the best nitrogen source for EPS production. At 100 rpm agitation speed EPS production was the highest.

**ASSEMBLY AND GRAFTING OF PATHWAYS FOR SYNTHESIS OF BERRY HIGH-VALUE PHENOLICS IN LACTOCOCCUS LACTIS.**

A. Solopova<sup>1</sup>, P. Gaspar<sup>2</sup>, J. Förster<sup>2</sup>, O.P. Kuipers<sup>1</sup>

<sup>1</sup>Molecular Genetics, University of Groningen, Groningen, Netherlands

<sup>2</sup>DTU Biosustain, Danmarks Tekniske Universitet, Hørsholm, Denmark

**Background**

Plant phenolics demonstrate promising effects in the combat of cardiovascular disease, certain types of cancer, neurodegenerative diseases, allergies, diabetes and inflammation. Accordingly, the food industry actively searches for natural alternatives, such as anthocyanins, to replace synthetic dyes. The increasing consumers demand for plant-derived natural products with health-promoting (eg. nutraceuticals) and/or biotechnological applications (eg. food colorants) requires the implementation of innovative solutions to the large-scale production of such compounds. One such opportunity is offered by the exploitation of microbial hosts as cell factories.

**Objectives**

Our aim was to reconstruct the pathway for plant anthocyanin pelargonidin-O-glucoside production from flavanone naringenin in *Lactococcus lactis*.

**Methods**

In order to assemble a functional pathway, native genes from various plants and synthetic codon-optimized genes were cloned in *L. lactis*, and their expression was tested in this bacterium. Then, highly expressed genes were assembled in one anthocyanin production cluster in *L. lactis*.

**Conclusions**

In this study, we present the construction of an artificial gene cluster consisting of four native and codon-optimized plant genes for synthesis of anthocyanin pelargonidin-O-glucoside from naringenin in *L. lactis*.

## **INHIBITORY EFFECTS OF VARIOUS ENVIRONMENTAL CONDITIONS ON METHANOGENIC CONSORTIA**

M. Cieczkowska<sup>1</sup>, K. Poszytek<sup>1</sup>, K. Swiecka<sup>1</sup>, A. Skłodowska<sup>1</sup>, L. Drewniak<sup>1</sup>

<sup>1</sup>Laboratory of Environmental Pollution Analysis,

University of Warsaw Faculty of Biology, Warsaw, Poland

### **Background**

In our previous work three methanogenic consortia were selected from environments with high concentration of methane with biological origin: (i) anaerobic digester biogas plant (AD), raw sewage sludge waste (RSS), cattle slurry (CS). Those consortia are highly specialized in stable and effective biogas production during mesophilic anaerobic digestion from maize silage.

### **Objectives**

The aim of this study was verification of: (i) the ability to effective production of biogas from maize silage by the selected microbial consortia under various temperature and pH conditions, and (ii) the stability of microbial consortia community under various temperature and pH conditions.

### **Methods**

Lab-scale anaerobic digestion process. Biogas yield: daily biogas production, methane content were analyzed by gas chromatography GC-MS. Physical and chemical analysis: pH, volatile fatty acids (VFA), chemical oxygen demand (COD), ammonium, total solids (TS), volatile solids (VS). Determination of total cell counts by fluorescence microscope at a magnification of 600, using the filter set WU for DAPI detection. DNA isolation and purification. PCR amplification. Denaturing gradient gel electrophoresis (DGGE) of archaeal and bacterial 16S rRNA.

### **Conclusions**

The obtained results showed that the selected consortia are able to produce biogas in broad range of environmental conditions. However, the process is running with a lower methane yield in psychrophilic and acidogenic condition. These results also demonstrated that selected consortia have broad spectrum of activity and could be used as a “biostarter” in start-up trial operation in different biogas plant technology process.

Biotechnology and industrial microbiology

**COMPARATIVE EFFICIENCY OF ADDING ETHANOL OR POTASSIUM METABISULPHITE IN FUEL ALCOHOL FERMENTATIONS CONTAMINATED WITH DEKKERA BRUXELLENSIS: EFFECT ON THE CELL NUMBER AND ETHANOL YIELD**

S.R. CECCATO-ANTONINI<sup>1</sup>, A.P.G. Bassi<sup>1</sup>, A.L. Paraluppi<sup>1</sup>, V.R. Reis<sup>1</sup>

<sup>1</sup>Tecnologia Agroindustrial, Universidade Federal de São Carlos, ARARAS, Brazil

**Background**

Fuel alcoholic fermentations contaminated with *Dekkera bruxellensis* result in decreased ethanol yield.

**Objectives**

The aim of this work is to compare the efficiency of two cell treatments carried out prior to the fermentation to control the growth of *D.bruxellensis* without affecting the starter yeast *Saccharomyces cerevisiae* and the ethanol yield, in pure and mixed cultures.

**Methods**

The treatments consisted in the addition of 13% (v/v) ethanol or 250mg/l potassium metabisulphite (PMB) to the acidic solution (pH2.0), for 2 hours at 30°C, under shaking, in which the cells were introduced. After treatment, the cells were washed twice with sterile water, centrifuged and inoculated in sugar cane juice for 12 hours. The cell number was estimated by plating the samples in WLN medium with and without actidione to count the CFU number of *D.bruxellensis* and *S.cerevisiae*, respectively. Alcohol production was also determined.

**Conclusions**

In the mixed culture, the addition of ethanol to the acidic solution had similar effect over *S.cerevisiae* and *D.bruxellensis*, however the cell number increased after the fermentation time only for *S.cerevisiae*. The ethanol production was reduced by 6%. When PMB was used, the ethanol production was decreased considerably (74%) although the number of *S.cerevisiae* was not affected. *D.bruxellensis* was not affected at all. The interaction between PMB and *S.cerevisiae* to inactivate the toxic effect of this substance may be the reason why the fermentation yield was affected considerably. The addition of 13% ethanol in the cell treatment was the most efficient and the least harmful. Support: FAPESP

**LIGNINOLYTIC ENZYME ACTIVITIES AND CORN STRAW DELIGNIFICATION BY THE FUNGAL STRAIN CMU-196 OF PARACONIOTHYRIUM SP.**

M. Arredondo-Santoyo<sup>1</sup>, G. Vázquez-Marrufo<sup>1</sup>, M.S. Vázquez-Garcidueñas<sup>2</sup>

<sup>1</sup>*Centro Multidisciplinario de Estudios en Biotecnología Facultad de Medicina Veterinaria y Zootecnia, Universidad Michoacana de San Nicolás de Hidalgo, Tarímbaro, Mexico*

<sup>2</sup>*División de Estudios de Posgrado Facultad de Ciencias Médicas y Biológicas "Dr. Ignacio Chávez", Universidad Michoacana de San Nicolás de Hidalgo, Morelia, Mexico*

**Background**

Filamentous fungi degrade lignin by producing extracellular oxidative enzymes such as laccase (LAC), lignin peroxidase (LiP) and manganese peroxidase (MnP). These enzymes have diverse biotechnological applications, including straw delignification intended for biofuels production or ruminant feed. *Paraconiothyrium* is an ascomycete genus recently described whose species can produce ligninolytic enzymes; however, until now only few strains within the genus have been analyzed for this purpose.

**Objectives**

The aim of this work is to analyze the production of the extracellular LAC, LiP and MnP in the strain CMU-196 of *Paraconiothyrium* sp., and to evaluate the corn straw delignification by this strain.

**Methods**

Basal and induced enzyme activities were determined by incubating the strain CMU-196 in potato dextrose broth (PDB) at 24 °C and 128 rpm. Induced media were supplemented with ground corn straw (2% w/v), an aqueous extract of it (10% v/v) and CuSO<sub>4</sub> (150 µM). Corn straw delignification in a solid state fermentation was followed by scanning electron microscopy (SOM).

**Conclusions**

Maximum activity for MnP (83.72 U/ml) and LAC (103.64 U/ml) was shown at 5<sup>th</sup> day of incubation in PDB supplemented with ground corn straw. Maximum activity of LiP (25.66 U/ml) was observed at 6<sup>th</sup> day of incubation in basal medium. SOM images reveal an increase in delignification of vascular tissue of the corn straw inoculated with the fungus since week 4<sup>th</sup> until the end of treatment at week 12<sup>th</sup>. The strain CMU-196 produce high levels of the three extracellular ligninolytic enzymes and has potential for straw delignification.

**FEMS-2027**

**Biotechnology and industrial microbiology**

**GROWTH AND ETHANOL PRODUCTION OF DEKKERA BRUXELLENSIS AND SACCHAROMYCES CEREVISIAE STRAINS REGARDING THE TYPE AND CONCENTRATION OF THE CARBON SOURCE UNDER VARYING SHAKING CONDITIONS**

A.P.G. Bassi<sup>1</sup>, B.C.P. Sanches<sup>2</sup>, A.L. Paraluppi<sup>2</sup>, V.R. Reis<sup>1</sup>, S.R. Ceccato-Antonini<sup>2</sup>

<sup>1</sup>Ciência e Tecnologia de Alimentos, ESALQ - USP, Piracicaba, Brazil

<sup>2</sup>Dept Tecnologia Agroindustrial e Socio-Economia Rural,  
Centro de Ciências Agrárias Universidade Federal de São Carlos, Araras, Brazil

**Background**

The contamination of fuel alcohol fermentations with *Dekkera bruxellensis* brings about decrease in ethanol productivity and yield.

**Objectives**

Growth and fermentation profiles of two strains of *D.bruxellensis* and one strain of *S.cerevisiae* were evaluated under varying conditions of shaking in synthetic medium with glucose or sucrose as carbon source in different concentrations. We aimed to verify if the conditions to obtain higher alcohol production are similar for both yeast species.

**Methods**

Erlenmeyer flasks containing yeast cells in 200 ml of synthetic medium containing glucose or sucrose (50, 100 and 150g/l) were maintained at 30°C for 96 h under 0, 150 or 250 rpm. Growth was monitored by optical density at 600 nm and alcohol production was determined by density.

**Conclusions**

The strains of *D.bruxellensis* displayed similar results concerning growth: it was higher under shaking conditions regardless the carbon source type and concentration and was higher in sucrose than in glucose. The best conditions to achieve higher alcohol production were not similar and it was dependent on the shaking and the carbon source concentration. For *S.cerevisiae*, the growth was higher with shaking and no effect of the carbon source type and concentration was detected. Alcohol

production was substantially higher in static cultures regardless the carbon source. Sucrose at 150g/L, which is the basic fermentation medium in static cultures, favors alcohol production by *S.cerevisiae* but it does not for *D.bruxellensis*, whose growth is stimulated by sucrose. These results confirm the role of this yeast as contaminant and shows the variability exhibited among strains. Support: FAPESP

<sup>2</sup>*Institute of Molecular Enzyme Technology,  
Heinrich Heine University Düsseldorf & Forschungszentrum Jülich GmbH, Jülich,  
Germany*

<sup>3</sup>*Protagen AG, Otto-Hahn-Str. 15, Dortmund, Germany*

**Background**

Membrane proteins (MPs) play a crucial role in cell biology of any living organism. Nearly 30% of all open reading frames encode MPs and more than 50% of currently available pharmaceuticals target MPs. Despite their importance, the function of most MPs has not been assigned, yet.

**Objectives**

Since production of MPs is commonly limited by their hydrophobic nature, it is inevitable to generate novel expression systems that allow the high-level production of this class of enzymes. Here, we present an alternative expression system based on the bacterium *Rhodobacter capsulatus*, which is – due to its phototrophic nature – especially suited for the synthesis of MPs.

**Methods**

The facultative anaerobic purple bacterium *R. capsulatus* is able to grow either chemotrophically or phototrophically. Under latter conditions, it forms an intra-cytoplasmic membrane system (ICM) and vesicles, harboring the proteins of the host's photosystem and heterologously produced MPs. To characterize the expression properties of this system, several genes encoding monooxygenases, diagnostic-relevant MPs as well as GPCRs were cloned into a comprehensive set of novel broad host range expression plasmids of the pRho series. Subsequent accumulation, localization and activity studies were conducted to evaluate the alternative expression system.

**Conclusions**

With *R. capsulatus* and the pRho plasmids we have developed an alternative, powerful expression system for the synthesis of heterologous MPs. Our system is particularly suited for the production of monooxygenases, diagnostic-relevant proteins and GPCR-(like) proteins with yields of more than 10 mg per liter culture.

**INNOVATION IN THE CONJUGATION PROCESS OF THE CAPSULAR POLYSACCHARIDE PRODUCED BY HAEMOPHILUS INFLUENZAE TYPE B LINKED TO TETANUS TOXOID**

G.C. Barazzone<sup>1</sup>, P.H. Nakazone<sup>1</sup>, M. Takagi<sup>1</sup>, J. Cabrera-Crespo<sup>1</sup>, M.M. Tanizaki<sup>1</sup>

<sup>1</sup>*Centro de Biotecnologia, Instituto Butantan, São Paulo, Brazil*

**Background**

*Haemophilus influenzae* type b is a Gram-negative bacterium causing pneumonia and meningitis. Its capsular polysaccharide - PRP is the main virulence factor. Vaccines based on PRP conjugated to protein are very efficient. The low yield of the conjugate has motivated the development of conjugation process to attend the demand of low-income countries. DMT-MM (4-[4,6-dimethoxy-1,3,5-triazin-2-yl]-4-methylmorpholinium chloride) used as activation molecule is an alternative to improve the conjugation reaction and the anti-PRP IgG level was statistically similar to commercial vaccine.

**Objectives**

To improve the conjugation process to make feasible the production of conjugate vaccine in large scale (g).

**Methods**

PRP (2.3g at 10g/L) was oxidized by  $\text{NaIO}_4$ , quenched with glycerol and purified by tangential ultrafiltration resulting PRP-Oxi. PRP-Oxi (1.9g at 8g/L) was mixed with adipic acid dihydrazide (ADH) followed by addition of  $\text{NaBH}_3\text{CN}$ . After 4 hours,  $\text{NaBH}_4$  was added and submitted to ultrafiltration resulting PRP-AH. PRP-AH (15g/L) was reacted with TT (15g/L) in the presence of DMT-MM (0.1M) and the conjugate product was purified by size exclusion chromatography.

**Conclusions**

In large scale some adjustment were required in order to achieve the desired yield. For instance, glycerol amount was increased to stop the oxidation (83%). In the next step the amount of ADH was raised to avoid intermolecular reaction with 94% of PRP-AH. These yields are in agreement with those obtained in small scale (mg). The last step (mg scale) yielded 46% and now we are working on gram scale. Further studies considering immunological aspects will be performed.

## **GENOME SHUFFLING OF LACTOBACILLUS RHAMNOSUS FOR IMPROVED PRODUCTION OF LACTIC ACID**

S.B. Dahikar<sup>1</sup>

<sup>1</sup>Department of Microbiology,

Sanjivani Arts Commerce and Science College Kopargaon, Kopargaon, India

### **Background**

The development of bio-based production leads to an increasing demand for rapid engineering of multiple complex phenotypes into a single production host. The approach of genome shuffling is providing a powerful platform for improving multiple complex phenotypes in ill-characterized hosts.

### **Objectives**

The main objectives of this study were to improve acid tolerance and lactic acid production from *Lactobacillus rhamnosus* through genome shuffling.

### **Methods**

In the present study, the genome shuffling was used to improve the acid tolerance of while simultaneously enhancing lactic acid production. A total of 10 yoghurt samples were randomly collected in sterilized glass bottles from farmers directly and were processed immediately for isolation of the lactic acid bacteria. The isolated 5 strains of *Lactobacillus rhamnosus* treated for adaptation of Low pH. Adapted wild-type strain in pH 4.0 medium was then used as the parental, or starter, for genome shuffling. All the isolated *Lactobacillus rhamnosus* strains were mutagenized using nitrosoguanidine (NTG) while genome shuffling was carried out using standard method. From the results, it was observed that, the mutants showed a small increase, from 6.1 to 11.2 g/l, in production of l-lactic acid in comparison with the Wild type strain.

### **Conclusions**

In conclusion, genome shuffling successfully improved the tolerance of *L. rhamnosus* towards acid. The research here demonstrated that genome shuffling could greatly accelerate the improvement of important phenotypes of microorganisms by developing their ability to circumvent the extreme process condition.

<sup>2</sup>Department of Biochemical Engineering, University of Debrecen, Debrecen, Hungary

<sup>3</sup>Institute of Chemical Engineering, Vienna University of Technology, Vienna, Austria

### **Background**

Filamentous fungi in general and *Aspergilli* in particular are amongst the most important cell factories in biotechnology, as they have an intrinsic potential to produce a variety of organic acids such as citrate, gluconate and itaconate in high quantities. In order to obtain high yields of citric acid by *A. niger*, the elimination of Mn (II) ions from the medium is a prerequisite. Mycelia grown under manganese deficiency form dense and very small pellets. In this study, *A. terreus* NRRL 1960, an itaconic acid producer strain was used to study the effects of external manganese (II) ion concentration on fungal morphology.

### **Objectives**

Our primary objective was to monitor time-course changes in the morphology of *A. terreus*, grown under different external Mn<sup>2+</sup> ion concentrations.

### **Methods**

Well-controlled, strongly aerated lab-scale batch fermentations were performed. Changes in fungal morphology was monitored by image analysis. External Mn (II) ion concentrations were determined by ICP-MS.

### **Conclusions**

The overwhelmingly mycelial morphology of *A. terreus* NRRL 1960 progressively turned to pellet-like below 50 µg L<sup>-1</sup> Mn<sup>2+</sup> ion concentration. At 5 µg L<sup>-1</sup> Mn<sup>2+</sup> ion concentration and below, morphology was completely dominated by yeast-like, swollen cells.

**ANTIBIOTIC RESISTANCE AND VIRULENCE PROFILE OF BACILLUS PUMILUS GROUP MEMBERS**

R. Branquinho<sup>1</sup>, J. Pires<sup>1</sup>, M.M. Amorim<sup>2</sup>, M. Pintado<sup>2</sup>, L. Peixe<sup>1</sup>

<sup>1</sup>Ciências Biológicas - Laboratório de Microbiologia,

UCIBIO/REQUIMTE - Faculdade de Farmácia Universidade do Porto, Porto, Portugal

<sup>2</sup>CBQF – Centro de Biotecnologia e Química Fina, ESB-

UCP – Escola Superior de Biotecnologia Universidade Católica Portuguesa, Porto, Portugal

**Background**

*Bacillus pumilus* present a biotechnological and pharmaceutical relevance highlighted by their ability to produce compounds with different biological activities. Moreover, they can be also found as troublesome contaminants in industrial settings and also be associated with food poisoning. Recently, phylogenetic analysis supported on different biomarkers determined the reassignment of most *B. pumilus* as *Bacillus safensis* or *Bacillus invictae*. The absence of a resistance profile to antibiotics of human and veterinary importance and also of toxin encoding genes are pre-requisites specified by EFSA when their use is intended in the food sector.

**Objectives**

To evaluate the antibiotic susceptibility, and the presence of antimicrobial resistance or entero- and emetic-toxins encoding genes in a clonally diverse *B. pumilus* group collection.

**Methods**

Minimum inhibitory concentrations to different antibiotics were determined and interpreted according to clinical breakpoints and microbiological cut-offs, in a collection comprising *B. safensis* (n=27), *B. invictae* (n=9) and *B. pumilus* (n=4). Additionally, acquired genes encoding resistance to relevant human and veterinary antibiotics (tetracyclines, macrolides, aminoglycosides, glycopeptides, phenicols and oxazolidinones) and also entero- and emetic-toxins (cytotoxin K, haemolysin, non-hemolytic and emetic toxins) were screened by PCR.

**Conclusions**

Susceptibility to all antibiotics included in interpretative criteria for their testing on *Bacillus* spp. was observed. Nevertheless, high MIC values (8-64 mg/mL) were observed for cefotaxime, a therapeutically relevant antibiotic. All *B. pumilus* group species revealed the absence of acquired antibiotic resistance and virulence genes, suggesting that there is no recognized risk of their application in the food sector or in other relevant biotechnological uses.

<sup>4</sup>Helmholtz Institute for Pharmaceutical Research Saarland, Helmholtz Centre for Infection Research and Pharmaceutical Biotechnology at Saarland University, Saarbrücken, Germany

<sup>5</sup>Biocatalysis and Fine Chemicals Research, BASF SE, Ludwigshafen, Germany

#### Background

Microorganisms represent prolific sources for biotechnological relevant compounds which often need to be produced in heterologous hosts like *Escherichia coli*. Here, we present the Gram-negative bacterium *Burkholderia glumae* PG1 as a promising alternative production strain.

#### Objectives

*B. glumae* PG1 is known to secrete the lipase LipA which is used by the BASF SE for the production of enantiopure building blocks. A detailed genome comparison of *B. glumae* PG1 [1] with other representatives of this genus revealed that this phytopathogenic strain lacks the gene cluster encoding the biosynthesis of the important virulence factor toxoflavin.

#### Methods

Furthermore, we identified 25 clusters including PKS and NRPS for the production of secondary metabolites as well as genes encoding rhamnolipid biosynthesis enzymes resulting in the production of 20 mg/L rhamnolipids under non-optimized conditions.

We analyzed the genome of the industrial lipase production strain *B. glumae* LU8093 which was generated by random mutagenesis and identified 72 single nucleotide polymorphisms compared to the wild-type. Two of them were associated with the *lipAB* operon and affect its transcription as well as the efficiency of lipase secretion.

#### Conclusions

The identification of the putative SGNH hydrolase LipG and the construction and functional analysis of a T7 polymerase based expression strain further underline the biotechnological potential of *B. glumae* PG1.

**Background**

In this study, firstly, the ability of plant growth hormones (PGH) production capacity of more than a hundred Basidiomycetes isolates was screened.

**Objectives**

Plant growth regulators are commonly used by agricultural manufacturers in world wide. In our study, we have tried producing some of these plant growth regulators from a macro fungi, *Inonotus hispidus*.

**Methods**

*Inonotus hispidus* was firstly recorded as a PGH producer species and was selected for following experiments based on its 1033.65, 125.11, and 10.91 mg/L gibberellic acid (GA3), abscisic acid (ABA) and indole acetic acid (IAA) production values, respectively. Secondly, PGH producing capacity of *Inonotus hispidus* isolate was determined while the growth of the mushroom on different culture types (static, submerged and solid state). On 15th day of submerged fermentation, maximum plant growth hormones production was determined as 2478.85, 273.26, and 30.67 mg/L for GA3, ABA and IAA, respectively. Then, Plackett-Burman and response surface experimental designs were used for optimization of PGH production by *Inonotus hispidus*. Finally, the determined optimum conditions were investigated in stirred tank reactor scale to produce PGH in higher volume and reached results were, GA; 5441.54, ABA; 390.39 and IAA; 44.79 mg/L. PGH production by free and immobilized cells was also compared.

**Conclusions**

Consequently, production amounts of GA3, ABA and IAA by *Inonotus hispidus* in reactor scale were increased respectively 5.26, 3.12 and 4.1 fold according to screening step. The kinetic parameters of PGH production and growth of *Inonotus hispidus* ( $\mu$ ,  $r_s$ ,  $Q_s$ ,  $r_p$ ,  $Q_p$ ,  $Y_{p/s}$ ,  $Y_{p/x}$ ) were also determined in optimize and non-optimize conditions in Erlenmeyer flask and stirred tank reactor scales.

<sup>1</sup>Molecular Biology Laboratory,

State Research Center for Applied Microbiology & Biotechnology, Obolensk, Russia

### **Background**

Anthrax is major biosecurity threat. Apart from natural outbreaks, lethality of anthrax and recalcitrance of *B. anthracis* spores to environmental factors and disinfectants made it the most feared bioterrorist weapon.

Anthrax lethal toxin (LeTx) consisting of receptor-binding (protective antigen), and protease (lethal factor) subunits is main target for development of anthrax diagnostic and therapeutic tools. Aptamers represent important platform for discovery of target-specific affinity reagents. Particularly, aptamers known to be the source of efficient allosteric protease inhibitors [1]. Immuno-aptameric PCR possesses the highest known detection sensitivity [2].

### **Objectives**

The purpose of the present study was to develop new technique aimed at rapid isolation of high-affinity aptamers suitable as diagnostic and therapeutic candidates against LeTx.

### **Methods**

In the aptamer library screening, key elements to isolate high-affinity binders are: prevention of carryover of target-specific aptamers by nonspecific oligonucleotides, and early elimination of unbound and weakly bound species. Using LeTx as the target, we developed efficient, cost and time saving protocol of enabling isolation of high-affinity aptamers by using on-rate selection, tandem affinity purification of target-specific aptamers by double proteolytic elution that leaves tightest bound aptamers associated with the eluted target, whereas the majority of binders with intermediate affinity already dissociated and removed during the competitor-based off-rate selection.

### **Conclusions**

New aptamer selection technique is useful in isolation of ultra-high affinity aptamers targeting bacterial toxins.

The work was supported by Russian scientific fund research grant № 14-15-00630.

**SELECTION OF NANNOCHLOROPSIS OCEANICA CELLS WITH HIGHER INTRACELLULAR LIPIDS CONTENT BY FLUORESCENCE ACTIVATED CELL SORTING.**

*H. Osorio<sup>1</sup>, P. Von Dassow<sup>1</sup>, C. Jara<sup>1</sup>, M. Vásquez<sup>1</sup>*

*<sup>1</sup>Molecular Genetics and Microbiology, Pontificia Universidad Católica de Chile, Santiago, Chile*

**Background**

Microalgae are now the focus of interest due to their ability to produce a intracellular lipid feedstock that is suited to conversion in biodiesel. *Nannochloropsis oceanica* (N.O.) is a unicellular green alga intensely investigated because of the natural ability to form intracellular lipid bodies that contain triacylglycerol.

As a way to select the cells with spontaneous higher amount of intracellular lipids were separated those cells from a heterologous population using the technique of fluorescence activated cell sorting (FACS).

**Objectives**

Visualization of intracellular lipid droplets of N.O. by epifluorescence microscopy.

Visualization and selection of cells with high intracellular lipids content from heterologous populations of N.O. cultures by FACS.

Quantification of total lipids in selected cellular populations of N.O. under different culture conditions

**Methods**

The microalgal cultures were suspended in DMSO and stained with Bodipy 505/515. Flow Cytometer (BD Influx™ cell sorter) was used to detect the fluorescence signal of Bodipy. Neutral lipids stained showed a particular emission peak at 530 nm.

Total lipid fatty acid profiles were determined by GC of methyl esters.

**Conclusions**

Intracellular lipid droplets stained with Bodipy 505/515 was easily visualized by epifluorescence microscopy in N.O. cells.

The FACS technique allowed the visualization and separation of cellular populations enriched in intracellular lipids from liquid cultures of N.O.

Analysis of lipids quantification confirmed the obtaining of cellular populations with higher amounts of total lipids and fatty acids reaching 46% of total lipids by mg of dry weight.

<sup>3</sup>Department of Chemical Exact Scienc Institute Federal University of Amazon UFAM, UFAM, Manaus, Brazil

<sup>4</sup>Faculty of Agrarian Sciences of Federal University of Amazon, FCA, Manaus, Brazil

**Background:**

Endophyte fungi are usually find in Amazon Rainforest with high biodiversity, and biological and chemical potential. They can be found as endophytes, phytopathogens or saprophytes. *Candida* is a fungal pathogen responsible for opportunist infections in humans.

**Objectives:**

To produce exo- and endo-polysaccharide extracts from *Pestalotiopsis* sp. and *Talaromyces* sp., and assay them against *Candida albicans*.

**Material and Methods:**

Two fungi from the GEMMA group fungal collection were cultivated for 18 days on PDY medium.. Then the mycelium was separated from the medium. After add to culture medium from each fungus 1L of methanol, the mixture was left for 48 hours at 4 °C. The precipitate formed was separated by centrifugation and the solvent in the supernatant was evaporated in rotary evaporator. The aqueous phase was subjected to liquid-liquid extraction with ethyl acetate and the acetate extract was concentrated by rotary concentration.

**Conclusions:**

Three samples were selected for candidicidal assays: (1) *Talaromyce* inorganic partitioned, (2) *Pestalotiopsis* mycelium, and (3) *Talaromyce* culture aqueous. All extracts had revealed candidicidal activity and were subsequently tested at the concentrations of 1000, 750, 500 and 250 µg.mL<sup>-1</sup> to determine the minimum inhibitory concentrations. The sample (1) and (3) showed no satisfactory inhibition while (2) showed inhibition at 500 µg/ml.

**EXPRESSION, PURIFICATION AND CHARACTERIZATION OF A BIFUNCTIONAL 99-KDA PEPTIDOGLYCAN HYDROLASE FROM *PEDIOCOCCUS ACIDILACTICI* ATCC 8042**

I. García-Cano<sup>1</sup>, A. Farrés<sup>1</sup>

<sup>1</sup>*Alimentos y Biotecnología, UNAM Facultad de Química, Mexico City, Mexico*

**Background**

Lactic acid bacteria inhibit the growth of pathogens and food deleterious microorganisms because they produce substances with antibacterial activity, such as peptidoglycan hydrolases (PGH). *Pediococcus acidilactici* ATCC 8042 has been reported to inhibit pathogenic microorganisms such as *Staphylococcus aureus* through the production of two proteins with lytic activity, which are approximately 110 and 99 kDa. The 99-kDa PGH has high homology to a putative protein reported in *Pediococcus acidilactici* 7\_4, where two different lytics domains have been identified but not characterized.

**Objectives**

The aims of this work were cloning, expression, purification and biochemical characterization this bifunctional enzyme.

**Methods**

The 99-kDa PGH was cloned and expressed successfully and showed activity against *Micrococcus lysodeikticus*. The protein was then purified using gel filtration chromatography. For the characterization 4-Nitrophenyl-*N*-acetyl- $\beta$ -D-glucosamine was used as substrate.

**Conclusions**

The pure protein showed an optimal pH for antibacterial activity and stability of 6.0 and 5.0 to 7.0, respectively. The optimal temperature for activity was 60°C, and it lost all activity after incubation at 70°C for 1 h. The number of strains susceptible to the recombinant 99-kDa enzyme was lower to those lysed by the mixture of the 110- and 99-kDa PGHs of *P. acidilactici*, which indicates that there might be synergy and interactions between these two enzymes. This is the first peptidoglycan hydrolase from LAB that has been shown to possess two lytic sites. The results of this study will aid in the design of new antibacterial agents from natural origins that can combat foodborne disease and improve hygienic practices in industrial sector.

## **BIOCHEMICAL CHARACTERIZATION OF A SPORE LACCASE FROM A HALOTOLERANT BACTERIUM, BACILLUS SP.**

M. Amoozegar<sup>1</sup>, M. Siroosi<sup>1</sup>, K. Khajeh<sup>2</sup>

<sup>1</sup>Biology, University of Tehran Tehran Iran, Tehran, Iran

<sup>2</sup>Biochemistry, Tarbiat Modares University Tehran Iran, Tehran, Iran

### **Background**

Laccases, one of polyphenol oxidases, have many applications in different industries and can be used in bioremediation, organic synthesis, and biosensors.

### **Objectives**

In present study, different bacterial strains were screened to find laccase producing strain. Biochemical characterization and Crystal violet decolorization effect of the spore laccase from a spore producing strain was examined.

### **Methods**

As total 50 bacterial strains isolated from a soil sample of a chromite mine in Iran were screened for laccase production on nutrient agar medium supplemented with 3% (w/v) NaCl and 0.02% (v/v) guaiacol. Spores from a spore forming Gram-positive strain showed laccase activity. The strain was identified and pH and temperature optima for the enzyme activity were determined. Effects of inhibitors and metal ions on the enzyme activity were studied. Decolorization of Crystal violet was investigated by spore laccase.

### **Conclusions**

The closest relative of the laccase producing strain was *Bacillus safensis* FO-036b<sup>(T)</sup>. The spore laccase showed optimal activity at pH 5 and 35°C, had a good tolerance to metal ions, and retained 104% of its initial activity against 1 mM of NaN<sub>3</sub>. The enzyme decolorized 64% of 10 mg/L Crystal violet, so it could be a good candidate to bioremediation applications.

### **TO LOW COST FERMENTATION PROCESSES**

*R. Weusthuis<sup>1</sup>, D. Martens<sup>1</sup>, A. Mars<sup>2</sup>, R. Wijffels<sup>1</sup>, G. Eggink<sup>1</sup>, J. Sanders<sup>2</sup>*

*<sup>1</sup>Bioprocess Engineering, Wageningen University, Wageningen, Netherlands*

*<sup>2</sup>Food & Biobased Products, Wageningen University & Research Centre, Wageningen, Netherlands*

### **Background**

Fermentation processes have been used for over 45 centuries, especially for the production of food, with ethanol and lactic acid as the main biogenic compound. These products have a high added value, because they are used as stimulant and/or because of their food preserving nature. This high added value allows significant costs for the fermentation process.

During the last 30 years fermentation technology has also been applied for the production of chemicals and fuels. These products have to compete with low-cost petrochemicals, putting restrictions on the costs of the fermentation processes. The current state-of-art fermentation technology is often too expensive for competitive production of chemicals and fuels.

In the same period the instruments to modify microorganisms have evolved considerably. The ability to build whole genomes, the application of –omic techniques and genome scale modelling give unprecedented possibilities to design microorganisms for optimal product formation.

### **Objectives**

Instead of adapting the process to the microorganisms to reach the best results, it is now time to develop strategies which adapt the microorganisms to the process.

### **Methods**

Key drivers for process improvement are the reduction of oxygen requirement by redox engineering, the increase of product tolerance and the separation of the product from the aqueous broth by phase separation.

### **Conclusions**

In this paper/presentation we describe our activities to realize this and estimate the cost reduction that can be realized. Itaconic acid and fatty acids will be shown as examples. A cost reduction to a value below that of contemporary ethanol production (800 €/kg) seems feasible.

**Biotechnology and industrial microbiology**

## **REACTIVE OXYGEN SPECIES REGULATE LOVASTATIN BIOSYNTHESIS IN *ASPERGILLUS TERREUS***

J. Barrios-Gonzalez<sup>1</sup>, L.E. Gómez-Quiroz<sup>2</sup>, R.U. Miranda-Labra<sup>2</sup>

<sup>1</sup>*Biotecnología, Universidad Autónoma Metropolitana, Mexico D.F., Mexico*

<sup>2</sup>*Ciencias de la Salud, Universidad Autónoma Metropolitana, Mexico D.F., Mexico*

### **Background**

Lovastatin (LOV) is a secondary metabolite, produced by *Aspergillus terreus*. It has great commercial importance since it lowers cholesterol levels in blood. Studies from our group, showed a link between reactive oxygen species (ROS) and LOV biosynthesis in submerged (SmF) and solid-state fermentation (SSF). Our results showed that *sod1* gene (oxidative stress defense enzyme) was intensely expressed during rapid growth phase (or trophophase) in LOV fermentations, but it was down regulated in production phase or idiophase. Probably because of this, in that moment ROS levels increased, generating an oxidative state during idiophase (Miranda et al 2013).

### **Objectives**

The objective of the present work was finding evidence that ROS contribute to the regulation of lovastatin biosynthesis.

### **Methods**

ROS were manipulated during LOV fermentations. Exogenous antioxidants were used to eliminate or reduce ROS accumulation during lovastatin fermentations. Its effect on lovastatin production was determined. Also, its effect on the expression of LOV genes (*lovE* and *lovF*), and on genes *yap1* and *srrA* (encoding oxidative stress defense transcription factors) was determined by Northern analysis.

Similar (complementary) experiments, increasing ROS by H<sub>2</sub>O<sub>2</sub> addition to LOV fermentations, were also performed.

### **Conclusions**

1. ROS accumulation in idiophase is not only necessary for the normal production of lovastatin, but contributes to the transcriptional regulation of the biosynthetic genes, including the specific regulatory gene *lovE*.

2. ROS regulation could be mediated by oxidative-stress-response transcription factors: Yap1 might be acting as a negative regulator; while SrrA could play an important role in positively controlling lovastatin production.

**IDENTIFICATION AND BIOACTIVE POTENTIAL OF ENDOPHYTIC FUNGI  
ISOLATED FROM MEDICINAL PLANT WITHANIA SOMNIFERA**

V. Verma<sup>1</sup>, S. Rasool<sup>1</sup>

<sup>1</sup>*School of Biotechnology, Shri Mata Vaishno Devi University, Jammu, India*

**Background**

Endophytes are microbes that colonize living, internal tissues of plant without causing any immediate or negative effect. Various studies have shown that endophytes are endowed with great potential for human welfare like having potential in the form of antibiotics, antiviral, anti asthmatic, antioxidant and anticancer compounds. Endophytes from medicinal plants have become a hot topic for metabolite discovery. There is still a lot of potential of endophytes which need to be discovered for pharmaceutical applications. Keeping these things in consideration, the aim of the present study was to isolate fungal endophytes from different accessions of medicinal plant *Withania somnifera* and to screen the endophytes for the production of various bioactive molecules.

**Objectives**

To isolate the endophytic microorganisms from *Withania somnifera* (Ashwagandha) & screen for antimicrobial activity against a wide range of pathogenic microorganisms

**Methods**

Isolation of endophytes using the standard methodology published earlier

**Conclusions**

Out of 7 endophytes, four isolates were identified by ITS amplification and sequencing. All the four isolates showed significant similarity with *Alternaria alternata*, *Alternaria tenuissima* strain, *Alternaria* sp. and *Alternaria compacta*.

The isolated endophytes were also screened for antimicrobial activity against a wide range of pathogenic microorganisms and after analyzing the results some of the endophytes showed promising antimicrobial activities.

Our results confirm that the isolated endophytes could serve as an alternative source of various bioactive molecules of novel structure and function as endophytes are still largely unexplored.

**SECRETION AND FUNCTIONAL DISPLAY OF FUSION PROTEINS THROUGH THE CURLI BIOGENESIS PATHWAY**

N. Van Gerven<sup>1</sup>, I. Van den Broeck<sup>1</sup>, H. Remaut<sup>1</sup>

<sup>1</sup>*Structural and Molecular microbiology, Vrije Universiteit Brussel, Brussels, Belgium*

**Background**

Curli are functional amyloids expressed as fibres on the surface of Enterobacteriaceae. Contrary to the protein misfolding events associated with pathogenic amyloidosis, curli are the result of a dedicated biosynthetic pathway. A specialized transporter in the outer membrane, CsgG, operates in conjunction with the two accessory proteins CsgE and CsgF to secrete curlin subunits to the extracellular surface, where they nucleate into cross-beta strand fibres.

**Objectives**

Here we investigate the substrate tolerance of the CsgG transporter and the capability of heterologous sequences to be built into curli fibres.

**Methods**

We genetically fused different proteins to the C-terminus of csgA.

**Conclusions**

Non-native polypeptides ranging up to at least 260 residues were exported when fused to the curli subunit CsgA. Secretion efficiency depended on the folding properties of the passenger sequences, with substrates exceeding an approximately 2 nm transverse diameter blocking passage through the transport channel. Secretion of smaller passengers was compatible with prior DsbA-mediated disulphide bridge formation in the fusion partner, indicating that CsgG is capable of translocating non-linear polypeptide stretches. Using fusions we further demonstrate the exported or secreted heterologous passenger proteins can attain their native, active fold, establishing curli biogenesis pathway as a platform for the secretion and surface display of small heterologous proteins.

**STUDY OF THE BIOTECHNOLOGICAL POTENTIAL OF EXTREMOPHILE ACTINOMYCETES FOR THE BIOCONTROL OF FUNGAL DISEASES OF CEREAL CROPS UNDER VARIOUS ENVIRONMENTAL CONDITIONS**

L. Trenozhnikova<sup>1</sup>, A. Sadanov<sup>1</sup>, S. Aitkeldieva<sup>1</sup>, A. Balgimbaeva<sup>1</sup>, G. Ultanbekova<sup>1</sup>

<sup>1</sup>Committee of Sciences Ministry of Education and Sciences Republic of Kazakhstan, Institute of Microbiology and Virology, Almaty, Kazakhstan

**Background**

In the recent years, the applicability of actinomycete strains as probiotics for plants, serving as agents of biological control of plant diseases, has been actively investigated.

**Objectives**

415 strains of extremophile actinomycete strains from the unusual ecosystems of Kazakhstan.

**Methods**

Antifungal properties of extremophilic actinomycetes were studied against the fungal pathogens of grain cultures (genera *Fusarium* and *Aspergillus*) by agar diffusion method.

**Conclusions**

104 actinomycetes strains from the extreme ecosystems of Kazakhstan (solonchak, takirs and takir-type soils, solonetz and solod) showed antifungal activity against the fungal pathogens of grain cultures (*Fusarium sp.*, *Aspergillus niger*). 20 strains of extremophilic actinomycetes have been selected, capable of growing at a low content of nutrients in the medium, in the presence of high salt concentrations ( $\geq 5\%$ ) and pH level ( $\geq 9.0$ ). They have the ability to inhibit the growth of phytopathogenic fungi (diameter of inhibition zone 20-30 mm) in the different environmental conditions - neutral, in the presence of high NaCl concentrations (5% or more), and high pH values (9-11). This practically valuable feature is especially important for the plant cultivation since many biopreparations developed for neutral ecological niches become useless after salinization or alkalization of the soil. Scientific novelty of the research results lies in the use of biotechnological potential of extremophilic actinomycetes in the development of biological preparations for plant cultivation under various environmental conditions.

## **THERMOPHILIC FUNGI FOR EFFICIENT PLANT BIOMASS DEGRADATION**

J. van den Brink<sup>1</sup>, S. van der Horst<sup>1</sup>, M. de Vries<sup>1</sup>, B. Stielow<sup>1</sup>, R.P. de Vries<sup>1</sup>

<sup>1</sup>*Fungal Physiology, CBS-KNAW Fungal Biodiversity Centre, Utrecht, Netherlands*

### **Background**

A major challenge in the sustainable production of biofuels and biochemicals is efficient enzymatic conversion of plant biomass into monomeric sugars. Most enzyme mixtures are currently produced by a small selection of fungal species (e.g. *Trichoderma reesei*, *Aspergillus niger*). However, the fungal kingdom holds many more fungal species which produce enzyme mixtures with beneficial characteristics such as high (hemi-)cellulase activity and high thermostability. *Sordariales* is one of the few fungal orders with thermophilic isolates, of which many have been associated with the production of thermostable enzymes.

### **Objectives**

The aim of our study is to assess the diversity within *Sordariales* for efficient plant biomass degradation.

### **Methods**

Phylogenetic analysis and growth analysis revealed that optimal growth temperature is a polyphyletic trait within *Sordariales* with separate mesophilic, thermotolerant and thermophilic clades. Four thermophilic clades were clearly distinguished: *Myceliophthora* species, *Thielavia terrestris*, *Chaetomium thermophilum*, and *Mycothermus thermophilus*. Thermophiles within *Myceliophthora* showed the most potential as efficient plant biomass degraders. Especially *M. heterothallica* had good growth on a large range of substrate and was able to produce offspring with a large physiological and genetic variety. Crossing and selection strategies were used to further improve *M. heterothallica* in degrading biomasses such as sugarbeet pulp and spruce. The mechanisms behind improved biomass saccharification were understood by proteomics and genome analysis.

### **Conclusions**

This study showed the strategic strength of combining fungal diversity with specific selection strategies to find enzyme mixtures with interesting industrial properties.

**Biotechnology and industrial microbiology**

## **PREPARATION OF ACIDIC AMINOPHOSPHONATES USING FUNGI**

N. Kmieciak<sup>1</sup>, E. Żymańczyk-Duda<sup>1</sup>

<sup>1</sup>*Bioorganic Chemistry, Wrocław University of Technology, Wrocław, Poland*

### **Background**

Biotransformation is substrate transformation to desired product by using suitable kind of biocatalysts. Nowadays, it is an alternative tool for the development sustainable technologies for the production of chemicals and drugs. Aminophosphonates are analogues of amino acids in which a carboxylic moiety is replaced by phosphonic functionality or related groups. They are compounds with stable carbon to phosphorus bond and have wide range of biological activities and variety of applications in industry [Żymańczyk-Duda, *Phosphorus, Sulfur and Silicon*, **2008**, 183; Mucha A., *J. Med.Chem.* **2011**, 54]. Biosynthesis of chiral, organophosphorous compounds is still not fully explored field of science.

### **Objectives**

The aim of work was selection of the whole-cell biocatalysts with hydrolytic activity for preparation of phosphonate analogues of aspartic acid. Thus, biocatalytic methods, which allowed obtaining derivatives of aminophosphonic acids *via* biohydrolysis of lactam ring were elaborated.

### **Methods**

To obtain phosphonic analogue of aspartic acid *via* biohydrolysis of O,O-dimethyl-4-oxoazetidin-2-ylphosphonate, whole cells of *P. minioluteum* were used as a biocatalyst. NMR spectra interpretation allowed postulating possible mechanism of presented microbial conversion as amide bond hydrolysis. Biohydrolysis was only achieved in deionized water as bioconversion medium. Application of another reaction media caused partial splitting of the substrate during biotransformation process. The separation process required reverse phase chromatography to obtain product from biotransformation mixture.

### **Conclusions**

Presented method is simple and quite efficient. Application of *P.minioluteum* as a biocatalyst resulted in production of desired product with moderate yield. It means, that process is a good starting point for further scaling up the process.

**SELECT ANTIMICROBIAL PEPTIDES (AMPS) AS BACTERICIDAL AGENTS FOR EX VIVO STORED HUMAN PLATELETS**

C. Atreya<sup>1</sup>, K.V.K. Mohan<sup>1</sup>, M. Bosch-Marce<sup>2</sup>, S. Sainath Rao<sup>1</sup>

<sup>1</sup>OBRR/CBER, US FDA, Silver Spring, USA

<sup>2</sup>OVRR/CBER, US FDA, Silver Spring, USA

**Background**

Bacterial contamination of *ex vivo* stored human platelets and the transmittance of sepsis by platelet transfusion represent the highest infectious disease risk in transfusion medicine today.

**Objectives**

An alternative approach to detection of contaminated units is pathogen reduction technology that directly inactivates or prevents the replication of pathogens present in platelet products. We have developed a novel approach to pathogen reduction, one that promises to be more specific and less damaging to the platelet product and at the same time effective against 6 bacterial species common to transfusion of platelets.

**Methods**

The methodology is based on treatment of platelets with small synthetic peptides named PD1-PD4 derived from the thrombin-induced human platelet-associated antimicrobial proteins, and repeats of Arg-Trp (RW1-RW5), and their selected combinations. This treatment demonstrated microbicidal activity against *Staphylococcus aureus*, *Staphylococcus epidermidis*, *Escherichia coli*, *Pseudomonas aeruginosa*, *Klebsiella pneumoniae* and *Bacillus cereus* in the spiked platelet samples. We also demonstrated that AMP treated platelets maintain their *in vitro* properties during 7 days of storage. Preclinical evaluation of peptides PD3, PD4, and RW2-RW5 demonstrated that these AMPs do not adversely affect the human platelet recovery and survival in a SCID mouse model. We have further shown that the peptides are not immunogenic in rabbits, and do not affect platelet performance in *in vitro* tests.

**Conclusions**

The body of work presented here provides a proof of a concept that AMPs could be incorporated into a novel platelet-sparing pathogen reduction treatment and warrants further study.

**STABLE VECTORS FOR EFFICIENT GENE EXPRESSION IN RALSTONIA  
EUTROPHA H16**

S. Gruber<sup>1</sup>, P. Koefinger<sup>1</sup>, H. Schwab<sup>1</sup>

<sup>1</sup>Graz University of Technology, Institute of Molecular Biotechnology, Graz, Austria

**Background**

The Gram-negative  $\beta$ -proteobacterium *Ralstonia eutropha* H16 is primarily known for polyhydroxybutyrate (PHB) production and its ability to grow chemolithoautotrophically by using CO<sub>2</sub> and H<sub>2</sub> as sole carbon and energy sources. *R. eutropha* H16 has also attracted significant interest for its ability to metabolize heavy metals, to degrade a variety of chloroaromatic compounds or chemically related pollutants.

**Objectives**

The use of *R. eutropha* H16 as a production organism under chemolithoautotrophic growth conditions is favored. However, inducible expression systems are yet required for gene expression in *R. eutropha* H16. The aim of this work was to identify inducible expression systems for the use in *R. eutropha* H16 facilitating gene expression.

**Methods**

A family of efficient and highly stable plasmid expression vectors was created for the use in *R. eutropha* H16 by applying various biosynthetic methods.

**Conclusions**

The use of promoters derived from bacteriophage T5 was described in this work and hereby the J5 promoter proved to be the strongest promoter yet to be applied in *R. eutropha* H16. Moreover, the implementation of the RP4 partition sequence in plasmid design increased plasmid stability significantly and enables fermentations with marginal plasmid loss of recombinant *R. eutropha* H16 for at least 96 h. The utility of the new vector family in *R. eutropha* H16 is demonstrated by providing expression data with different model proteins and consequently further raise the value of this organism as cell factory for biotechnological applications including protein and metabolite production.

**Biotechnology and industrial microbiology**

## **SCREENING FOR CELLULOLYTIC ACTIVE NOVEL ANAEROBIC FUNGI**

V. Dollhofer<sup>1</sup>, I. Kinker<sup>1</sup>, M. Lebuhn<sup>1</sup>

<sup>1</sup>*Central Department for Quality Assurance and Analytics,  
Bavarian State Research Center for Agriculture, Freising, Germany*

### **Background**

Lignocellulosic plant material is degraded by anaerobic fungi (AF) with their rhizoid and various free and cellulosome-bound lignocellulolytic enzymes. AF could thus be used to improve biogas production from fiber-rich residues. AF were isolated from faeces of animals living on a high fiber diet. Screening them for the cellulolytic most active AF with conventional tests are labor intensive and time consuming, a quantitative Real-Time PCR (qPCR) routine for glycosyl hydrolase family 5 (GH5) endoglucanase should be developed as a suitable alternative.

### **Objectives**

New anaerobic fungal isolates should be checked and compared for their cellulolytic potential by parallel determination of GH5 mRNA production and conventional parameters. Thus anaerobic fungi with outstanding cellulolytic abilities shall be identified.

### **Methods**

To identify the best moment for mRNA extraction, growth curves of the isolates were recorded, and mRNA was extracted at several points. Additionally gas pressure was measured to see if mRNA production, growth and gas pressure developed accordingly. Reverse-transcribed cDNA was quantified in qPCR with primer system AF Endo designed to specifically detect GH5 endoglucanase of AF.

### **Conclusions**

Novel AF isolates were achieved from a Cameroon sheep, a Kiang, an alpine goat and a domestic yak. In experiments carried out with two of the isolates the GH5 RT-qPCR system tested successfully. GH5 mRNA production was maximal after 18h with similarly developing growth, gas pressure and mRNA level. Further AF species are being tested for their cellulolytic activity. A future study shall compare gained results with the real life cellulolytic ability of tested AF.

**INVESTIGATION OF SYNTHETIC LIGNIN BIOMODIFICATION BY PHANEROCHAETE CHRYSOSPORIUM : ANALYSIS OF STRUCTURAL CHANGES OF SYNTHETIC LIGNIN AND EFFECT OF MICROBIAL ENZYMES**

C.Y. Hong<sup>1</sup>, S.Y. Park<sup>1</sup>, S.H. Kim<sup>1</sup>, S.H. Ryu<sup>2</sup>, I.G. Choi<sup>1</sup>, I.G. Choi<sup>3</sup>

<sup>1</sup>Department of Forest Sciences, Seoul National University, Seoul, Korea

<sup>2</sup>Department of Forest Resources Utilization, Korea Forest Research Institute, Seoul, Korea

<sup>3</sup>Research Institute of Agriculture and Life Sciences, Seoul National University, Seoul, Korea

**Background**

These days, there has been a great interest in lignin as one potential renewable source for conversion into chemicals and materials. Lignin is complex and amorphous polymers, therefore, it needs to be modified to meet properties required for industrial uses.

White rot fungi secreting ligninolytic enzymes are promising for enzymatic modification, because they can degrade lignin selectively and more rapidly than other micorbes. Therefore, comprehending of biomodification process by white rot fungi is necessary for industrial application of microbial treated lignin.

**Objectives**

The biomodification of synthetic lignin by white rot fungus, *Phanerochaete chrysosporium*, was investigated in this study. The fungal secretomes and structural changes of the fungal treated synthetic lignin were examined.

**Methods**

Synthetic lignin used in this study was synthesized from coniferyl and sinapyl alcohol. This polymer, dehydrogenative polymer (DHP) was used as substrate to elucidate the mechanism of microbial modification of lignin.

Detailed structural analysis of lignin were conducted as follows : phenolic hydroxyl group of DHP was analyzed by aminolysis reaction, and the molecular weight and changes of ether bonds in DHP was analyzed by gel permeation chromatography and nitrobenzene oxidation method, respectively. For examining the effects of fungal secretomes in biomodification of synthetic lignin, protein contents by using protein chip and activities of ligninolytic enzymes were measured, respectively.

**Conclusions**

Consequently, this study is expected to help to understand the biomodification mechanism of synthetic lignin by *P. chrysosporium*, and to evaluate availability of *P. chrysosporium* in biomodification of lignin for value added application of lignin.

**HOMOLOGOUS AND HETEROLOGOUS EXPRESSION OF DEHYDROGENASES AND OXIDOREDUCTASES OF RALSTONIA EUTROPHA H16**

P. Koefinger<sup>1</sup>, Z. Magomedova<sup>1</sup>, S. Gruber<sup>1</sup>, H. Schwab<sup>1</sup>

<sup>1</sup>Graz University of Technology, Institute of Molecular Biotechnology, Graz, Austria

**Background**

*Ralstonia eutropha* is a Gram-negative, strictly respiratory facultative chemolithoautotrophic bacterium which can use H<sub>2</sub> and CO<sub>2</sub> as sole sources of energy and carbon in the absence of organic substrates. It has attracted great interest for its ability to degrade a large list of chloroaromatic compounds and chemically related pollutants. Furthermore it was already applied for the production of biodegradable polymer polyhydroxyalkanoates on an industrial scale. *R.eutropha* serves as a model organism for the mechanisms involved in the control of autotrophic carbon dioxide fixation, hydrogen oxidation and denitrification.

**Objectives**

We are interested in establishing specialized *R.eutropha* based cell factories by genetic engineering. The particular interest is constructing cells efficiently performing oxidoreductase reactions by overexpression of homologous and/or heterologous enzymes. One of the main types of oxidoreductase reactions is performed by dehydrogenases, which have a wide range of possible biotechnological applications.

**Methods**

A selection of alcohol dehydrogenases as well as short chain dehydrogenases of *R.eutropha* H16 was cloned and expressed in native versions in *E.coli* as well as in *R.eutropha* H16 in order to study basic functional capability of these enzymes. For each of the enzymes cofactor specificity and the substrate range, both for oxidation and reduction way was analysed in a photometric assay by the detection of NAD and thereby specific activity units were calculated.

**Conclusions**

Two of the tested enzymes showed high selectivity toward s-enantiomers for all tested secondary alcohols with NADP<sup>+</sup> as preferable cofactor. Furthermore a difference in enzyme activity depending on the expression host could be observed.

## **METHANOTROPH-CATALYZED BIOCONVERSION OF METHANE TO METHANOL**

E. Lee<sup>1</sup>

<sup>1</sup>*Department of Chemical Engineering, Kyung Hee University, Yongin, Korea*

### **Background**

Methane has attracted much attention as the alternative chemical feedstock and conversion of methane to methanol has attracted enormous interest. Indirect chemical conversion of methane to methanol is associated with a number of problems including low energy efficiency and high capital cost.

### **Objectives**

We investigated a batch methane-to-methanol conversion in high yield using *Methylosinus trichosporium* OB3b whole cells. Cultivation and conversion relevant parameters including air/methane ratio and copper concentration were optimized.

### **Methods**

*M. trichosporium* OB3b was cultured in a 600 mL joint flask with rubber septum containing 200 mL NMS medium with supply of 7:3 air/methane ratio at 30 °C. Various chemical inhibitors for methanol dehydrogenase were screened and added to accumulate methanol. Sodium formate was added as a reducing power source to maintain methane monooxygenase activity.

### **Conclusions**

In the presence of 100 mM potassium phosphate as MDH inhibitor, 0.4 g/L methanol was accumulated and more than 70% (mol methanol/mol methane) of methane was converted to methanol. Volumetric productivity of 0.049g/L/h was obtained in the batch reaction with *M. trichosporium* OB3b as the biocatalyst. Biocatalytic conversion using methanotrophic microorganism will offer an energy-efficient method in commercialization of methane-to-methanol.

**Background**

Increased amino acid requirement of malignant cells is exploited in metabolic antitumor therapy, e.g., enzymotherapies based on asparagine or glutamine deprivation. L-Asparaginase (L-Asparagine amidohydrolase; EC 3.5.1.1) which catalyzes the conversion of L-Asparagine to aspartic acid and ammonia is one of promising enzyme in pharmaceutical industries. A wide variety of microorganisms have L-asparaginase. Halophilic bacteria may contain L-asparaginase with novel immunological properties that can be used in hypersensitive patients because of modified surface structures.

**Objectives**

The main objective of this study was to optimize the culture conditions for L-asparaginase production by selected halophilic strain.

**Methods**

The effect of different concentrations of NaCl and glucose ranging from 0-10% and 0-1% respectively and the influence of different carbon sources such as saccharose, maltose, glucose and fructose on the enzyme production was evaluated by varying one factor at a time. The effect of pH (5–9) and temperature (25-35-45 °C) were also studied. After 72h incubation, the samples were collected by centrifugation for the determination of L-asparaginase activity by the nesslerization method.

**Conclusions**

A halophilic bacterium *Vibrio* sp. Strain GBFx3 which was isolated from Gomishan Lake at Golestan province of Iran was screened for L-asparaginase activity. The highest amount of L-asparaginase production was observed in 0.5% glucose or 0.5% saccharose as sole carbon source, 2.5% NaCl, 34°C and pH 8 which were 0.63, 0.5, 0.4 and 0.43 IU/ml respectively.

**DEVELOPMENT OF A POLYFUNCTIONING PROLONGED-ACTION BIOLOGICAL PREPARATION FOR CROP PRODUCTION BASED ON THE RHIZOSPHERE BACTERIAL STRAINS WITH ANTIFUNGAL AND PLANT-GROWTH STIMULATING PROPERTIES**

G. Ultanbekova<sup>1</sup>, A. Sadanov<sup>1</sup>, S. Aitkeldieva<sup>1</sup>, L. Trenozhnikova<sup>1</sup>, Y. Shorabayev<sup>2</sup>

<sup>1</sup>Committee of Sciences Ministry of Education and Sciences Republic of Kazakhstan, Institute of Microbiology and Virology, Almaty, Kazakhstan

<sup>2</sup>Committee of Sciences Ministry of Education and Sciences Republic of Kazakhstan, Branch "Applied microbiology" Institute of Microbiology and Virology, Kyzylorda, Kazakhstan

**Background**

Associations of the rhizosphere bacterial strains belonging to the genera *Pseudomonas* and *Azotobacter* simultaneously possess both antifungal and plant-growth stimulating properties and are the basis for new trends in the development of biological preparations for crop production.

**Objectives**

Strains *Pseudomonas* R-7 and *Azotobacter* A-6 isolated from the rhizosphere of tomato crops cultivated in Kazakhstan.

**Methods**

Antagonistic properties of the bacteria were studied using agar diffusion method against the pathogens of fungal diseases in tomatoes of the genera *Phytophthora*, *Fusarium*, *Alternaria*, *Cladosporium*. Growth-stimulating properties of bacteria were studied by inoculation of tomato seeds with a culture liquid of bacteria with a cell titer of  $n \times 10^9$ .

**Conclusions**

Strain *Pseudomonas* R-7 showed antagonism against phytopathogenic fungi: *Phytophthora* sp. - 19 mm, *Fusarium* sp. - 16 mm, *Alternaria* sp. - 23 mm, *Cladosporium* sp. - 18 mm. When using a strain *Azotobacter* A-6, the growth inhibition zone for *Phytophthora* sp. was 22 mm, *Fusarium* sp. - 24 mm, *Alternaria* sp. - 23 mm, *Cladosporium* sp. - 20 mm. Strain *Azotobacter* A-6 also enhanced the tomato germination capacity by 22.0% as compared with the control, increased the plant height by 15.5%, root length by 26.3%, plant mass by 15.0 %, and number of leaves by 33.3%.

A composition of the new biological preparation for crop production has been formulated based on the strains of rhizosphere bacteria *Pseudomonas* P-7 and *Azotobacter* A-6, compatibility of the strains under cultivation and storage examined, optimal ratio of bacterial microorganisms and soil extract in the combined culturing selected, ensuring the continued viability of cells within a scheduled storage period.

**CLONING AND OVEREXPRESSION OF A NEW LIP GENE FROM  
STENOTROPHOMONAS MALTOPHILIA PSI-1 - PURIFICATION AND PARTIAL  
CHARACTERIZATION OF THE RECOMBINANT LIPASE**

M. Parapouli<sup>1</sup>, A. Foukis<sup>1</sup>, P.Y. Stergiou<sup>1</sup>, M. Koukouritaki<sup>1</sup>, E. Karabika<sup>1</sup>,  
E.M. Papamichael<sup>1</sup>, A.S. Afendra<sup>1</sup>, E. Hatziloukas<sup>1</sup>

<sup>1</sup>Enzyme biotechnology and genetic engineering group, University of Ioannina,  
Ioannina, Greece

**Background**

Lipases catalyze esterification, interesterification and transesterification reactions and have gained serious attention for the production of sustainable biofuels, motivated by environmental concerns combined with the depletion of fossil fuels.

**Objectives**

The aim of this study was the isolation of new strains bearing high lipase activity in order to exploit their lipases in biofuel production.

**Methods**

42 environmental strains, isolated from sludge of a waste treatment facility (Psittaleia, Greece), were screened for the presence of lipase activity, using a rhodamine B procedure. One isolate, identified as *Stenotrophomonas maltophilia* (named Psi-1) by means of IGS-based molecular taxonomy, was selected for further analysis. A 1.203 bp amplicon of Psi-1 corresponding to a putative secreted lipase gene (as revealed by bioinformatic analysis) was cloned and overexpressed in a pET29c - *E. coli* BL21[DE3] system. The recombinant protein was purified using Ni-NTA chromatography. Lipase activity was verified by in-gel assays (zymograms) and photometric biochemical assays.

**Conclusions**

A novel lipase gene from a new *Stenotrophomonas maltophilia* isolate was identified, cloned and overexpressed. The recombinant enzyme was proved to exhibit lipase activity and has a potential as a catalyst for biofuel production.

**BIOCATALYZED KINETIC RESOLUTION OF CHIRAL DERIVATIZING AGENT: 2-BUTYRYLOXY-2-(ETHOXY-P-PHENYLPHOSPHINYL)ACETIC ACID WITH IMMOBILIZED WHOLE-CELL SYSTEM.**

M. Serafin<sup>1</sup>, E. Zymanczyk-Duda<sup>1</sup>

<sup>1</sup>Department of Bioorganic Chemistry, Wrocław University of Technology, Wrocław, Poland

**Background**

The use of enzymes as biocatalysts for the preparation of optically pure compounds is becoming a common method especially in the pharmaceutical industry [Nestl B.M., 2011, *Curr Opin Chem Biol*]. Obtaining enantiopure active compounds with a defined configuration appeared to be more desirable, not only because of effectiveness of such pharmaceuticals, but also because of safety requirements [Ogawa J., 2002, *Curr Opin Biotech*]. Immobilized whole-cells are one of the biocatalyst form that can be used in biotransformation processes. This system allows reusing biocatalyst, facilitates downstream processes and enhance the stability of the enzyme. Moreover, use of immobilized catalyst in flow reactor allows carrying out continuous processes.

**Objectives**

The aim of the study was the kinetic resolution of a racemic mixture of 2-butyryloxy-2-(ethoxy-P-phenylphosphinyl)acetic acid by biotransformation using immobilized whole-cell biocatalyst. *Penicillium oxalicum* has been reported as an active biocatalyst in the hydrolysis of tested compound in shake flask system [Serafin M., 2014, *Chemik*]. Optically pure products can find application as chiral discriminator and building block of defined absolute configuration in synthesis of biologically active compounds such as pharmaceuticals or pesticides.

**Methods**

The activity of biocatalyst, cells immobilized in two ways, was tested toward racemic mixture of starting compound. Products were analyzed by nuclear magnetic resonance spectroscopy <sup>31</sup>P NMR with the addition of quinine as a chiral solvating agent.

**Conclusions**

Simple and effective method of whole-cell immobilization was elaborated. Activity of biocatalyst was confirmed by hydrolysis of tested compound with 50% of conversion

degree and high enantiomeric excess. Developed system allowed to enlarged the scale of the process.

**Biotechnology and industrial microbiology**

## **ITACONIC ACID PRODUCTION IN ASPERGILLUS NIGER**

A. Hossain<sup>1</sup>

<sup>1</sup>*Molecular Biology&Microbial Food Safety, University of Amsterdam, Amsterdam, Netherlands*

### **Background**

The filamentous fungus *Aspergillus niger* has a long tradition of safe use in industry in the production of enzymes and organic acids. Furthermore, it can grow on a wide range of substrates under various environmental conditions and has an optimized pathway towards producing organic acids, as indicated by its high production titers of citric acid in submerged fermentations (>300 g/L). These features make it an interesting host for the production of itaconic acid (IA), a high-value building block chemical with a broad application potential in the chemical industry. We have successfully identified the IA production pathway of *Aspergillus terreus* and engineered it into *A. niger*. The resulting *A. niger* strain is able to produce IA at low levels.

### **Objectives**

In order to increase the yield we have tested various medium compositions and fermentation conditions. This resulted in an optimization of the fermentation medium and cultivation conditions, accompanied with an enhancement of yield and titer of IA production. Moreover, recently we have discovered a novel pathway found, to our knowledge, exclusively in *A. niger* that enables higher productivity, titer and yield of IA. This novel pathway provides a platform for further improvement of organic acid production in *A. niger*.

### **Methods**

Fungal transformation and fermentation

### **Conclusions**

This novel pathway enabled increased IA acid productivity, yield and titer.

**COMPARATIVE GENOMICS APPROACH FOR BUILDING A COMPLETE AGAROLYTIC SYSTEM**

I.G. Choi<sup>1</sup>, B. Park<sup>1</sup>, S. Lee<sup>1</sup>, E. Yun<sup>1</sup>, K.H. Kim<sup>1</sup>

<sup>1</sup>Department of Biotechnology, Korea University, Seoul, Korea

**Background**

In a marine carbon cycle, the metabolic pathway of agar is not fully understood. Agar is a recalcitrant hetero-polysaccharide. Many agarases are known to fragment agar polymer into disaccharide unit, neoagarobiose, that is split into two monomeric sugars (D-galactose and 3,6-L-anhydrogalactose). Metabolic fate of 3,6-L-anhydrogalactose is still mysterious.

**Objectives**

We aim to elucidate full repertoire of agarolytic system in nature not only for understanding the marine carbon cycle but also for construct a synthetic agarolytic system for biomass utilization.

**Methods**

Using experimentally verified functional agarolytic genes as a probe, we searched all available microbial genomes in the public databases and collected all microbial genomes having potential agarolytic activity. In comparative genomics approach, we combined three distinct procedures such as ortholog prediction, gene cluster analysis and transcriptomic analysis (RNAseq) of three genomes, *Saccharophagus degradans*, *Marinimicrobium agarolyticum* and *Vibrio* sp. EJY3, we predicted potential genes related to agar metabolic pathways.

**Conclusions**

The predicted gene set from comparative genomics was divided into several functional categories: i) metabolic enzymes, ii) regulatory proteins (e.g. transcription factor), iii) signaling proteins and transmembrane proteins. We identified phylogenetically conserved genes and designated those genes as the core gene set. By functional examination, we revealed new genes essential for 3,6-anhydrogalactose and designed a synthetic *E. coli* system metabolizing agar as a sole carbon source.

**FUNGAL STRAIN DEVELOPMENT FOR IMPROVED PROTEIN PRODUCTION:  
PROTEASE MUTANT APPROACHES AND GENOME MINING FOR NOVEL  
ENZYME DISCOVERY..**

P.J. Punt<sup>1</sup>, D. Nair<sup>1</sup>, J. Niu<sup>2</sup>, E. Lagendijk<sup>2</sup>, M. Arentshorst<sup>2</sup>, A.F.J. Ram<sup>2</sup>

<sup>1</sup>Microbiology, TNO, Zeist, Netherlands

<sup>2</sup>Molecular Microbiology & Biotechnology, IBL, Leiden, Netherlands

**Background**

Optimized protein production in filamentous fungi requires the availability of fungal strains with low levels of secreted protease activity in order to improve secreted protein levels, including shelf life. Already for several decades research has been carried out to obtain these type of mutants, leading to the isolation of mutants with very favorable characteristics, one being a mutation in a transcriptional regulatory gene, *prtT* (e.g. Punt et al;., 2008).

**Objectives**

Based on these results further improved strains have been developed using different selection approaches.

**Methods**

Controlled fermentation experiments with selected mutant strains revealed different improved characteristics, whereas full genome sequencing was carried out to identify the genetic basis of the mutant phenotypes. Identification of relevant protease-regulatory genes has also been carried out using collections of regulatory gene knock-out strains in *N. crassa* and *A. niger*.

**Conclusions**

Several examples of the use of selected mutant strains in our research to discover and produce novel hydrolytic enzymes will be presented.

## **DIRECT ETHANOL PRODUCTION FROM BAGASSE CLOSTRIDIUM CELLULOLYTICUM**

A. Dermanaki<sup>1</sup>, N. Zaman<sup>2</sup>, B. Nasernejad<sup>1</sup>, A. Salehi<sup>2</sup>, M.A. Amoozegar<sup>2</sup>

<sup>1</sup>Department of biochemical engineering,

Faculty of Chemical engineering Amirkabir university of Technology, Tehran, Iran

<sup>2</sup>Extremophiles Lab. Department of microbiology,

Faculty of biology and Center of Excellence in Phylogeny of Living Organisms College of science University of Tehran, Tehran, Iran

### **Background**

In recent years the direct process of ethanol production from lignocellulosic materials, has been considered greatly due to its efficiency and money-saving manner of manufacturing. Some *Clostridium* species such as *C.thermocellum* sp. and *C.cellulolyticum* sp. has received many attentions because of their extracellular enzyme production ability.

### **Objectives**

The ultimate goal of present study is evaluating the ethanol production ability of *C.cellulolyticum* from untreated bagasse and delignified bagasse as cellulose source. The ability of *C.cellulolyticum* H10 for direct consumption of cellulose, eliminate the hydrolysis processes and lowered the end cost of ethanol production and also decreased the environmental threats of the existing processes.

### **Methods**

In this study the bacterial strain was cultured in modified CM3 culture medium in anaerobic condition and after 20 days the produced ethanol was determined by gas chromatography, then cellulose was replaced with untreated bagasse and the ethanol production was examined. Untreated bagasse was delignified with three different pretreatment methods which include sodium hydroxide, sodium chlorite and acetic/nitric acid and the delignified outputs of all these delignification methods were used as carbon sources for bacterial growth and ethanol production were determined.

### **Conclusions**

Acetic/nitric acid delignification methods showed the highest delignification value with 86.7% lignin content decrease and the highest ethanol per cellulose yield with values of 0.19 (gr<sub>ethanol</sub>/gr<sub>cellulose</sub>).

**LOW CYTOSOLIC PH AS A SIGNAL FOR CELL SURVIVAL IN H<sub>2</sub>SO<sub>4</sub> STRESSED CELLS**

R. Mendonça de Lucena<sup>1</sup>, L. Dolz Edo<sup>1</sup>, S. Brul<sup>1</sup>, M. Antonio de Moraes Junior<sup>2</sup>, G. Smits<sup>1</sup>

<sup>1</sup>Molecular Biology and Microbial Food Safety, University of Amsterdam, Amsterdam, Netherlands

<sup>2</sup>Department of Genetics, Federal University of Pernambuco, Recife, Brazil

**Background**

In the process of bioethanol production yeast biomass is recycled using treatment with dilute sulfuric acid to control the bacterial population. This treatment can lead to loss of cell viability, with consequences on the fermentation yield.

**Objectives**

To understand and ideally enhance yeast cell survival in these conditions, we analyzed the functional cellular responses of *S. cerevisiae* to inorganic acid stress.

**Methods**

Was analyzed growth and intracellular pH (pH<sub>i</sub>) in low pH conditions, using the pH-sensitive GFP derivative ratiometric pHluorin expressed in the cytoplasm of the strains.

**Conclusions**

*S. cerevisiae* mutants in cell wall integrity (CWI) and calcium signaling have reduced growth and viability at a low external pH (pH<sub>ex</sub>) of 2.5. WT yeast showed evident defect in growth only at a pH<sub>ex</sub> of 1.5, showing that a functional cell wall biogenesis is crucial for survival. To our surprise, the CWI mutant showed enhanced viability at pH<sub>ex</sub> of 1.5 compared to pH<sub>ex</sub> 2.5. While at a pH<sub>ex</sub> of 2.5 the pH<sub>i</sub> was unaffected compared to pH<sub>ex</sub> 5.0, at pH<sub>ex</sub> 1.5 the pH<sub>i</sub> of a CWI mutant was reduced. This reduction by itself did not lead to loss of viability. Rather, artificial reduction of pH<sub>i</sub> at pH<sub>ex</sub> 2.5 rescued the CWI and Ca<sup>2+</sup> signaling mutants. Also, the lethal effect of low pH<sub>ex</sub> on CWI and Ca<sup>2+</sup> mutants takes place only in growing cells. However, a lowered pH<sub>i</sub> leads to a reduction in growth rate, and thus protects the cells from death. Likely, cytosolic pH is a signal that directs the growth-stress tolerance trade-off in yeast.

**PRELIMINARY STUDY ON ANTIMICROBIAL ACTIVITY OF BACTERIAL  
SIDEROPHORE**

K. Erkan<sup>1</sup>, D. Erdonmez<sup>2</sup>

<sup>1</sup>BIOLOGY, HACETTEPE UNIVERSITY, ANKARA, Turkey

<sup>2</sup>BIOLOGY, AKSARAY UNIVERSITY, AKSARAY, Turkey

**Background**

Bacteria must acquire iron by competing with environmental chelation. One mechanism for bacterial iron acquisition utilizes siderophores. These molecules are small-molecule chelating agents that have been isolated from many microorganisms. As a current study, siderophore is used to deliver an antibiotic payload, through production of siderophore linked antibiotics e.g. salmycins.

**Objectives**

In this study we aimed siderophore production from soil bacteria and detection of their antimicrobial activity .

**Methods**

Bacteria was isolated from soil samples. For detection of siderophore existence in these bacteria, Cas agar medium was used. Identification of siderophore producer bacteria were used 16srRNA analysis. The crude siderophore was produced and extracted from different soil bacteria. Antimicrobial effect of siderophore was determined on several pathogens (*Candida albicans* ATCC 10231, *Pseudomonas aeruginosa* 27853, *E.coli* 25922, *Staphylococcus aureus* 25923, *Bacillus subtilis* 6633, *Proteus mirabilis*, *Enterobacter aerogenes*).

**Conclusions**

As a result of study, we were observed that siderophore from soil bacteria have antimicrobial effect on pathogen microorganisms. Nowadays, These studies are thought as a new methods against the growing antibiotic resistance. Mimicry of Iron-uptake dependent mechanism will can be new approach in medicine.

**PSEUDOMONAS PUTIDA GENOME ANALYSIS: REPEAT SEQUENCES, MEGAPLASMID AND SOLVENT TOLERANCE REVISITED**

J. Kuepper<sup>1</sup>, N. Wierckx<sup>1</sup>, H.J. Ruijsenaars<sup>2</sup>, L. Blank<sup>1</sup>, J.H. de Winde<sup>3</sup>

<sup>1</sup>*Institute of Applied Microbiology, RWTH Aachen University, AACHEN, Germany*

<sup>2</sup>*R&D, Corbion Purac, Gorinchem, Netherlands*

<sup>3</sup>*Institute of Biology, Leiden University, LEIDEN, Netherlands*

**Background**

Solvent tolerant strains of the ubiquitous soil bacterium *Pseudomonas putida* are increasingly important for a wide range of industrial biotechnology applications. Because of its remarkable solvent and stress tolerance and its energy efficiency, *P.putida* S12 has been described as an important strain for production of value added aromatic compounds and for efficient whole cell biotransformation of HMF to FDCA (1, 2, 3, 4).

**Objectives**

We have undertaken detailed genome sequence analysis to identify and understand the background of solvent tolerance and energy efficiency in *P.putida* S12.

**Methods**

Whole genome sequencing was performed through Illumina HiSeq and PacBio RSII sequencing. Assembly was performed using the CLC Genomic Workbench (BLASR, SSPACE-LongRead scaffolder, Gapfiller version 1.10) and manual closure of remaining gaps. The completed genome sequence was subject to automated annotation by the NCBI Prokaryotic Genome Annotation Pipeline with manual annotation of prominent *Pseudomonas* features.

**Conclusions**

The full *P.putida* S12 genome consists of a 5.8 Mb circular genome and a 557 kb circular megaplasmid. Both the genome and the megaplasmid contain various mobile elements among which multiple copies of the ISS12-type repeat sequence (5). Location of ISS12 repeats and number variation in various strains indicate a role in acquisition and maintenance of solvent tolerance. In addition, gene composition of the megaplasmid indicates an essential role in instigation of solvent tolerance and resistance to other stress conditions. Further comparative analysis of the S12 genome will be presented together with functional analysis of predicted gene and

metabolic functions.

**EFFECT OF SILENCING ASPERGILLUS TERREUS YAP1 GENE, ON REACTIVE OXYGEN SPECIES (ROS) ACCUMULATION PATTERN AND LOVASTATIN BIOSYNTHESIS.**

J. Barrios-Gonzalez<sup>1</sup>, R.U. Miranda-Labra<sup>2</sup>, A. Pérez-Sánchez<sup>1</sup>

<sup>1</sup>*Departamento de Biotecnología, Universidad Autónoma Metropolitana-Iztapalapa, MexicoCity, Mexico*

<sup>2</sup>*cDepartamento de Biotecnología-Ciencias de la Salud, Universidad Autónoma Metropolitana-Iztapalapa, MexicoCity, Mexico*

**Background**

In an earlier work we found a ROS build up during lovastatin production phase, which coincided with *sod1* gene (oxidative stress defense enzyme) down regulation. Later, we showed that ROS regulate lovastatin biosynthetic genes. The mechanism by which ROS induce these genes is unknown, but it is considered to be through oxidative-stress-response transcription factor(s). Expression profiles suggested that *A. terreus* Yap1 is a candidate, although probably as a negative regulator. These findings could be used to design new genetic improvement methods.

**Objectives**

Study the role of Yap1 in the control of ROS and in lovastatin biosynthesis, in liquid submerged fermentation (SmF) and in solid-state fermentation (SSF). Also investigate if the perturbation in the ROS profile (caused by silencing *yap1*) can increase lovastatin production.

**Methods**

Silencing vector was constructed by ligation of a fragment of *Atyap1* gene to pGdpPki-RNAi vector. *A. terreus* TUB F-514 transformants were characterized. Lovastatin was quantified by HPLC, and ROS concentration by diclorofluorescein and gene expression by Northern Blot.

**Conclusions**

- 1) *yap1* silencing in *A. terreus* also caused decreased expression of gene *sod1*.
- 2) ROS build up began before schedule, reaching higher levels than in the parental.

Hence,

3) Gene *brlA* (regulator of conidiation) expressed earlier, and reached higher spore densities.

4) Also, gene *lovE* (lovastatin genes specific transcription factor) expression and lovastatin production started earlier and reached higher production levels than the parental in both culture systems. *yap1*-silenced mutants displayed lovastatin production increases of: 60% in SmF and 70% in SSF.

**GENOME SHUFFLING OF CLOSTRIDIUM BEIJERINCKII DSM 6423 FOR  
IMPROVED ISOPROPYL ALCOHOL PRODUCTION**

H. Máté de Gérando<sup>1</sup>, N. Lopes Ferreira<sup>2</sup>, A. Lopez Contreras<sup>1</sup>, F. Fayolle-Guichard<sup>2</sup>,  
L. Rudant<sup>2</sup>, F. Monot<sup>2</sup>

<sup>1</sup>Food & Biobased Research Institute, Wageningen University, Wageningen,  
Netherlands

<sup>2</sup>Biotechnology department, IFP Energies nouvelles, Rueil-Malmaison, France

**Background**

The limited supply and the negative environmental effects of the use of petroleum-derived fuels and chemicals have stimulated efforts for the development of more environmentally-friendly processes.

**Objectives**

The bacterial fermentation of carbohydrates is a promising way for the production of green chemicals and biofuels. My project aims at improving the efficiency of the anaerobic conversion of sugars by *Clostridium* species into C3 alcohols, namely isopropanol.

**Methods**

Genome sequencing and fermentation performance studies were carried out on multiple *Clostridia* strains including the natural Isopropanol-Butanol-Ethanol producing strain *Clostridium beijerinckii* DSM 6423 (NRRL B593). This strain was then used to generate, through N-methyl-N'-nitro-N-nitrosoguanidine (NTG) mutagenesis, 36 strains with altered fermentation profiles. The selective growth was performed in the presence of 3 suicide substrates or a high concentration of isopropanol (> 35g/L). Further improvement of this first set of mutated strains was achieved through genome shuffling which uses recursive protoplast fusion and offers the advantage of entire genome recombination (Gao, Zhao, Zhang, He, & Jin, 2012). Screening of the final strains was based on enhanced isopropanol tolerance, the best of them being able to tolerate concentrations of up to 50g/L.

**Conclusions**

Some improvement in isopropanol production compared to the wild type strain was attained with strains showing higher solvent yields and/or better selectivity. The best *Clostridium* strains obtained produce less butanol and more isopropanol allowing a more efficient bioprocess.

**EVALUATION OF OENOCOCCUS OENI EXOPOLYSACCHARIDES AS ENDOGENEOUS PROTECTIVE AGENTS FOR MALOLACTIC STARTER PRODUCTION**

M. Dimopoulou<sup>1</sup>, M. Favier<sup>2</sup>, J. Coulon<sup>2</sup>, V. Moine<sup>2</sup>, M. Dols-Lafargue<sup>1</sup>

<sup>1</sup>Grape and Wine Microbiology, Institut des Sciences de la Vigne et du Vin, Bordeaux, France

<sup>2</sup>R&D department of the Laffort Group, BioLaffort, Bordeaux, France

**Background**

The malolactic fermentation (FML) is an essential winemaking step driven by lactic acid bacteria. It takes place after the alcoholic fermentation and mainly consists in the conversion of L-malic to L-lactic acid, with subsequent improvement of the wine microbial stability, aroma and flavor. *Oenococcus oeni* is the most suitable species for driving FML in wine. *O. oeni* may come from the indigenous microflora found on grapes or in the cellar, or it may be massively added to wine as a malolactic starter. *O. oeni* malolactic starters are currently selected for their resistance to wine and their ability to produce polysaccharides is so far not considered. However, this property could be crucial for the protection of the bacteria during starter production and use.

**Objectives**

Our main objective was to examine whether the stimulation of the production of exopolysaccharides by the bacteria *in situ* before freeze drying could protect the bacteria and improve the survival rates towards productions steps but also during inoculation in wine.

**Methods**

The genome sequencing of 50 *O. oeni* strains permitted us to realize the inventory of the exopolysaccharides genes (RAST, Kaas). The exopolysaccharides analysis included the quantification (colorimetric and analytical methods) and phenotypic observation (optical and electron microscopy) of the produced exopolysaccharides. The production of *O. oeni* strains in a lyophilized form and their later inoculation in wine (freeze-drying, cells viability).

**Conclusions**

We observed that the tested strains showed specific survival behaviors, which were perfectly correlated with their EPS biosynthetic ability. The protecting role of the bacterial exopolysaccharides is now to be proposed at industrial level.

## **GLYCEROL PRE-TREATMENT OF SUGAR CANE BAGASSE AND EFFECT ON SUBSEQUENT ENZYME HYDROLYSIS**

E. Gomes<sup>1</sup>, E. Gomes<sup>1</sup>, M.M.S. Moretti<sup>1</sup>, D. Roberto<sup>1</sup>, C.C. Nunes<sup>1</sup>, S.R. Taboga<sup>1</sup>

<sup>1</sup>*Biology, Universidade Estadual Paulista-Unesp, Sao Jose do Rio Preto, Brazil*

### **Background**

**Background:** The second generation ethanol using agro-industrial waste is a promising alternative biofuel but the challenge is a technological approach to deconstruction the recalcitrant lignocellulose.

### **Objectives**

**Objective:** The present work aimed to study the effect of pre-treatment of sugar cane bagasse with microwave radiation in the presence of glycerol on chemical composition and the efficiency of subsequent enzymatic hydrolysis.

### **Methods**

Bagasse immersed in glycerol 10% were subjected to 2 min of microwave irradiation and the solid fractions resulting were used in the analysis of fibers, TGA, DTG, DSC, FTIR, X-ray and transmission electron microscopy and the liquid fractions were used to determine sugar and phenol contents. Samples of bagasse treated and untreated (control) were submitted to enzymatic hydrolysis for 24 to 72 h at 55 °C with enzymatic solutions obtained by the cultivation of *M. thermophila* M.7.7.

### **Conclusions**

Infrared spectra and thermal analysis showed that pre-treatment acted on the lignin and hemicellulose of bagasse. The hydrolysis with the enzyme produced by *M. thermophila* supplemented with  $\beta$ -glucosidase, afforded 74.0 mg/g and after 72 h the highest yield of reducing sugars was 240.9 mg/g, with  $\beta$ -glucosidase or not. The pre-treatment with microwave and glycerol improve in 40% the enzymatic hydrolyses of the cellulose.

**FUNGAL AND BACTERIAL CELLULOLYTIC ENZYMES TRCEL7B AND CFXYN11A ACTING IN SYNERGY DURING THE HYDROLYSIS OF SUGAR CANE BAGASSE**

*P. Pavón-Orozco*<sup>1</sup>, *H. Stalbrand*<sup>2</sup>, *M.E. Hidalgo-Lara*<sup>3</sup>, *A. Rosengren*<sup>2</sup>, *J.A. Santiago-Hernandez*<sup>3</sup>, *A.C. Ortega-Martínez*<sup>1</sup>

<sup>1</sup>Facultad de Ciencias Químicas, Universidad Veracruzana, Coatzacoalcos, Mexico

<sup>2</sup>Biochemistry, Kemcentrum Lund University, Lund, Sweden

<sup>3</sup>Biotecnología, CINVESTAV, Distrito Federal, Mexico

**Background**

Enzymatic bioconversion of lignocellulose to sugar monomers is performed by cellulases and hemicellulases acting synergically. Synergy among cellulases has been documented [1]; synergy between cellulases and accessory enzymes has been studied in cellulosome systems from *Clostridium cellulovorans* [2]. *Trichoderma reesei* and *Cellulomonas flavigena* are two not related cellulolytic organisms which produce enzymes with reported cellulase and xylanase activities, respectively[3,4]

[1] Appl. Biochem. Biotechnol. 2002. 101, 41-60.

[2] Bioresour. Technol. 2010101, 4472-4478.

[3] J. of Biotech 2001.87,179-191

[4] Bioresour.Technol. 2010. 101, 5539–5545.

**Objectives**

To evaluate synergy between two not complex enzymes, fungal cellulase (*TrCel7B*) and bacterial xylanase (*CfXyn11A*), in the sugar release of enzymatic hydrolysis of sugar cane bagasse.

**Methods**

Full length *CfXyn11A* xylanase from *C. flavigena* was expressed in *E.coli* [4]. Core *TrCel7B* was expressed in *T.reesei* [3]. Enzymatic bagasse hydrolysis was performed in equimolar ratios of cellulase(C) and xylanase(X): 100C,75C:25X,50C:50X,25C:75X, 100X. Release of sugar monomers was followed by HPLC after acid hydrolysis. Degree of synergy(D.S.) was quantified as the ratio of the specific activities of the enzymes in the hydrolysis mixtures divided by the sum of the individual specific activities at the concentration used.

**Conclusions**

Synergy between *CfXyn11A* and *TrCel7b* during bagasse hydrolysis was observed in glucose and xylose but not in arabinose release. The highest xylose and arabinose release observed at 12 h suggests a debranching role of the xylanase prior to cellulase hydrolysis occurring mainly after 24 h. However, a high D.S. observed in the 50C:50X at 12h, enforce the best performance of enzymes when they act together.

Glucose release

Synergy xylose release 12h

**DEVELOPMENT OF YARROWIA LIPOLYTICA AS AN OLEAGINOUS CELL  
FACTORY PLATFORM FOR PRODUCING NUTRACEUTICAL AND COSMETIC  
MATERIALS**

B. Yu<sup>1</sup>, J. Yoon<sup>1</sup>, J. Park<sup>1</sup>, A. Park<sup>1</sup>, H. Ahn<sup>1</sup>, J. Jang<sup>1</sup>

<sup>1</sup>IT Convergence Materials R&BD Group, Korea Institute of Industrial Technology,  
Cheonan, Korea

**Background**

*Yarrowia lipolytica* which has been extensively used as a model oleaginous yeast for producing heterologous proteins has capability to accumulate lipids (lipidbody, peroxisome etc) up to 50% of the DCW (dry cell weight). In addition, *Y. lipolytica* can be easily manipulated in gene deletion and insertion because it possesses a haploid genome and its genome sequence was completed and it is also known as GRAS (generally recognized as safe). Therefore, *Y. lipolytica* can be a high potential host strain in producing oleaginous (hydrophobic) and high value-added compounds used in nutraceutical and cosmetic materials which are hydrophobic and produced from plants by conventional extraction processes.

**Objectives**

In this study, we aim to construct basic and potential platform strain suitable for production of nutraceutical and cosmetic materials by using *Y. lipolytica*.

**Methods**

We used *Y. lipolytica* Po1g and constructed an ura3 auxotroph strain, *Y. lipolytica* (PolgDura3), in order to use URA3 blaster system which is a useful tool to carry out repeat genetic deletion and insertion on the genome. In addition, we constructed a *Y. lipolytica* (PolgDku70Dura3) in which Ku70 involved in non-homologous recombination was deleted to increase recombination efficiency in this strain.

**Conclusions**

We confirm that *Y. lipolytica* (PolgDku70Dura3) showed higher homologous recombination efficiency (>5 folds) than *Y. lipolytica* (PolgDura3). Next, we are introducing foreign genes involved in biosynthesis of some specific nutraceutical and cosmetic materials into *Y. lipolytica* (PolgDku70Dura3). This strain and genetic tool will be very useful to construct various customized strains for producing nutraceutical and cosmetic materials.

**MODULATION OF OXIDATIVE FOLDING TO IMPROVE RECOMBINANT PROTEIN PRODUCTION IN THE YEAST *SACCHAROMYCES CEREVISIAE***

M.M.M. Bisschops<sup>1</sup>, D. Petranovic<sup>1</sup>, J. Nielsen<sup>1</sup>

<sup>1</sup>*Systems and Synthetic Biology Department of Biology and Biological Engineering & The Novo Nordisk Foundation Center for Biosustainability, Chalmers University of Technology, Gothenburg, Sweden*

**Background**

The yeast *Saccharomyces cerevisiae* is widely used in biotechnology for the production of both bulk chemicals, like ethanol and organic acids, and higher-value compounds such as recombinant proteins, like pro-insulin. Recombinant protein production in *S. cerevisiae* induces different stress responses, including oxidative stress response. This is especially the case when the overall protein folding rate and the oxidative folding rate, i.e. the formation of di-sulfide bonds, are not properly balanced (1).

**Objectives**

In the present study we aim to develop metabolic engineering strategies to increase recombinant protein production by specifically adjusting oxidative folding.

**Methods**

Two industrially relevant proteins were selected based on different overall folding rates: pro-insulin and alpha-amylase. The oxidative folding of these proteins was modulated by A) altering the expression levels of several key players in oxidative folding, e.g. the thiol oxidases Ero1 and Erv2, and B) changing the number of possible di-sulfide bonds, i.e. the number of cysteine residues present.

**Conclusions**

The effects of these modulations on reactive oxygen species (ROS) levels, unfolded protein response, oxidative state, protein titers and overall physiology are monitored under strictly controlled growth conditions.

## **PRODUCTION OF BIO-OIL BY OLEAGINOUS YEAST**

*R.D. Wind<sup>1</sup>, E. van de Zilver<sup>1</sup>, K. Struijs<sup>1</sup>, B.C. Lokman<sup>1</sup>*

*<sup>1</sup>HAN BioCentre, HAN University of Applied Science, Nijmegen, Netherlands*

### **Background**

The Dutch government is stimulating the transition to a more biobased economy. Microbial oil can be produced from biomass in a green and sustainable way without competing to food crops by using oleaginous microorganisms such as yeast, fungi, bacteria and microalgae. At the HAN BioCentre a unique robust oil producing yeast strain has been selected called HBC025. The strain grows on a broad range of C5 and C6 sugars. The oil is accumulated by HBC025 in the form of triacylglycerols (TAGs) containing predominantly oleic (18:1), linoleic (18:2) and palmitic (16:0) acid. The produced microbial oil can be used as biodiesel but also in other applications such as paint, roads, floors and cosmetics.

### **Objectives**

Objective is the development of an economically feasible fermentation and extraction process for second generation oil production by HBC025.

### **Methods**

A fed-batch fermentation process was developed on glucose as model substrate. Hydrolyzed paper pulp was obtained from Parengo (Renkum, The Netherlands). Extraction methods tested were homogenization and enzyme assisted auto-lysis.

### **Conclusions**

Maximum productivity on glucose as substrate was 0.5 g bio-oil/l/h, which is comparable to the best lipid producing strains in literature (Ageitos et al. 2011). HBC025 was also able to grow on hydrolyzed paper pulp as substrate with the same growth rate. Calculations showed that the process can be economically feasible only in case components from the yeast biomass are also marketed besides the yeast oil.

**REVERSIBLE PSEUDOHYPHAE FORMATION IN PICHIA PASTORIS DURING HETEROLOGOUS PROTEIN PRODUCTION.**

S. Aggarwal<sup>1</sup>, N. maity<sup>1</sup>, S. Mishra<sup>1</sup>

<sup>1</sup>Department of Biochemical Engineering and Biotechnology,  
Indian Institute of Technology, New Delhi, India

**Background**

The methylotrophic *Pichia pastoris* yeast expression system is widely used for production of heterologous proteins. However, till now morphological changes have not been reported in *P.pastoris*. This study reports for the first time, a comprehensive characterization of Granulocyte colony stimulating factor (GCSF) expression in filamentous *P. pastoris*.

**Objectives**

To investigate the morphological changes in *P. pastoris* during protein production phase.

**Methods**

Mut<sup>s</sup> transformants, containing the GCSF-cDNA fused with modified kex2 cleavage site (in the  $\alpha$ -factor secretion signal) under the control of the *alcohol oxidase 1* promoter, were used in the study. The transformants were cultivated in BMGY (buffered glycerol complex medium) followed by BMMY (buffered methanol complex medium). Extracellular protein was quantitated by gel densitometry from 20-fold concentrated culture supernatant. A combination of methanol level and feeding strategy was developed to increase productivity of GCSF at fermenter level.

**Observation:**

Reversible Pseudohyphae was observed, resulting in increased surface to volume ratio with an increase in extracellular protein relative to the normal phenotype of spherical cells at same cell dry weight.

**Fig1.: Morphology of recombinants (A) Mut<sup>+</sup>(methanol utilization plus) and (B) Mut<sup>s</sup> (methanol utilization slow) strains of *P. pastoris*, SMD1168 cultivated in BMMY media + 0.4% histidine.**

## Conclusions

*P. pastoris* initiates a striking developmental transition to filamentous form, more so in the Mut<sup>s</sup> phenotype, that results in more surface to volume ratio, and affects productivity of the culture. To the best of our knowledge, data presented here opens the possibility of a filamentous form of *P. pastoris* for production of heterologous proteins.

## **HIGH-LEVEL PRODUCTION OF MONO-COMPONENT AND ENZYME MIXTURES IN MYCELIOPHTHORA THERMOPHILA**

C. Michielse<sup>1</sup>, J. Snelders<sup>1</sup>, P. Meeuwse<sup>1</sup>, J.P. Meijnen<sup>1</sup>, H. Visser<sup>1</sup>, J. Visser<sup>1</sup>

<sup>1</sup>R&D, Dyadic Netherlands, Wageningen, Netherlands

### **Background**

The fungus *Myceliophthora thermophila* C1 was developed into an efficient and versatile platform for high-level production of industrially relevant enzymes.

### **Objectives**

Through strain development strategies, two strain lineages were obtained that are currently being developed and exploited as production hosts. One lineage (HC) is able to produce and secrete high amounts of enzyme mixtures that contain large amounts of (hemi-) cellulases. The other lineage (LC) is impaired in its cellulase producing capability, resulting in low background-protein production. The LC strain has been further developed for high-level enzyme production. Total protein levels up to 80 g/L has been reached of which ~ 80% correlates to the introduced enzyme.

### **Methods**

By transforming the LC strain with selected C1 genes, a wide collection of strains was obtained, each of which produced mainly one enzyme. This has led to an enzyme library of over 100 functional enzymes of which many have been purified and characterized. The LC strain can also be designed and constructed in such a way that it produces only those enzymes that are functional under dedicated application conditions.

### **Conclusions**

In conclusion, *M. thermophila* was developed into a high-level protein-production platform. The HC strain is successfully applied to produce enzymes for the production of biofuels and biobased-chemicals. The LC strain is being used to produce single enzymes and defined combinations of enzymes. The obtained C1-enzyme library is a rich source for academic and industrial research. The properties of *M. thermophila* C1

make this fungus a highly suitable alternative for traditional fungal protein production hosts.

**NEW  $\phi$ BT1 SITE-SPECIFIC INTEGRATIVE VECTORS WITH NEUTRAL PHENOTYPE IN STREPTOMYCES**

N. González-Quiñonez<sup>1</sup>, P. Yagüe<sup>1</sup>, B. Rioseras<sup>1</sup>, M.T. López-García<sup>1</sup>, A. Manteca<sup>1</sup>

<sup>1</sup>*Biología Funcional and IUOPA, Universidad de Oviedo, Oviedo, Spain*

**Background**

Integrative plasmids are one of the best options to introduce genes in low-copy-number and a stable form into *Streptomyces*, but they generate mutations in their integration sites. Phage (PHI)C31, the most common integrative site used in *Streptomyces*, integrates at different positions (*attB* and pseudo-*attB* sites) in the *Streptomyces* genome generating different mutations and phenotypes. The less common integration site (PHI)BT1, integrates at a unique *attB* site localized in gene SCO4848 (*S. coelicolor* genome) or their homologues in other streptomycetes.

**Objectives**

Constructing an integrative plasmid with neutral phenotype.

**Methods**

Four plasmids were created modifying the  $\phi$ BT1 integrative vector pMS82: pNG1, in which the SCO4849 was introduced under the control of the promoter region of SCO4848 into pMS82 to restore the phenotype generated by the integration of the plasmid; pNG2, in which the promoter P<sub>ermE</sub><sup>\*</sup> was introduced into pNG1 to facilitate heterologous gene expression; pNG3 in which the *bla* gene for ampicillin resistance was included into pNG1 in order to facilitate selection in *E. coli*; and pNG4, in which the *bla* gene was introduced into pNG2.

**Conclusions**

The plasmids pNG1, pNG2, pNG3, and pNG4, are the only integrative vectors designed to produce a neutral phenotype when they are integrated in streptomycetes.

**THE INFLUENCE OF LACTIC ACID BACTERIA ADDITIVE ON THE LEVEL OF RESIDUAL WATER-SOLUBLE CARBOHYDRATES IN CORN SILAGE**

M. Duvnjak<sup>1</sup>, G. Kiš<sup>1</sup>, K. Kljak<sup>1</sup>, D. Grbeša<sup>1</sup>

<sup>1</sup>*Department of Animal Nutrition, University of Zagreb Faculty of Agriculture, Zagreb, Croatia*

**Background**

Ensilaging is a high moisture crop conservation method based on the fermentation of water soluble carbohydrates (WSC) guided by epiphytic microflora, specifically by lactic acid bacteria (LAB). LAB additives (inoculants) in ensilaging are used for promotion of optimal fermentation and rapid pH drop thus improving dominant nutrients preservation. However, the impact of inoculation on the level of residual WSC, which in high levels may result in silages aerobic deterioration, is not clear.

**Objectives**

During the present study, the application of LAB inoculant on residual WSC was investigated.

**Methods**

The three different yellow corn hybrid (Bc 418b, Bc 678 and Bc exp 6) produced in the same production conditions (31,01 – 38,52% DM) were ensiled in five replications in laboratory scale silos with and without Sil-All®4x4 LAB inoculant in a concentration  $1 \times 10^7$  CFU/g of fresh material. The silages were sampled on the 21<sup>st</sup> and the 60<sup>th</sup> day. The contents of lactic acid, WSC and pH were monitored.

**Conclusions**

The analyses showed that the inoculated silages had a significant increase ( $P < 0,05$ ) of lactic acid concentrations (g/kg DM basic) both on the 21<sup>st</sup> (31,45) and the 60<sup>th</sup> day (33,28) in contrast to silages without inoculant (21<sup>st</sup> 22,49; 60<sup>th</sup> 26,38). The same pattern was observed with pH. At the end of ensiling the difference in WSC content between silage with (8,63 g/kg DM) and without inoculant (7,39 g/kg DM) was not statistically significant ( $P > 0,05$ ). Inoculation of silages with Sil-All®4x4 stimulates lactic acid production and rapid pH drop whereas has no influence on the level of residual water-soluble carbohydrates.

## **FUNCTIONAL ANALYSIS OF FILIPIN TAILORING GENES FROM STREPTOMYCES FILIPINENSIS**

T.D. Payero<sup>1</sup>, C.M. Vicente<sup>1</sup>, A. Rumero<sup>2</sup>, E. García Barreales<sup>1</sup>, J. Santos-Aberturas<sup>1</sup>, A. de Pedro<sup>1</sup>, J.F. Aparicio<sup>1</sup>

<sup>1</sup>Molecular Biology, University of León, Leon, Spain

<sup>2</sup>Organic Chemistry, Universidad Autónoma de Madrid, Madrid, Spain

### **Background**

*Streptomyces filipinensis* is the industrial producer of filipin, a 28-membered non-glycosylated pentaene macrolide widely used for the detection and the quantitation of cholesterol in biological membranes.

### **Objectives**

Identification of tailoring genes belonging to the biosynthetic cluster for the biosynthesis of filipin, and generation of engineered derivatives for pathway elucidation.

### **Methods**

A region of 13778 base pairs of DNA from the *S. filipinensis* genome was isolated, sequenced, and characterized by gene replacement and complementation techniques.

### **Conclusions**

This set of genes shows synteny with the homologous *pte* genes from the filipin cluster of *S. avermitilis*, and includes two cytochrome P450 monooxygenase encoding genes, *filC* and *filD*, which are proposed to catalyze specific hydroxylations of the macrolide ring at C26 and C1' respectively. Gene deletion and complementation experiments provided evidence for their role during filipin III biosynthesis. Filipin III derivatives were accumulated by the recombinant mutants at high yield. These have been characterized by mass spectrometry following high-performance liquid chromatography purification thus revealing the post-polyketide steps during polyene biosynthesis. Two alternative routes lead to the formation of filipin III from the initial product of polyketide synthase chain assembly and cyclization filipin I, one through filipin II, and the other one through 1'-hydroxyfilipin I, both compounds being biologically active.

## **SCREENING OF LACTIC ACID BACTERIA FOR PRODUCTION OF BIOSURFACTANTS**

P. Shakeri Fard<sup>1</sup>, K.K. Andersen<sup>2</sup>, D. Otzen<sup>2</sup>, P.R. Jensen<sup>1</sup>

<sup>1</sup>*The National Food Institute Microbial Biotechnology & Biorefining, Technical University of Denmark, Kgs. Lyngby, Denmark*

<sup>2</sup>*iNANO and Department of Molecular Biology and Genetics, Aarhus University, Aarhus, Denmark*

### **Background**

Lactic acid bacteria (LAB) have been extensively used for thousands of years in food fermentation and nowadays in the industrial production of lactic acid and other metabolites.

### **Objectives**

In this study, the biosynthetic potential of lactic acid bacteria was exploited for biosurfactant (BS) production.

### **Methods**

66 Lactobacilli strains were screened for BS production when growing in different MRS-based media at static conditions. To determine BS production (extracellular and cell-bound), surface tension (ST) of supernatant and phosphate buffered saline (PBS) extract of the strains were measured by tensiometer. To determine critical micellar concentrations (CMC), PBS extracts of the strains remarkably reduced ST were diluted.

Pyrene solubilization assays were further done as a complementary assay to prove the presence of BSs. 1 mg of pyrene was distributed into glass test tubes and was subjected to supernatant and PBS extract of the strains in shaking conditions for 24h. The values were then compared with those of pyrene solubilization at the presence of rhamnolipid in different CMCs.

### **Conclusions**

The results showed there is a significant potential for BS production among the strains screened and 9 out of 66 Lactobacilli strains reduced ST of PBS extract between 19 and 22 units. The values are close to the data reported by Moldes *et al.* 2007 for *Lactobacillus pentosus* CECET-4023 (20 units) and Gudina *et al.* 2011 for *Lactobacillus paracasei* spp. *paracasei* A20 (22 units).

Pyrene solubilization assay can be taken into account as a promising method to identify BS-producing strains.

Concentrations and characterization of BSs produced are under investigation.

**CHARACTERIZATION OF SCO4439, A D-ALANYL-D-ALANINE CARBOXYPEPTIDASE INVOLVED IN SPORE CELL WALL MATURATION, SPORE RESISTANCE, GERMINATION AND MYCELIAL RESISTANCE TO VANCOMYCIN AND TEICoplanin**

*B. Rioseas<sup>1</sup>, P. Yagüe<sup>1</sup>, M.T. López-García<sup>1</sup>, N. González-Quironez<sup>1</sup>, E. Blinda<sup>2</sup>, F. Marinelli<sup>2</sup>, A. Manteca<sup>1</sup>*

<sup>1</sup>*Biología Funcional and IUOPA, Universidad de Oviedo, Oviedo, Spain*

<sup>2</sup>*Biotechnology and Life Sciences, University of Insubria, Varese, Italy*

**Background**

Streptomycetes are model microbes with complex developmental cycles. The last advances in system biology methodologies allowed the identification of large datasheets of proteins and genes differentially expressed during development whose biological function remains, in many cases, unexplored

**Objectives**

Characterization of the biological function of SCO4439, a developmentally associated D-alanyl-D-alanine carboxypeptidase (DD-CPase) overexpressed during the aerial mycelium and sporulation stages.

**Methods**

Strain: *Streptomyces coelicolor* M145

SCO4439::Tn5062 mutant was made according to **Fernández-Martínez (2011)**.

**Antonie Van Leeuwenhoek 99:515-522.**

**Conclusions**

1- SCO4439 is a multidomain protein harbouring a DD-CPase at its carboxyl end, and a putative cytosolic transcriptional regulator domain at the N-terminal end. Both domains are separated by a putative transmembrane region.

2- The DD-CPase activity was demonstrated '*in vitro*' to have a preference for DAla-DAla peptides, and to be inhibited by penicillin G.

3- SCO4439 was demonstrated '*in vivo*' to be involved in the resistance of the spores to heating and acid, in the spore swelling during germination, and in the resistance of the mycelium to glycopeptide antibiotics (vancomycin and teicoplanin).

4- The DD-CPase domain, together with the putative hydrophobic transmembrane region are highly conserved in *Streptomyces*, and the presence of both domains is essential to restore the phenotypes observed in the SCO4439::Tn5062 mutant. The conservation of the putative transcriptional regulator domain is much lower, and it is not necessary to restore the phenotypes detected in the SCO4439::Tn5062 mutant.

5- **SCO4439 controls PG cross-linking** releasing DAla from peptidoglycan lateral chains and reducing the substrate for the transpeptidation.

**6- The level of peptidoglycan cross-linking is regulating spore resistance and germination.**

## **AN EFFICIENT FED-BATCH FERMENTATION PROCESS: THE PRODUCTION OF STREPTOKINASE FROM E. COLI**

D. Goyal<sup>1</sup>, G. Sahn<sup>2</sup>, D. Sahoo<sup>3</sup>

<sup>1</sup>Department of Biotechnology, Central University of Rajasthan, Kishangarh, India

<sup>2</sup>Protein Science & Engineering, Institute of Microbial Technology, Chandigarh, India

<sup>3</sup>BERPDC, Institute of Microbial Technology, Chandigarh, India

### **Background**

Streptokinase is a therapeutic protein drug of bacterial origin. Its role in thrombolytic therapy has been well established. It is either produced from *Streptococcus*, its natural producer or from *E.coli* by recombinant means. The production from the former, however, is problematic due to low yield and simultaneous production of toxic endolytic chemicals. At IMTECH, the gene encoding for streptokinase from *Streptococcus equisimilis* was cloned and expressed in *E. coli* BL21 (DE3). Initially the expression in the latter was very low, hence the coding sequence was appropriately modified using molecular biology approaches and as a result of such optimizations, a high expression level of upto 80 mg l<sup>-1</sup> was obtained in shake flask cultivation.

### **Objectives**

The main objective of this study was to develop a bioprocess that could be used for mass scale production and purification of this high value therapeutic protein.

### **Methods**

To achieve the above objective, a fed-batch fermentation process was developed and optimized. Cultivation parameters like dissolved oxygen concentration (DOC), pH, media constituents and feed rate were carefully optimized and product yield was monitored.

### **Conclusions**

The process optimization resulted in an intracellular expression level of 1120 mg l<sup>-1</sup> in high cell density fermentation. This represented a 14-fold increase in production levels from flask to bio-reactor. Also the specific expression level *i.e.* gram protein produced per gram wet cell mass remained unchanged. This yield is the highest reported so far for recombinant Streptokinase.

<sup>7</sup>*Biology & Soft Matter Division, Oak Ridge National Laboratory (ORNL) - USA, Oak Ridge TN, USA*

**Background**

This research investigates the mechanism of lignocellulose degradation by brown rot fungi and potential industrial applications of this system. The brown rot non-enzymatic degradative mechanism is largely unexplored for use in biomimetic industrial/biorefinery applications and understanding the degradative mechanisms of brown rot fungi will lead to better methods of addressing the recalcitrance problems associated with lignin and crystalline cellulose in the pretreatment of biomass in biorefinery applications. A chelator mediated Fenton (CMF) system has evolved to substitute for components of the cellulolytic enzyme machinery in the brown rot fungi, generating an alternative efficient mechanism for depolymerization of biomass. The CMF system is unique among biological systems in being the only reported substrate deconstruction system based on oxygen radical chemistry that permits non-enzymatic deconstruction at a considerable distance (several microns) from the organism.

**Objectives**

Specific objectives of this research include: 1) Examining the morphology of the fungal sheath in a brown rotted fungal-wood complex to determine how the sheath may aid in the movement of CMF components and enzymes; and 2) Analyzing the structure of lignocellulose in early and late-stages of brown rot fungal degradation to assess how the CMF system modifies the wood cell wall non-enzymatically.

**Methods**

This research utilized several different techniques including the ORNL Bio-SANS (small angle neutron scattering) beam line to obtain the mechanistic information necessary to better characterize processes involved in non-enzymatic biodegradation of lignocellulose by brown rot fungi.

**Conclusions**

This research supports a CMF model system being employed by brown rot fungal organisms in lignocellulose deconstruction.

## **CHARACTERIZATION OF 3-KETOSTEROID-9 $\alpha$ -HYDROXYLASES IN RHODOCOCCUS RUBER STRAIN CHOL-4**

G. Guevara<sup>1</sup>, L. Fernández de las Heras<sup>2</sup>, J. Perera<sup>1</sup>, M. Navarro-Llorens<sup>1</sup>

<sup>1</sup>Biochemistry and Molecular Biology I, Universidad Complutense de Madrid, Madrid, Spain

<sup>2</sup>Microbial Physiology, Groningen Biomolecular Sciences and Biotechnology Institute, Groningen, Netherlands

### **Background**

Bacterial catabolism of steroid compounds provides a broad range of intermediaries needed for the synthesis of pharmaceutical steroid drugs such as 4-androsten-3,17-dione (AD) and 1,4-androstadiene-3, 17-dione (ADD). *Rhodococcus ruber* strain Chol-4, isolated from a sewage sludge sample, is able to grow in minimal medium supplemented with steroids, showing a large catabolic capacity.

The 3-Ketosteroid 9 $\alpha$ -Hydroxylase (KSH) is a key enzyme in the general scheme of bacterial steroid catabolism; it initiates the opening of the steroid ring by the 9 $\alpha$ -hydroxylation of the C9 carbon of 4-ene-3-oxosteroids (e.g. AD) or 1,4-diene-3-oxosteroids (e.g. ADD), transforming them into 9 $\alpha$ -hydroxy-4-androsten-3,17-dione (e.g. 9OHAD) or 9 $\alpha$ -hydroxy-1,4-androstadiene-3,17-dione (e.g. 9OHADD), respectively.

### **Objectives**

Study and characterization of 3-ketosteroid-9 $\alpha$ -hydroxylases in *Rhodococcus ruber* strain chol-4

### **Methods**

The ORF finder and the pDRAW32 programs were used to detect the ORFs. Determination of KSHs induced or constitutive transcription, along with the co-transcription of each cluster, was made by RT-PCR. Mutagenesis of both single, double and triple *kshA* and *kshB* were made by unmarked gene deletion. Growth studies were analyzed on different substrates.

### **Conclusions**

This work presents a set of data that clarifies KHAs specific roles in strain chol-4. We have characterized three different *kshA* and one *kshB* homologous ORFs in strain Chol-4. All of them present constitutive transcription and co-transcription. The mutants have shown differences in growing depending on the substrate.

**Biotechnology and industrial microbiology**

**TRANSPOSON Tn5-INDUCED MUTAGENESIS OF KANAMYCIN RESISTANCE  
RHIZOBIUM JAPONICUM**

S. Bhutada<sup>1</sup>

<sup>1</sup>*Department of Microbiology, Sanjivani Arts Commerce and Science College,  
Kopergaon, India*

**Background**

Transposase is an enzyme that binds to the ends of a transposon and catalyzes the movement of the transposon to another part of the genome by a cut and paste mechanism or a replicative transposition mechanism. *Rhizobium* is a genus of Gram-negative soil bacteria, many of which fix nitrogen. Nitrogen fixation is an important part of the nitrogen cycle. Plants cannot use atmospheric nitrogen (N<sub>2</sub>) they must use nitrogen compounds such as nitrates.

**Objectives**

The objective of this research was to determine whether at random transposon mutagenesis could be applied in genetic studies of *Rhizobium japonicum*. One major reason for this is that a range of defined mutations is not available.

**Methods**

In present study *R. japonicum* at frequencies sufficient to allow the isolation of large numbers of insertion mutants. The selection of Tn5 mutants was facilitated by the expression, in all the *R. japonicum* strains we have tested, of the Tn5 encoded kanamycin resistance. A number of auxotrophic and symbiotically defective, single, random transposon (Tn5) mutants were obtained in three slow-growing strains of different DNA homology and serogroups and the single fast growing strain of *R. japonicum*.

**Conclusions**

In conclusion, the diversity of auxotrophs detected and the isolation of symbiotic mutants suggests that transposon Tn5 can be used as a generalized mutagen to isolate a variety of mutants with defects in symbiotic nitrogen fixation. The analysis of such mutants should prove to be useful in elucidating the biochemical, genetic, and regulatory events involved in the *R. japonicum* which effectively nodulates certain Indian soybean cultivars

**FEMS-0988**

**Cell-cell communication / Quorum sensing**

**ACINETOBACTER STRAIN XB174 DEGRADES QUORUM SENSING SIGNAL OF RALSTONIA SOLANACEARUM, PREVENTS WILT AND PROMOTES GROWTH IN EGGPLANT**

G. Achari<sup>1</sup>, R. Ramesh<sup>1</sup>

<sup>1</sup>Plant Pathology, ICAR Research Complex for Goa, Panjim, India

**Background**

*Ralstonia solanacearum* is one of the most destructive plant pathogens and causes bacterial wilt in about 450 plant species worldwide. During infection, the pathogen primarily colonizes plant vascular system in high density leading to wilt and eventually plant death. Expression of virulence factors by the pathogen is regulated by a quorum sensing system activated 3-hydroxy palmitic acid methyl ester (3OH-PAME).

**Objectives**

The objective of this study was to determine 3OH-PAME degradation by bacterial strains isolated from eggplant xylem and to determine their wilt prevention and growth promotion ability in eggplant.

**Methods**

Bacterial strains (n = 6) were earlier isolated from xylem sap of eggplant. Using a bioassay involving indicator *R. solanacearum* strain AW1-3 and High Performance Liquid Chromatography Mass Spectrometry, 3OH-PAME degradation by bacterial isolates was estimated. Strain XB174 degraded 3OH-PAME and was evaluated for wilt prevention and growth promotion in eggplant under greenhouse conditions. XB174 was identified by 16s rRNA gene sequencing and its activity against Tween-20, Tween-80 and tributyrin was determined.

**Conclusions**

Among the strains screened using bioassay, only XB174 degraded 3OH-PAME to 3OH-palmitic acid. Specific activity of crude extracellular enzyme of XB174 towards 3OH-PAME was 17.78 U mg<sup>-1</sup>. XB174 prevented wilt (55.0 ± 7% over control) and improved growth (19.2 ± 10% more growth promotion efficacy over control) in eggplant. XB174 is identified as *Acinetobacter* sp., degraded Tween-20, Tween-80 and tributyrin.

The study reveals the quorum quenching activity of *Acinetobacter* strain XB174 against *R. solanacearum*. After additional screening, extracellular enzyme from XB174 may have applications in agriculture and industries.

**FUNCTIONAL CHARACTERIZATION OF A LUXR TYPE REGULATOR, ABAR IN ACINETOBACTER BAUMANNII: INVOLVEMENT OF ABAR IN PATHOGENESIS**

C. Choi<sup>1</sup>, M. Oh<sup>2</sup>, D. Kim<sup>1</sup>, H. Park<sup>1</sup>, E. Lee<sup>1</sup>, B. Subhadra<sup>1</sup>

<sup>1</sup>Microbiology, Chungnam National University School of Medicine, Daejeon, Korea

<sup>2</sup>Microbiology, Dankook University, Cheonan, Korea

**Background**

Quorum sensing is a cell to cell communication system that coordinates gene expression in many bacterial species. It has become an increasingly interesting target for the development of alternative drugs for treating multi-drug resistant *Acinetobacter baumannii* infection. However, the role of quorum sensing system in *A. baumannii* has not been characterized.

**Objectives**

The aim of this study is to characterize the functions of AbaR, a putative LuxR type receptor, using an isogenic mutant, and to shed some light on to the development of effective alternative drugs targeting AbaR.

**Methods**

The disruption of *abaR* in *A. baumannii* lead to significant decrease in biofilm formation. In addition, the pellicle production and swarming motility of the *abaR* mutant was substantially decreased compared to that of wild-type. The *abaR* mutant complemented with the intact *abaR* gene reverted back to that of wild-type capable of producing biofilm and displaying swarming motility. The survival rate of mice infected with the *abaR* mutant strain was significantly high than that of those infected with the *A. baumannii* wild-type. Also, whole transcriptome analysis was performed in order to compare the gene expression in wild-type and *abaR* mutant strains. Furthermore, chemical screening was carried out for the possible quorum quenching compounds targeting AbaR.

**Conclusions**

The data from the current study reveals that AbaR plays an important role in *A. baumannii* pathogenesis and this regulator protein could be a putative target of quorum quenching compounds. Supported by KHIDI (grant number: HI14C0257)

## **HOW DOES HAMAMELITANNIN INCREASE STAPHYLOCOCCUS AUREUS BIOFILM SUSCEPTIBILITY TOWARDS GLYCOPEPTIDES?**

G. Brackman<sup>1</sup>, F. Van den Driessche<sup>1</sup>, T. Coenye<sup>1</sup>

<sup>1</sup>Lab of Pharmaceutical Microbiology, Ghent University, Gent, Belgium

### **Background**

*Staphylococcus aureus* biofilm-associated infections are difficult to treat and novel targets are needed to combat these infections. The QS modulator hamamelitannin increases susceptibility of *S. aureus* biofilms towards vancomycin *in vitro* as well as *in vivo*. However, it is unclear how HAM affects susceptibility.

### **Objectives**

Elucidate the mechanism of action of HAM at the molecular level.

### **Methods**

Two parallel strategies were followed. First, we evaluated the effect of HAM on biofilms of *S. aureus* strains with mutations in the QS systems or in genes involved in biofilm formation and virulence. Secondly, using illumina sequencing we identified genes that were differentially expressed in untreated biofilms and biofilms treated with VAN alone or in combination with HAM. Results obtained with both strategies were further investigated using the appropriate tools.

### **Conclusions**

No loss in HAM activity was observed for most of the mutants. In contrast, HAM did not affect biofilm susceptibility of *S. aureus* strains with mutations in the QS system. Using sequencing, we identified a large number of genes that were differentially regulated after treatment (e.g. genes involved in biosynthesis of lysine, D-alanine, glutamine consuming pathways and virulence). This indicates that HAM reduces the upregulation of peptidoglycan biosynthesis normally observed after treatment with VAN. This possibly leads to the increased susceptibility of *S. aureus* biofilm cells towards VAN. Our results further indicate that combination therapy could positively affect morbidity since the upregulation of virulence factors observed for VAN treatment are not observed when VAN is combined with HAM.

**ACYL HOMOSERINE LACTONE-BASED QUORUM SENSING AND BIOFILM FORMATION IN THE PHOTOSYNTHETIC BACTERIUM RHODOSPIRILLUM RUBRUM S1H**

C. Condori<sup>1</sup>, N. Leys<sup>1</sup>, R. Wattiez<sup>2</sup>, F. Mastroleo<sup>1</sup>

<sup>1</sup>Microbiology, Belgian Nuclear Research Centre - SCKCEN, Mol, Belgium

<sup>2</sup>Proteomic and Microbiology, University of Mons, Mons, Belgium

**Background**

MELiSSA (Micro-Ecological Life Support System Alternative) has been conceived as a 5 compartments microorganisms and higher plants recycling system for long haul space flights. *Rhodospirillum rubrum* S1H colonizes compartment II and grows under light anaerobic conditions (LAN) using acetate as carbon source (MELiSSA conditions). Previous work reported that continuous culture of the bacterium in a photobioreactor lead to thick biofilm formation, leading to bioreactor arrest.

**Objectives**

The aim of this research is to investigate the relation of the quorum sensing (QS) system and biofilm formation of *R. rubrum* S1H (wild type, WT) under MELiSSA relevant culture conditions.

**Methods**

In this context we have constructed a mutant strain named M68 that does not produce acyl homoserine lactones (AHLs) signaling molecules. The transcriptomic and proteomic profiles and phenotype of WT and M68 under MELiSSA conditions were compared. In addition, the biofilm development of WT and M68 in a flow cell system under light microaerobic conditions was studied.

**Conclusions**

*R. rubrum* has a cell-to-cell communication system based on AHLs which regulates 8% (326 genes) of the genome of M68. In *R. rubrum* QS regulates pigmentation, photosynthesis, energy generation, carbon metabolism, motility and biofilm formation. To our knowledge this is the first report where QS is linked to biofilm formation in *R. rubrum* S1H under light microaerobic conditions. Further flow cell experiments under MELiSSA conditions will help us to study biofilm formation and to test substances with known anti-biofouling properties.

**DETERMINING OF RELATIONSHIP BETWEEN SIDEROPHORE PRODUCTION AND QUORUM SENSING MOLECULES ON MULTIDRUG-RESISTANT ACINETOBACTER BAUMANNII**

D. Erdonmez<sup>1</sup>, N. Aksöz<sup>2</sup>

<sup>1</sup>BIOLOGY, AKSARAY UNIVERSITY, AKSARAY, Turkey

<sup>2</sup>BIOLOGY, HACETTEPE UNIVERSITY, ANKARA, Turkey

**Background**

In addition to causing various infections, *Acinetobacter* species are described as nosocomial pathogens. These species are increasingly developing resistance against antibacterial agents due to their capability to adapt to any environment. *Acinetobacter* species develops these capabilities against their environment by quorum sensing (QS) mechanism which is a bacterial communication or ambient sensing mechanism. Quorum sensing systems needed for iron uptake comprising genes required for siderophore biosynthesis.

**Objectives**

In this work, effect of signal molecules on siderophore biosynthesis and its relation with QSS in *MDR A.baumannii* were studied.

**Methods**

Twenty strains of MDR *A.baumannii* from different clinical specimens were identified by standard methods. QSS molecules were identified by cross-validation test and siderophore biosynthesis was evaluated on CASagar and thin layer chromatography(TLC). AHL profiles were determined by using *Agrobacterium tumefaciens* biosensor strains (A136 or NTL1). QSS molecules combined with the biosensor strains were separated by TLC from each other.

**Conclusions**

According to results of the study, it was found out that all of the MDR *A. baumannii* strains produced the following miscellaneous QSS molecules in varying amounts: C8-HSL, C10-HSL and C12-HSL and these strains produced hydroxamate- and catechol-type siderophores. Iron uptake in the environments is thought to be a direct relationship with quorum sensing system. The variations in the amounts and types of signal molecules were observed to affect virulence properties. QSS molecules can be used as target molecules in medical therapy. The study provides new information about the virulence factors for the better understanding of the infection properties

of *A.baumannii* in the host.

**BIO-CONTROL APPLICATION OF BACILLUS QUORUM SENSING ON AFLATOXIGENIC FUNGI THROUGH THEIR INTER-KINGDOM CROSS-TALK**

E. Esmailshirazifard<sup>1</sup>, S. Moschos<sup>1</sup>, T. Keshavarz<sup>1</sup>

<sup>1</sup>Life Sciences, University of Westminster, London, United Kingdom

**Background**

Quorum sensing molecules (QSM) are involved in the regulation of complicated processes helping bacterial population benefit from their cell-density. Prokaryotes and eukaryotes' co-evolution raises the prospect of the existence of inter-kingdom signalling pathways. The role of hormone-like molecules in cell communication approves QS role in this cross-talk. Bacterial antagonistic activity against fungi is considered as an inter-kingdom talk. *Bacillus* and *Pseudomonas* have the ability to inhibit *Aspergillus* growth and aflatoxins production. Screening of antagonistic bacteria against *Aspergillus flavus* in vitro, *Bacillus subtilis* was identified with high antifungal activity.

**Objectives**

*Bacillus licheniformis* has industrial application due to its production of antimicrobial compounds and is related to *B. subtilis* genetically, whose control of competence-sporulation is regulated by a QS mechanism. QS in *B. subtilis* is regulated by ComX pheromone. As QS genes have been identified in *B. licheniformis* NCIMB-8874, our study has focused on QSM in this strain.

**Methods**

To investigate cell-cell communication, the comQX locus was sub-cloned into a shuttle vector which was expressed in *E. coli* and pheromone was isolated by reverse phase chromatography.

**Conclusions**

Pheromone as a QSM is potential signal for communicating between kingdoms and could be applied for bio-control purposes. Identification of new antifungal peptides against *A. flavus* could lead to the development of biotechnological strategies which facilitate control of aflatoxin contamination.

## **THE FUNCTIONAL UNITS OF QUORUM SENSING (QS) IN AMMONIA-OXIDIZING BACTERIA**

J.I.E. Gao<sup>1</sup>, G. Zhuang<sup>1</sup>, X. Zhuang<sup>1</sup>, A. Ma<sup>1</sup>

<sup>1</sup>Key Laboratory of Environmental Biotechnology, Research Center for Eco-Environmental Sciences Chinese Academy of Sciences, Beijing, China

### **Background**

Quorum sensing (QS) is an important form of cell-to-cell communication that regulates gene expression in response to fluctuations in cell density. One of the best-studied examples of quorum sensing is *N*-acyl homoserine lactones (AHLs)-mediated cell-cell communication in gram-negative bacteria. While it have been able to describe the QS system in some individual microorganisms for some time now, the functional QS system of nitrifying bacteria has not been completely proved to date.

### **Objectives**

Testing the existence and characterization of quorum-sensing signal produced by nitrifying bacteria (like *Nitrosomonas europaea*, *Nitrosospira multiformis*), and the functional QS signal synthase, the cognate receptor responding to the synthase-generated signal in these microorganisms.

### **Methods**

The AHLs product was obtained by extracting bacteria culture supernatants with acidified ethyl acetate, and then detected by AHLs biosensor and liquid chromatography-mass spectrometry (LC-MS). To identify gene(s) encoding AHL synthases and transcriptional activators, the genome of related nitrifying bacteria was searched for genes with similarity to all QS-related genes. AHL synthases gene was expressed in the heterologous host *E. coli* BL21. Putative AHLs in the recombinant extract were confirmed by comparing the retention times and mass spectra from LC-MS with those of standard AHLs. As a test of the hypothesis that these AHLs were cognate signals of probable receptor, we also examined the solubility of the R protein.

### **Conclusions**

We have shown a LuxI/R type QS signal synthase and regulator in an ammonia-oxidizing strain, and the results provide an opportunity to complete the QS regulatory networks.

**ROLES OF QUORUM SENSING-DEPENDENT GLYOXYLATE CYCLE IN  
BURKHOLDERIA GLUMAE**

E. Goo<sup>1</sup>, H. Ham<sup>1</sup>, Y. Kang<sup>1</sup>, J. Oh<sup>1</sup>, J. An<sup>1</sup>, I. Hwang<sup>1</sup>

<sup>1</sup>Department of Agricultural Biotechnology, Seoul National University, Seoul, Korea

**Background**

*Burkholderia glumae*, the causal agent of rice panicle blight, contains a single LuxI-R type quorum sensing (QS) system. TofI synthesizes *N*-octanoyl homoserine lactone (C8-HSL), which is recognized by TofR to regulate various private and public goods. The complex of TofR and C8-HSL activates expression of genes for toxoflavin and flagellar biosynthesis and an IclR type transcriptional regulator gene, *qsmR*. Among QS-dependent public goods, oxalate is produced to protect cells from ammonia-mediated alkaline toxicity in LB during stationary phase. RNAseq analysis indicated that expression of isocitrate lyase gene (*aceA*) might depend on QsmR.

**Objectives**

We aimed to confirm that glyoxylate cycle is controlled by QS and to determine roles of QS-dependent glyoxylate cycle in *B. glumae*.

**Methods**

To ascertain control of glyoxylate cycle by QS, we measured expression level of *aceA* and malate synthase (*glcB*) genes from the chromosomal Tn3-*gusA* fusions in each gene in the wild type and the QS mutants. Electrophoretic mobility shift assays were performed using the promoter regions of *aceA* and *glcB* and purified QsmR. AceA enzyme activity was determined by measuring the formation of glyoxylate-phenylhydrazine in the presence of phenylhydrazine and isocitrate at 324 nm. Levels of oxalate production of each strain were measured by using oxalate assay kit (Libios).

**Conclusions**

Glyoxylate cycle is controlled positively by QS and is important for oxalate biosynthesis in *B. glumae*.

**INVOLVEMENT OF RALFURANONE PRODUCTION IN THE VIRULENCE OF  
RALSTONIA SOLANACEARUM OE1-1**

K. Kai<sup>1</sup>, H. Ohnishi<sup>1</sup>, Y. Mor<sup>2</sup>, A. Kiba<sup>2</sup>, K. Ohnishi<sup>3</sup>, Y. Hikichi<sup>2</sup>

<sup>1</sup>Graduate School of Life and Environmental Sciences, Osaka Prefecture University, Sakai, Japan

<sup>2</sup>Laboratory of Plant Pathology and Biothechnology, Kochi University, Kochi, Japan

<sup>3</sup>Research Institute of Molecular Genetics, Kochi University, Kochi, Japan

**Background**

*Ralstonia solanacearum* causes a destructive disease called “bacterial wilt” in numerous plant species. Its virulence is controlled by the transcriptional regulator PhcA, the activity of which is, in turn, regulated in a cell-density dependent manner, termed quorum sensing.

**Objectives**

We herein described the identification and characterization of ralfuranones J–L, new PhcA-regulated secondary metabolites, and the known derivatives, ralfuranones A and B, from *R. solanacearum* strain OE1-1.

**Methods**

Their structures were determined by spectroscopic and chemical methods. These ralfuranones were also detected in vascular exudates from host plants infected with OE1-1. Deletion of *raIA*, which encodes an enzyme for ralfuranone biosynthesis, reduced the virulence of OE1-1 in tomato plants. Virulence was restored by complementation of the *raIA* gene.

**Conclusions**

The results suggest that ralfuranones play important roles in the virulence of OE1-1.

**Cell-cell communication / Quorum sensing**

**LOSS OF QUORUM SENSING SYSTEM CAUSES OUTER MEMBRANE VESICLE FORMATION IN BURKHOLDERIA GLUMAE**

Y. Kang<sup>1</sup>, E. Goo<sup>1</sup>, J.H. An<sup>1</sup>, I. Hwang<sup>1</sup>

<sup>1</sup>Agricultural Biotechnology, Seoul National University, Seoul, Korea

**Background**

*Burkholderia glumae* possesses one LuxI-R type quorum sensing (QS) system. The QS system of *B. glumae* activates expression of oxalate biosynthesis genes to avoid ammonia-mediated alkaline toxicity as results of amino acid catabolism. However, QS mutants do not produce oxalate, which causes population crash in stationary phase.

**Objectives**

We aimed to address a question whether QS mutants experience envelop stress to cause vesicle formation.

**Methods**

Outer membrane vesicles (OMVs) were purified from QS mutants using density-gradient sedimentation techniques. Total proteins were identified from the OMVs by LC-MS/MS analyses. The membrane ultrastructure of QS mutants and their vesiculation were visualized by transmission electron microscopy (TEM) after ultrathin sections.

**Conclusions**

Total 368 vesicular proteins were identified from the OMV proteomes. Most vesicular proteins were found to be involved in molecular functions associated with transporter, protein secretion, and protein localization. TEM revealed that periplasmic space of QS mutants is swollen due to hyperhydration in exponential phase. Previous metabolome analyses showed that serious imbalance of glutamate in QS mutants, which suggests that QS mutants might experience a turgor pressure problem. We propose that OMVs of *B. glumae* might be induced to relieve turgor stress caused by imbalanced metabolism.

**THE ACTIVATION OF STAPHYLOCOCCUS EPIDERMIDIS SORPTION BY THE AUTOGENOUS LOW MOLECULAR WEIGHT FACTORS**

*D. Eroshenko<sup>1</sup>, V. Korobov<sup>1</sup>*

*<sup>1</sup>Laboratory of microorganisms' biochemical development,  
Institute of Ecology and Genetics of Microorganisms UB RAS, Perm, Russia*

**Background:** The bacterial occupation of a surface can be associated with the production and realizing of compounds which can optimize and accelerate this process.

**Methods:** The exponential phase cells of *Staphylococcus epidermidis* strain GISK 33 were washed twice (0.85% NaCl) and diluted to  $10^7$  CFU/ml (PBS, pH 7.2). The cell-free medium filtrates were obtained after the *S.epidermidis* sorption on a polystyrene and glass surface for 60 min. The effect of filtrates media on the bacterial cell adhesion was evaluated. In addition these filtrates were subjected to MALDI-TOF analysis and treatment by trypsin and proteinase K (100 mkg/ml, 37°C, 2 h) with followed by enzymes separation by membrane filtration (10 kDa).

**Conclusions:** The cell-free medium after *S.epidermidis* adhesion to the polystyrene had a stimulating effect on the adhesion of the same bacterial cells on the polystyrene surface compare to the filtrates after the bacterial contacting with the glass surface. The level of found by MALDI-TOF analysis compounds with low mol. weight 552, 574 and 596 Da in the filtrate from polystyrene which showed the greatest stimulatory effect on bacterial adhesion was higher than the glass filtrate. The peptide nature of these compounds was proved by the reduction of the stimulatory effect on the *S.epidermidis* 33 adhesion to the control level (PBS) after the treatment by proteases. Thus, the evidence of the possibility of autoregulation of *S.epidermidis* cell adhesion by using the low molecular weight peptide compounds was provided.

**ISOLATION AND PARTIAL CHARACTERIZATION OF A SPORULATION PEPTIDE FROM ENTEROTOXIN-POSITIVE CLOSTRIDIUM PERFRINGENS**

R. Labbe<sup>1</sup>, C. Kuo<sup>1</sup>, Z. Yin<sup>1</sup>

<sup>1</sup>Food Science, University of Massachusetts, Amherst, USA

**Background**

The enterotoxin produced by *Clostridium perfringens* is associated with the sporulation process. The regulation of this process is therefore of interest. We previously described the presence of a low MW, heat-stable compound in the culture fluids of this organism which stimulated the sporulation of homologous and heterologous strains, including enterotoxin-positive strains.

**Objectives**

Isolate and characterize the presumptive peptide involved in promoting sporulation of *Clostridium perfringens*

**Methods**

The peptide was isolated from a defined medium following Sephadex LH-2, SP Sephadex, DEAE Sephadex chromatography followed by HPLC using C8 and C18 columns. Mass spectroscopy, amino acid analysis, and N-terminal sequencing revealed a 1018 Da peptide composed of glutamic acid, glycine, alanine, and an unidentified residue. N-terminal sequencing suggests a branched chain or cyclic structure. The isolate compound was effective in stimulating sporulation of *C. perfringens* in a dose-dependent manner at levels <2 nm/l and differs from sporulation-stimulating peptide previously identified from *Bacillus subtilis* and which was ineffective in promoting sporulation of *C. perfringens*.

**Conclusions**

We believe the peptide functions as a quorum-sensing molecule. The identification of a sporulation signal could help identifying the molecular events leading to sporulation and enterotoxin production by this organism.

**QUORUM SENSING INHIBITORY AND ANTI-BIOFILM ACTIVITY OF DIETARY PLANTS CULTIVATED IN KOREA**

N. Lee<sup>1</sup>, S. Oh<sup>1</sup>, H. Chang<sup>1</sup>, S. Choi<sup>1</sup>, M. Woo<sup>1</sup>

<sup>1</sup>Food safety Research group, Korea Food Research Institute, Seongnam-si Gyeonggi-do, Korea

**Background**

The discovery of new agent is demanded by the appearance of multidrug resistant bacteria, like super bacteria, for many years. Also, quorum sensing, cell-to-cell communication, is regarded as remarkable target for development of new antibiotics in recent

**Objectives**

In this study, we investigated antibacterial and anti-quorum sensing (anti-QS) capacity of dietary plants cultivated in Korea and their effect on formation of bacterial biofilms.

**Methods**

Inhibition of quorum sensing (QS) was investigated using the biosensor bacteria *Chromobacterium violaceum* and *Pseudomonas aeruginosa* PA01. The crude extracts of five plants were evaluated on antibacterial activity against five major food pathogen by bi-layer agar well method.

**Conclusions**

Especially, the extract of *Zingiberaceae* plant inhibited production of violet pigment in *C. violaceum* at 10mg/ml and the extracts of *Punica granatum* L. and *Prunella mume* showed anti-QS activity against *C. violaceum*. Biofilm formation was measured by crystal violet and resazurin staining and the extract from *Zingiberaceae* plant had lower minimal inhibitory concentration than that of *Citrus junos* and *Punica granatum* L. All of the extracts showed antibacterial activity against *S. aureus*, *L. monocytogenes*, and *B. cereus*. The extract of *Punica granatum* L. also had high activity against *E. coli* and *S. Enteritidis*. The extract from *Zingiberaceae* plant had lower minimal inhibitory concentration (MIC) than that of *Punica granatum* L. against gram positive bacteria. The extract of *Zingiberaceae* plant had the lowest MIC of 50ug/ml against *S. aureus* and *L. monocytogenes*. These results exhibit the potential of five dietary plants to use as food preservatives and new antibacterial agents.

## **Background**

The regulation of biofilm-formation in many pseudomonads is controlled by quorum sensing (QS) and is key to their ability to colonize different environments. However, in the soil and plant-associated *P. fluorescens* SBW25, mutations in diguanylate cyclase-associated genes increase c-di-GMP levels to induce attachment and cellulose expression, resulting in the formation of biofilms at the air-liquid interface of static microcosms, and no involvement of QS-dependent behaviour has been reported.

## **Objectives**

The objective of the study was to examine the ability of SBW25 to quorum sensing.

## **Methods**

Bioinformatics, cultivation assays, TLC and CLSM were used.

## Conclusions

A bioinformatics analysis of the SBW25 genome has identified putative N-acyl homoserine lactone (AHL) and  $\alpha$ -hydroxy ketone (AHK)-dependent QS pathways, including an AHL/AHK synthase-like protein belonging to the HdtS family (PFLU0050) and a CqsA-like protein (PFLU5614). Furthermore, a putative link can be established between QS and the regulation of c-di-GMP levels in SBW25 based on the TpbA/TpbB system of *P. aeruginosa*. In this preliminary work, bioassays with AHL/AHK reporter strains overlaid onto TLC of liquid culture extracts demonstrate that SBW25 produces detectable levels of AHL and AHKs. Although these quorum compounds have yet to be identified, tests using exogenous dodecanoyl homoserine lactone suggest that in SBW25, biofilm structure, eDNA, and possibly siderophore production, may all be regulated by QS pathways. This work is the first to provide experimental proof that SBW25 is capable of responding to AHL/AHK quorum signals like many other pseudomonads, and to suggest that biofilm-formation may also be AHL-regulated under different environmental conditions.

**CELL-CELL COMMUNICATION PROVIDES FITNESS BENEFITS TO POPULATIONS OF LISTERIA MONOCYTOGENES IN THE SOIL ENVIRONMENT**

*D. Garmyn*<sup>1</sup>, *A.L. Vivant*<sup>1</sup>, *L. Gal*<sup>1</sup>, *P. Piveteau*<sup>1</sup>

<sup>1</sup>*Agroécologie, UMR Agroécologie 1347, Dijon, France*

**Background**

*Listeria monocytogenes* is a ubiquitous opportunistic human pathogen detected in many habitats spanning from the farm environment to food industry and the gastrointestinal tract.

Cell-cell communication participates to the adaptation of bacteria to their environment. In the species *Listeria monocytogenes*, the Agr system is required for full virulence and biofilm formation but its actual role is still poorly understood.

**Objectives**

To investigate whether the ability to communicate provides a benefit to *L. monocytogenes* in soil, a complex environment combining biotic and abiotic characteristics.

**Methods**

Deletion of the gene coding the response regulator or the signal propeptide. Population dynamics of the mutant and/or parental strains in soil microcosms. Both unsterilised and sterilised soils were investigated.

**Conclusions**

Deletion of the gene coding the regulator or the signal did not affect population dynamics in sterilized soil but survival was altered in biotic soil suggesting that the Agr system was involved to face the complex soil biotic environment. This was confirmed by co-incubation experiments. The fitness of the response negative mutant was lower either in the presence or absence of the parental strain but the fitness of the signal negative mutant depended on the strain with which it was coincubated. Survival of the signal negative mutant was higher when cocultured with the parental strain than when cocultured with the response negative mutant. These results showed that the ability to respond to communication provided a benefit to listerial cells. These results might also indicate that in soil, the Agr system controls private goods rather than public goods.

*<sup>2</sup>Institute of Plant Biology and Biotechnology – Laboratory of Molecular Phytopathology and Renewable Resources, Muenster, Germany*

**Background**

The quorum sensing (QS) hypothesis explains a type of bacterial cell-cell communication which is mediated by means of autoinducer low molecular weight exocellular compounds. This phenomenon has profound implications in the control of many important bacterial traits (e.g. biofilm formation, secretion of virulence factors, etc.). A typical QS system in gram-negative bacterial involves the production and response to acylated homoserine lactone (AHL) signals that are recognized by the LuxR receptor. Several strategies have been conceived to block or disrupt QS (known as quorum quenching, QQ) and thus offer an alternative strategy to reduce the collective power of bacterial pathogens.

**Objectives**

In this regards, we have screened a library of total 24 purified compounds and have tested their QQ activity when applied at a concentration of 1mM.

**Methods**

To this end an *E. coli* Top 10 biosensor reporter of AHL-mediated QS which constitutively expresses green fluorescent protein (GFP) upon exogenous addition of 3-oxo-hexanoyl homoserine lactone (3OC<sub>6</sub>HSL) has been used. A computer-based docking approach was used to elucidate in further detail the interaction between the hit compounds with the TraR protein 3D crystal structure.

**Conclusions**

The hit compounds (i.e. able to inhibit significantly the production of GFP but without inducing a toxic response) were vanillin, trans-cinnamaldehyde, caffeine, genipin, PQS (Pseudomonas quinolone signal) and MOQ (1H-2-methyl-4-quinolone). We have also tested the effect of loading the hit compounds into chitosan-based nanocapsules on their QQ activity and found that this is a strategy to further control and modulate their QQ bioactivity.

<sup>2</sup>Core Unit Systems Medicine, University of Würzburg, Würzburg, Germany

<sup>3</sup>Institut für Molekulare Infektionsbiologie, University of Würzburg, Würzburg, Germany

<sup>4</sup>Plant Genetics Research Unit Agricultural Research Service, United States Department of Agriculture, Columbia, USA

### Background

The alphaproteobacterium *Sinorhizobium fredii* NGR234 is outstanding and unique among the rhizobia with its ability to form nitrogen-fixing nodules with a wide range of legumes (1). Beside many other striking features, its 6.9 Mbp genome encodes for two *N*-acyl-homoserine-lactone synthase genes (i.e. *tral* and *ngrl*) which are involved in the biosynthesis of two distinct autoinducer I-type molecules (2,3).

### Objectives

Here we report on the construction of a NGR234- $\Delta$ *tral* and a NGR234- $\Delta$ *ngrl* mutant and their genome wide transcriptome analysis. The high-resolution RNA-seq analysis of early stationary phase cultures in the NGR234- $\Delta$ *tral* background suggested that up to 316 genes were differentially expressed in the NGR234- $\Delta$ *tral* mutant vs. the parent strain and 466 in the background of NGR234- $\Delta$ *ngrl* vs. the parent strain. Accordingly, a common set of 186 genes was regulated by the Tral/R and Ngrl/R regulon including flagella biosynthesis genes and genes linked to EPS succinoglycan biosynthesis. Among the genes that were differentially regulated in NGR234- $\Delta$ *tral* were those linked to replication of the pNGR234a symbiotic plasmid and cytochrome c oxidases. In the NGR234- $\Delta$ *ngrl* mutant biotin and pyrroloquinoline quinone biosynthesis genes were differentially expressed as well as the entire cluster of the NGR234 type III secretion system (T3SS-II). Further we also discovered that genes responsible for rhizopine catabolism in NGR234 were strongly repressed in the presence of high levels of *N*-acyl-homoserine-lactones.

### Methods

high-resolution RNA-seq analysis

### Conclusions

Together with nodulation assays, our RNA-seq-based findings suggested that QS-dependent gene regulation appears to be of higher relevance during non-symbiotic growth rather than for life within root nodules.

**REGULATORY RNA ARISES FROM 3'-UTR OF AHL SENSOR ENCODED RNA AFTER ITS PREPROCESSING IN PECTOBACTERIUM ATROSEPTICUM**

L.V. Shlykova<sup>1</sup>, N.E. Gogoleva<sup>1</sup>, V.Y. Gorshkov<sup>1</sup>, Y.V. Gogolev<sup>1</sup>

<sup>1</sup>The Laboratory of Molecular Biology,

Kazan Institute of Biochemistry and Biophysics Kazan Scientific Center of the Russian Academy of Sciences, Kazan, Russia

**Background**

In a broad group of proteobacteria two quorum sensing-related genes, which encode synthase of autoinducers and their sensor, respectively, have convergent topology and overlap by their 3'-ends. It was suggested that the expression of one gene may antagonize the transcription of another one because of the convergent arrangement of these genes.

**Objectives**

We proposed that the topology of quorum sensing-related genes of plant pathogenic bacterium *Pectobacterium atrosepticum*, *expI* and *expR*, determines the mechanism of regulation of their expression.

**Methods**

We noticed that *expR* gene lacks any obvious transcriptional stop signals. Using chain-specific RT-qPCR we found that at the stationary growth phase *expR* mRNAs having long 3'-untranslated region (UTR) were formed and the expression of oppositely oriented *expI* gene was simultaneously decreased. It is likely, that RNA products of the *expR* regulatory gene may inhibit the expression of the autoinducer synthase gene through the interactions with *expI* mRNA. Using 3'-RACE method we found that at the stationary growth phase the extended *expR* transcripts underwent preprocessing resulting in their break down into two fragments. The first fragment encompassed the entire length of open reading frame (ORF) of *expR* gene and the second one included only a long 3'-UTR having a predicted regulatory function.

**Conclusions**

We found that *cis*-encoded RNA may participate in the regulation of expression of two convergent functionally related genes. The length of one of two transcripts varies respective to the cell growth phase affecting the expression of oppositely oriented gene. Moreover, *cis*-encoded regulatory RNAs arises from protein encoded RNAs that undergo preprocessing in their 3'-UTR.

## PROTEOME PROFILING OF BURKHOLDERIA PSEUDOMALLEI QUORUM SENSING MUTANTS

K. Stoll-Ziegler<sup>1</sup>, C. Kohler<sup>2</sup>, D. Zühlke<sup>1</sup>, I. Steinmetz<sup>2</sup>, K. Riedel<sup>1</sup>

<sup>1</sup>University Greifswald, Institute for Microbiology, Greifswald, Germany

<sup>2</sup>University Medicine Greifswald, Friedrich-Loeffler-Institute for Medical Microbiology, Greifswald, Germany

### Background

*Burkholderia pseudomallei*, the causative agent of melioidosis, is a gram-negative soil bacterium in tropical areas. *B. pseudomallei* employs several *N*-acyl-homoserine lactone (AHL)-mediated quorum sensing (QS) systems, which activate specific sets of genes as a function of cell density [1]. The genome of *B. pseudomallei* encodes genes for three QS systems with one *luxI* and one *luxR* homologue, respectively, and additionally three orphan *luxR* homologues [2]. The *luxI* homologues encode AHL synthases, which produce specific AHLs binding to the respective transcriptional regulator and thus regulating expression of specific genes involved in virulence like biofilm formation, siderophore biosynthesis or swarming motility [3].

### Objectives

The aim was to clarify the influence of the different QS systems on virulence factor expression.

### Methods

We constructed mutants in the synthase-coding genes. Subproteome fractions of the mutant strains were subjected to mass spectrometry analysis to identify targets of the different QS systems. We used the DIA approach IMS<sup>E</sup> in combination with the Hi3 approach for quantification of cytosolic proteins and the GeLC MS/MS approach for the analysis of extracellular proteins. Furthermore, the AHL spectrum, synthesized by the different QS systems was determined by analytical thin layer chromatography.

### Conclusions

The *luxI* homologues influence protein expression by up- and downregulation of AHL-dependent proteins in the QS circuitry of *B. pseudomallei*.

## **ENZYMATIC PRODUCTION OF MODIFIED STARCHES WITH SLOW DIGESTION PROPERTIES**

N. Yoon<sup>1</sup>, J. Park<sup>1</sup>, J. Moon<sup>1</sup>, M. Park<sup>1</sup>, J. Cha<sup>1</sup>

<sup>1</sup>Microbiology, Pusan National University, Busan, Korea

### **Background**

In human nutrition, the proper rate of glucose release and absorption from digesting starch may play important roles in body health. Therefore, improving food quality with higher amounts of slow digestible starch is becoming an area of interest for researchers in academia and industry.

### **Objectives**

The objectives of this study is to produce the modified starch with slow digestion properties by starch-modifying enzymes.

### **Methods**

Two branching enzymes (BEs), PH1386 of *Pyrococcus horikoshii* OT3 and Athe\_0558 of *Caldicellulosiruptor bescii*, were expressed in *E. coli* and purified by Ni-NTA affinity chromatography. The enzymatic properties of two BEs have been studied by high performance anionic exchange chromatography (HPAEC) analysis. The melting temperature range (Tr) and melting enthalpy ( $\Delta H$ ) representing the degree of retrogradation of modified starches were also studied by differential scanning calorimetry. Finally, the digestion properties of modified starches were examined by pancreatic enzyme and  $\alpha$ -glucosidase.

### **Conclusions**

HPAEC analysis of BE-modified starches revealed that PH1386 produces the branch chains with mainly DP 10-12, while Athe\_0558 prefers DP 6-7. The proportion of A chains (DP  $\leq 12$ ) of amylopectin was increased and the proportion of B1 (DP 13-36) and B2 chains (DP  $\geq 37$ ) was decreased compared to control. The Tr and  $\Delta H$  also decreased compared to control, suggesting that retrogradation rate of the BE-modified starches was delayed. The increased resistant starch contents and

decreased rapidly digestible starch contents of BE-modified starches are thought to be due to the increase in  $\alpha$ -1,6 linkages and the highly branched structure of starch.

**MAXIMIZING BIOTECHNOLOGICAL PRODUCTION OF 3-HYDROXYPROPIONALDEHYDE AS A NATURAL FOOD PRESERVATIVE WHILE MINIMIZING ITS CONVERSION TO TOXIC ACROLEIN**

C. Engels<sup>1</sup>, C. Schwab<sup>1</sup>, M.J.A. Stevens<sup>1</sup>, S.J. Sturla<sup>1</sup>, C. Lacroix<sup>1</sup>

<sup>1</sup>Health Sciences and Technology, Swiss Federal Institute of Technology, Zurich, Switzerland

**Background**

3-hydroxypropionaldehyde (3-HPA) has strong antimicrobial activity and application potential as a natural food preservative for disinfection of minimally processed vegetables. During glycerol metabolism, *Lactobacillus reuteri* DSM 20016T can accumulate 3-HPA, which undergoes reversible dimerization and hydration, and can be further converted enzymatically into inactive 1,3-propanediol (1,3-PD), restoring intracellular redox potential. Dehydration of 3-HPA resulting in acrolein, a toxic metabolite, is also possible, however, conditions promoting this transformation have not been fully understood due to the lack of analytical methods to simultaneously quantify 3-HPA as well as acrolein.

**Objectives**

The aim of this study was to maximize the capacity for biotechnological processing of glycerol to 3-HPA using *L. reuteri*, while accounting for the accumulation of acrolein after production and storage to evaluate toxicological risk.

**Methods**

Strategies to improve 3-HPA production included the addition of redox-active compounds during glycerol fermentation to prevent conversion to 1,3-PD, the usage of immobilized cells resulting in high densities of viable cells as well as the optimization of process parameters in batch and fed-batch processes. Special attention was paid to cultivation conditions of *L. reuteri* prior to glycerol conversion. Acrolein and 3-HPA were simultaneously quantified using a newly established analytical method employing ion-chromatography with pulsed amperometric detection.

**Conclusions**

Redox-active compounds, process conditions and pre-treatment of *L. reuteri* cultures influenced 3-HPA yield as well as ratio of 3-HPA to 1,3-PD. Temperature and pH

optimization prevented formation of acrolein during biotechnological production and storage, promoting the safety of 3-HPA when applied as natural food preservative.

**COMPARATIVE STUDY OF FERMENTATION PROCESSES BY FREE AND IMMOBILIZED GRAPEVINE INDIGENOUS STRAINS FOR THE PRODUCTION OF HIGH QUALITY WINES**

M. Filippou<sup>1</sup>, E. Karabika<sup>2</sup>, Troianou E.<sup>1</sup>, M. Parapouli<sup>1</sup>, P.-Y. Stergiou<sup>2</sup>, A. Foukis<sup>2</sup>, D. Noutsopoulos<sup>1</sup>, A. Afendra<sup>1</sup>, E.M. Papamichael<sup>2</sup>, E. Hatziloukas<sup>1</sup>

<sup>1</sup>Department of Biological Applications and Technology, University of Ioannina, Ioannina, Greece

<sup>2</sup>Chemistry Department, University of Ioannina, Ioannina, Greece

**Background**

Vinification is a complex microbiological process. Immobilized microorganisms constitute an alternative approach aiming to lower the overall cost of production and improve wine quality.

**Objectives**

This study focuses on the immobilization of indigenous *Saccharomyces* and non-*Saccharomyces* strains for use in wine production.

**Methods**

*Saccharomyces cerevisiae* strains are known for their ability to produce high ethanol levels, while non-*Saccharomyces* species contribute to the enhancement of the wine flavor resulting in high quality wines. Two indigenous environmental yeast strains isolated from a Greek agricultural region (Zitsa, Epirus), *Saccharomyces cerevisiae* Z622 and *Metschnikowia pulcherrima* var Zitsae ZY6 were used as starter cultures in a sequential fashion for wine fermentation. Delignified cellulose is used as an immobilization support meeting all requirements and demands for use in food production and wine making.

**Conclusions**

Both yeast strains were successfully immobilized maintaining their metabolic activity during fermentation. Immobilized cells showed a better overall metabolic activity compared to control free cells.

**LACTOBACILLUS SAKEI ISOLATED FROM FERMENTED MEAT: EXTERNAL ANTIBACTERIAL ACTIVITY AGAINST LACTIC ACID BACTERIA AND PATHOGENIC STRAINS**

*I. García-Cano*<sup>1</sup>, *E. Ponce-Alquicira*<sup>1</sup>

<sup>1</sup>*Biología, Universidad Autónoma Metropolitana Unidad Iztapalapa, Mexico City, Mexico*

**Background**

Lactobacilli play an important role in the production of fermented sausages, due to their antimicrobial activity and their effect on the organoleptic properties of meat products. *Lb. sakei* is gaining relevance because it produces bacteriocins with anti-listerial activity. However, the use of bacteriocins may be limited due to their action against phylogenetically related species and ineffectiveness against some pathogenic and undesirable spoilage bacteria. Another group of proteins with antibacterial activity are peptidoglycan hydrolases, which so far have not been reported for this bacterial species and probably play a role in food safety and in the organoleptic properties of meat products; because they prevent the growth of pathogens and spoilage bacteria, including heterofermentative lactic acid bacteria (LAB).

**Objectives**

The aims of this work were to identify lactic acid bacteria isolated from fermented meat, as well as the proteins responsible for their extracellular antibacterial activity against different pathogenic and LAB strains

**Methods**

Isolated lactobacilli were identified by 16S rDNA sequencing. Antimicrobial and lytic activities were evaluated in the culture supernatant by agar diffusion tests and zymography, using in both cases different target microorganisms. A 79-kDa protein was identified which showed antimicrobial activity. Protein identification was performed by LC/MALDI TOF/TOF and the data showed a high correspondence with a putative N-acetylmuramoyl-L-alanine amidase.

**Conclusions**

A *Lb. sakei* strain isolated from fermented meat which has displayed external antibacterial activity has been cultured and studied for the first time. The aforesaid activity is probably related to an protein with peptidoglycan hydrolase activity. This may have a potential use in food preservation, considering that this activity was obtained from a bacteria isolated from a meat product.

**LEVANSUCRASE OF PSEUDOMONAS SYRINGAE AS PRODUCER OF NOVEL PREBIOTIC FRUCTANS: A STRUCTURE-FUNCTION STUDY OF THE ENZYME**

M. Gromkova<sup>1</sup>, K. Mardo<sup>1</sup>, T. Visnapuu<sup>1</sup>, T. Alamäe<sup>1</sup>

<sup>1</sup>Genetics, Institute of Molecular and Cell Biology University of Tartu, Tartu, Estonia

**Background**

Gut microbiota has numerous roles in human life and its significance has thus far been underestimated. Therefore, more detailed studies on diversity and metabolism of gut microbiota are needed.

**Objectives**

Gut microbiota can be shaped by prebiotics. Levan-type ( $\beta$  2,6-linked) fructans can be considered as potential prebiotics<sup>[1]</sup>. We have synthesized levan and levan-type fructooligosaccharides by heterologously expressed levansucrase Lsc3 of *Pseudomonas syringae* pv. tomato. These substrates should affect gut microbiota as were perfectly fermented by a gut generalist *B. thetaiotaomicron*<sup>[2]</sup>. Here we focus on structure-function relationships of the Lsc3 protein and its biotechnological potential.

**Methods**

The His-tagged Lsc3 protein was site-directedly mutated, biochemical methods were used to characterize the mutant proteins and 3D structure modelling was applied to interpret the results.

**Conclusions**

Levansucrase Lsc3 has high polymerizing activity (up to 80%) and extremely high stability confirming its biotechnological potential for the synthesis of fructans. Several novel catalysis-related positions for levansucrases were revealed and their predicted location on a 3D model of Lsc3 will be presented.

<sup>2</sup>Kluyver Centre, NIZO food research, Ede, Netherlands

<sup>3</sup>CMBI, NIZO food research, Ede, Netherlands

<sup>4</sup>TIFN, NIZO food research, Ede, Netherlands

**Background**

*Lactococcus lactis* is industrially employed to manufacture fermented dairy products. Spray drying is the cheapest preservation method for *L. lactis* starter cultures, but during this process cultures encounter heat and oxidative stress, resulting in low survival. Viability of starter cultures is essential for their role in dairy acidification, supporting the need to understand and improve their robustness.

**Objectives**

We have measured the ability of 39 *L. lactis* strains to survive industrially relevant stresses. This set of strains contained different *L. lactis* strains from dairy as well as plant origin. The observed 4-log variation in heat and oxidative stress survival was compared with genomic content, resulting in the identification of genes associated with robustness. Presence and activity of genes can play an important role in the observed diversity in robustness.

**Methods**

Therefore, four *L. lactis* strains with varying robustness phenotypes were fermented under twelve different conditions, varying in temperature, salt concentration, pH, and oxygen level. Cells were harvested at exponential phase of growth for transcriptome analysis and survival measurements.

**Conclusions**

The varying growth conditions resulted in up to 4-log differences in robustness towards heat and oxidative stress. Moreover, clear differences in gene expression profiles were observed. Correlation of robustness phenotypes and gene expression levels revealed transcriptome signatures for oxidative and heat stress survival. For strain MG1363 this included the *metC-cysK* operon, involved in methionine and cysteine metabolism, which triggered us to grow this strain in the absence of

cysteine, resulting in elevated expression levels of the *metC-cysK* operon and concomitant enhanced robustness towards oxidative stress.

## **IMPROVEMENT OF SECRETORY EXPRESSION FOR THE SWEET-TASTING PROTEIN BRAZZEIN IN YEAST**

K. Kong<sup>1</sup>, M. Kim<sup>1</sup>, J. Lim<sup>1</sup>

<sup>1</sup>Chemistry, Chung-Ang University, Seoul, Korea

### **Background**

Brazzein is an intensely sweet-tasting protein with four disulfide bridges. In previous study, we constructed the secretory expression system of recombinant brazzein in yeast *Kluyveromyces lactis*.

### **Objectives**

In this expression system, the control of protein disulfide-bond formation in the endoplasmic reticulum (ER) is often a bottleneck for secretory protein production. The major pathway for protein disulfide-bond formation in endoplasmic reticulum (ER) includes the conserved ER-membrane protein Ero1p and protein disulfide isomerase (PDI).

### **Methods**

In the present study, the PDI gene was introduced in the yeast *Kluyveromyces lactis* to improve the secretory efficiency of brazzein. The expression of Ero1p was also induced by treatment of the cells with dithiothreitol. The culture condition of the yeast transformants for high yield secretion of the recombinant des-pE1M-brazzein was in YPGal medium for 96 hours at 30 °C.

### **Conclusions**

The amount of misfolded or unfold recombinant des-pE1M-brazzein remaining inside the cell decreased and the amount of the secretory recombinant des-pE1M-brazzein having an intrinsic sweetness increased approximately 1.7-fold than that of the previous expression system. These results demonstrate that the modified *K. lactis* expression system could be applicable to mass production of the recombinant brazzein with attributes useful in the food industry.

**Food biotechnology**

**IDENTIFICATION OF SULPHITE RESISTANCE WINE YEASTS  
SACCHAROMYCES CEREVISIAE FROM A POOL OF SELECTED STRAINS**

A. Misiewicz<sup>1</sup>, K. Kaminska-Wojteczek<sup>1</sup>, A. Goncerzewicz<sup>1</sup>

<sup>1</sup>Department of Microbiology,

Waclaw Dabrowski Institute of Agricultural and Food Biotechnology, Warsaw, Poland

**Background**

Sulphite is frequently added in winemaking, hence sulphite resistance mechanisms have been studied extensively in *Saccharomyces cerevisiae*. Research turned out that yeasts possess plasma membrane protein encoded by the *SSU1* gene (lies on chromosome XVI), which excretes sulphite from yeast cells. Some highly sulphite-resistance wine strains have an *SSU1* allele – *SSU1-R* - on chromosome VIII. We tried to elucidate, how long adaptation to high sulphite concentrations affects to the evolution of yeast strains.

**Objectives**

The aim of experiment was to determine presence of *SSU1* and *SSU1-R* genes and their expression in selected *Saccharomyces cerevisiae* strains.

**Methods**

After 10 years of storage with SO<sub>2</sub> (concentration ~ 400 mg/ml) the pool of 12 strains *S. cerevisiae*, include 11 sulphite strains and negative control strain, were tested for the presence of the *SSU1* or *SSU1-R* gene. We analysed them by using PCR assays, gel electrophoresis and DNA sequencing. Obtained sequences were aligned, in CLUSTAL W tool, with known sequences from databases (BLAST and SGD). Gene expression was tested during alcoholic fermentation for few strains by real-time PCR.

**Conclusions**

The presence of the *SSU1* gene was confirmed in 7 strains (include control strain) and *SSU1-R* gene in 3 strains. None of those genes was detected in 2 strains. The results indicate that possession of the *SSU1* or its allele is independent of the long term storage in must with SO<sub>2</sub>. It is well-known that evolution in yeast cells occur dynamic. In our research it was confirmed by the presence of *SSU1* in negative control strain.

**Food biotechnology**

## **INFLUENCES OF DIFFERENT MINERALS ON THE GROWTH AND CITRIC ACID PRODUCTION OF *YARROWIA LIPOLYTICA***

S. Karasu-Yalcin<sup>1</sup>, M.T. Bozdemir<sup>2</sup>, Z.Y. Ozbas<sup>3</sup>

<sup>1</sup>Food Engineering Department, Abant Izzet Baysal University, Bolu, Turkey

<sup>2</sup>Chemical Engineering Department, Hacettepe University, Ankara, Turkey

<sup>3</sup>Food Engineering Department, Hacettepe University, Ankara, Turkey

### **Background:**

Citric acid is the most important and widely used organic acid produced by fermentation. Mineral composition of the fermentation medium has a critical role in citric acid production.

### **Objectives:**

The aim of this study was to investigate the influences of different minerals on growth and citric acid production of *Yarrowia lipolytica* NBRC 1658 in a glucose medium.

### **Methods:**

The mineral salts; FeSO<sub>4</sub>, CuSO<sub>4</sub>, MnSO<sub>4</sub> and ZnSO<sub>4</sub> were added to the fermentation medium separately with concentration ranges of 0.01-0.1, 0.001-0.02, 0.005-0.05 and 0.002-0.008 g/L, respectively. Experiments were performed in a batch system. Biomass concentration was determined spectrophotometrically. Concentration of citric acid was measured by pyridine-acetic anhydride method.

### **Conclusions:**

In this study it was obtained that by the addition of FeSO<sub>4</sub> into the media, the specific growth rate of the yeast increased and although CuSO<sub>4</sub> addition had a positive effect on the decrease of the duration of the lag phase, it had an adverse effect on the citric acid production as well. The maximum specific growth rate of the yeast determined as 0.053 h<sup>-1</sup> by using 0.02 g/L of MnSO<sub>4</sub> in the glucose based medium. Although ZnSO<sub>4</sub> supported the growth of the yeast, citric acid concentration reduced and reached to a maximum value of 13.4 g/L. It was also concluded that citric acid production decreased by the supplement of the salts examined within the concentration ranges above, while certain concentrations of FeSO<sub>4</sub>, MnSO<sub>4</sub> and ZnSO<sub>4</sub> had profound effects on the growth of the yeast.

## **ENHANCEMENT OF THE BIOAVAILABILITY OF EXTRACTABLE BERRY PHENOLICS BY SOLID STATE FERMENTATION**

M. Takó<sup>1</sup>, A. Kotogán<sup>1</sup>, G. Babos<sup>1</sup>, A. Sója<sup>1</sup>, T. Papp<sup>1</sup>, C. Vágvolgyi<sup>1</sup>, J. Krisch<sup>2</sup>

<sup>1</sup>Department of Microbiology, University of Szeged, Szeged, Hungary

<sup>2</sup>Institute of Food Engineering, University of Szeged, Szeged, Hungary

### **Background**

Increasing interest can now be observed for the utilization of plant-wastes rich in extractable phenols derived from fruit processing. Using these residues, free phenolics with high antioxidant potential can be liberated by solid-state fermentation, via the deglycosylation action of beta-glucosidases of the fermenting fungi. Thus, the bioavailability of the extractable phenols can be enhanced since aglycons get across the cell membrane easily.

### **Objectives**

In our previous studies, isolates of *Rhizomucor miehei* and *Mucor corticolus* showed intensive extracellular beta-glucosidase activity on plant-derived residues. Here, we analyzed the ability of these zygomycetes to generate free phenolics under jostaberry-based solid-state fermentation.

### **Methods**

Solid pomace medium was supplemented with soy flour as nitrogen source. During incubation samples were taken every second or third day and extracted with distilled water, ethanol:water 50:50 or HCl:methanol 10:90 solutions. Besides beta-glucosidase activity, total phenolics and total anthocyanins were determined. Antioxidant activity tests including radical scavenging capacity and ferric reducing capacity assays were also performed.

### **Conclusions**

The *R. miehei* and *M. corticolus* bioconversion of jostaberry pomace leads to enhanced total phenolic content. Positive correlation between total phenolic content and beta-glucosidase activity was found in both systems. Ferric reducing antioxidant power was slightly increased during the first phase of fermentation; however, anthocyanin content showed significant drop after 3-5 days. Results indicate that *R. miehei* and *M. corticolus* fermentations are applicable methods for liberation and enrichment of health-relevant extractable phenolics from jostaberry pomace. This research was supported by the Hungarian Research Fund (OTKA PD 112234).

**INFLUENCE OF STARTER INOCULUM ON DYNAMIC GROWTH OF  
STREPTOVERTICILLIUM MOBARAENSE IN O3 MEDIUM.**

D. Pietracha<sup>1</sup>, K. Szewczuk<sup>1</sup>, F. Zdziennicki<sup>1</sup>, A. Misiewicz<sup>1</sup>

<sup>1</sup>Department of Microbiology,

Waclaw Dabrowski Institute of Agricultural and Food Biotechnology, Warsaw, Poland

**Background**

*Streptoverticillium mobareense* KKP 2013 strain obtained from the Culture Collection of Industrial Microorganisms is Gram-positive *Actinomyces* commonly occurring in natural environment. Under certain conditions, it has the ability to produce the enzyme MTG, protein-glutamine gamma-glutamyltransferase, EC 2.32.13, commonly called transglutaminase. Transglutaminase catalyzes the formation of a covalent bond between the proteins, it allows also crosslinking reactions, namely the production of new intra- or intermolecular bonds between the proteins and peptides. MTG due to its characteristics is widely used in the production of meats, dairy and bakery products.

**Objectives**

In the process for producing transglutaminase one of the important steps is to obtain an appropriate number of microorganisms, which allows to obtain the highest possible quantity of active enzyme.

**Methods**

In our study, we tried to determine the growth rate of strain KKP 2013 *S. mobaraense* in the proliferating medium O3. In the precise number of microorganisms on the breeding stage, we used the method of pour plate technique on PCA medium, according to PN-EN ISO 4833-1: 2013-2014.

**Conclusions**

We established the optimal volume of medium in relation to the number of bacteria in the starting inoculum, which will produce the highest activity of the resulting enzyme.

**USING DYNAMIC SINGLE CELL BIOLOGY TO DISSECT INJURY,  
RESUSCITATION AND DEATH PHENOMENA IN STRESSED POPULATIONS OF  
ESCHERICHIA COLI**

S. Govers<sup>1</sup>, A. Ghosh<sup>1</sup>, A. Cambré<sup>1</sup>, E. Gayan<sup>1</sup>, A. Aertsen<sup>1</sup>

<sup>1</sup>*Microbial and Molecular Systems, KU Leuven, Leuven, Belgium*

**Background**

While inimical food preservation approaches often result in heavily damaged and stressed populations of foodborne pathogens and spoilage microorganisms, very little is known about the actual molecular and genetic events and dynamics that govern the (sub)lethal injury and subsequent resuscitation or death of these cells. Nevertheless, insights into these phenomena might be decisive for a proper understanding of the resulting behavior and evolvability of the surviving subpopulation.

**Objectives**

In this study, we set out to monitor and dissect (sub)lethal injury and resuscitation phenomena in populations and cells of *Escherichia coli* that are stressed by heat or high hydrostatic pressure treatment.

**Methods**

Directed evolution, genetics and time-lapse fluorescence microscopy.

**Conclusions**

Based on adaptive mutations, genetics and live cell biology, different subcellular processes and structures have been delineated and monitored that play a role in the heterogeneous injury and resuscitation dynamics of high temperature or pressure stressed *E. coli* cells and populations, thereby revealing a surprising impact on the spatial dynamics of nucleoids and protein aggregation inside stressed cells.

**INHIBITION OF *S. AUREUS* A, B, C AND D ENTEROTOXINS BY SUBINHIBITORY DOSES OF TERPENOID PHENOLS FROM PLANTS ESSENTIAL OILS**

M. Albano<sup>1</sup>, F.C.B. Alves<sup>1</sup>, L.N. Barbosa<sup>1</sup>, B.F.M.T. Andrade<sup>1</sup>, V.L.M. Rall<sup>1</sup>,  
A. Fernandes Júnior<sup>1</sup>

<sup>1</sup>Microbiology and Immunology,

São Paulo State University "Júlio de Mesquita Filho"/UNESP, Botucatu/SP, Brazil

**Background**

*Staphylococcus aureus* is a pathogen of major concern for clinical infection and foodborne illness and has remarkable invasiveness and toxin-mediated virulence. Studies have shown that plant essential oils can influence production of toxins, avoiding overuse of antibiotics and the development of bacterial resistance.

**Objectives**

This study aimed to verify the influence of major terpenoid phenols compounds from plants essential oils in subinhibitory doses on enterotoxins A, B, C and D produced by *Staphylococcus aureus*.

**Methods**

Five phenolic compounds (eugenol, geraniol, cinnamaldehyde, citronellol and terpineol) were tested. Amounts corresponding to 60% and 80% of Minimum Inhibitory Concentration (MIC<sub>90%</sub>) were added to culture medium Tryptic Soy Broth (TSB). Each treatment was inoculated with a suspension of *S. aureus* producer of each enterotoxin A, B, C and D and incubated (37°C/24h). TSB without compounds was used as positive control. After incubation each treatment was centrifuged (9000g/4°C/30min) and supernatant was used to detect enterotoxin production by Reverse Passive Latex Agglutination. Interpretation of results was performed according to manufacturer's instructions kit. Agglutination was characterized as: strong (+++); moderate (++); weak (+) and absence (-) of enterotoxin production. Assays were performed in duplicate. Kruskal-Wallis nonparametric test was performed using scores related to enterotoxin production.

**Conclusions**

Some phenolic compounds from plants essential oils tested demonstrated great capacity to inhibit enterotoxins produced by *S. aureus* and, consequently decreasing its virulence. Therefore, it may be a promising way to prevent diseases caused by enterotoxigenic *S. aureus* and to contribute for reduction of antimicrobial drugs consumption.

## **CHARACTERIZATION OF THE DAIRY STREPTOCOCCUS THERMOPHILUS ACA-DC 29 STRAIN THROUGH COMPARATIVE GENOMICS**

V. Alexandraki<sup>1</sup>, M. Kazou<sup>1</sup>, P. Renault<sup>2</sup>, B. Pot<sup>3</sup>, E. Tsakalidou<sup>1</sup>, K. Papadimitriou<sup>1</sup>

<sup>1</sup>Food Science and Human Nutrition, Agricultural University of Athens, Athens, Greece

<sup>2</sup>Micalis, INRA, Lille, France

<sup>3</sup>Center for Infection and Immunity of Lille, Institut Pasteur de Lille, Lille, France

### **Background**

Although the *Streptococcus* genus includes mainly pathogenic species, *Streptococcus thermophilus* is a widely used dairy starter culture of great economic importance for the food industry. *S. thermophilus* has been adapted to milk probably through a degenerative evolution process that has led to the loss of typical streptococcal pathogenic traits.

### **Objectives**

The genome sequence of the yogurt isolate *S. thermophilus* ACA-DC 29 was analyzed for assessing the technological potential of this strain. Comparative genomics analysis was also performed between the genome of ACA-DC 29 and the existing complete genome sequences of *S. thermophilus*.

### **Methods**

The genome sequence of ACA-DC 29 was annotated using online annotation tools. Full chromosome alignments were calculated with Progressive Mauve. The pangenome, the core genome and the unique genes were predicted with the GView Server. The genomic islands, the CRISPRs and the antimicrobial peptides were predicted with IslandViewer, CRISPRcompar and BAGEL3, respectively.

### **Conclusions**

The analysis of the *S. thermophilus* ACA-DC 29 genome sequence revealed the absence of pathogenic features. Genes related to the adaptation to milk were identified. Full chromosome alignments showed a high degree of synteny among the different strains. The pangenome of the eight strains comprised of approximately 2,300 genes. Concerning the ACA-DC 29 strain, approximately 250 unique genes involved in various biological processes were also identified. Further analysis indicated that several of them may have been acquired through horizontal gene transfer. Five potential antimicrobial peptides and two CRISPR systems, which may confer resistance against phages, were also predicted.

<sup>2</sup>Food Technology, Technological Educational Institute of Peloponnese, Kalamata, Greece

<sup>3</sup>Institute of Biosciences and Applications, NCSR "Demokritos", Athens, Greece

### **Background**

Probiotics provide health benefits to the host upon ingestion. Lactic acid bacteria are frequently used as probiotics. Important qualifying characteristics of probiotics strains are the acid and bile resistance, the absence of pathogenic traits, the elevated adhesion ability, the production of antimicrobial substances and the inhibition of pathogens. Traditional fermented foods constitute a promising source for discovering new probiotic strains.

### **Objectives**

Lactic acid bacteria isolated from Greek traditional dairy (Yogurt and Feta, Kasseri, Xynotyri, Graviera, Kopanisti, Formaella, Galotyri, Kefalotyri cheeses) and meat (Lountza and Salami) products, were screened for their probiotic potential.

### **Methods**

The isolated strains were evaluated for survival to low pH and in the presence of bile salts. The safety of selected strains was assessed by studying their haemolytic activity and their susceptibility to commonly used antibiotics. Antimicrobial activity against pathogens, was also examined. Finally, the ability of the strains to adhere to collagen-coated 96-well microplates and to the human colorectal adenocarcinoma cell lines HT-29 and Caco-2 *in vitro*, was investigated.

### **Conclusions**

Of the 128 isolated strains, thirty were selected for further study due to their robust performance under the adverse conditions of the gastrointestinal tract. None of the strains exhibited haemolytic activity while variable antibiotic resistance was detected. Two *Streptococcus thermophilus* strains presented inhibitory activity against *Streptococcus anginosus* LMG 14502T and *Streptococcus mutans* LMG 14558T. Three *Lactobacillus plantarum* strains were found to adhere better to both cell lines,

as well as to the collagen-coated microplates. The utilization of *in vitro* tests enabled the selection of strains with promising probiotic features.

<sup>6</sup>Food Safety, Federal Food Safety and Veterinary Office, Bern, Switzerland

### **Background**

*Listeria monocytogenes* is an important foodborne pathogen with a significant impact on public health and economy worldwide. Human infections are rare, but *L. monocytogenes* has the potential to cause serious and life-threatening disease. Clinical conditions primarily comprise septicemia, meningitis, meningoencephalitis and abortion.

### **Objectives**

To describe a nationwide outbreak of listeriosis having occurred during 2013 to 2014 in Switzerland.

### **Methods**

Microbiological methods (serotyping, MLST, PFGE) and epidemiological investigations by telephone interviews were used.

### **Conclusions**

From 26 October 2013 to 23 April 2014, 32 cases of listeriosis infected with an *L. monocytogenes* strain serovar 4b, sequence type 4 and belonging to a single distinct PFGE pulsotype were registered in patients from several cantons of Switzerland. *L. monocytogenes* was detected in blood (75%), CSF (16%), ascites (6%) and in joint fluid (3%) samples. By the end of March 2014, a retail company reported an *L. monocytogenes* contamination of ready-to-eat salads to the authorities after detecting the pathogen through its in-house routine quality control. Product and environmental samples collected during subsequent investigations yielded isolates, matching the outbreak strain, thus confirming that ready-to-eat salad from this company was most likely the outbreak source. The cause for the product contamination was related to a design-inherent hygienic problem of one specific product-feeding belt. Complementary patient interviews also identified ready-to-eat green salads bought at one retailer as the likely outbreak source.

## **RAPID AND ACCURATE LISTERIA SPP. IDENTIFICATION BY MALDI BIOTYPER DATABASE IMPROVEMENT**

M. Awad<sup>1</sup>, M. Timke<sup>1</sup>, M. Kostrzewa<sup>1</sup>

<sup>1</sup>R&D Bioanalytics, Bruker Daltonic GmbH, Bremen, Germany

### **Background**

*Listeria* species are closely related to each other, however, only *L. monocytogenes* and *L. ivanovii* exhibit pathogenic features, (human cases of *L. ivanovii* infection being quite rare). Rapid, accurate identification of *Listeria* strains is essential for appropriate management and timely intervention for infection control.

The accuracy and speed of data acquisition by MALDI-TOF MS makes this an important tool for biological public health hazards, food processing, quality control, and disease diagnoses.

### **Objectives**

Since *Listeria* species are closely related and have similar profile spectra, the objective was to reliably identify the different *Listeria* species by MALDI-TOF MS through establishment of a reliable library of mass spectral *Listeria* fingerprints from reference strains. Therefore the database was enhanced by 52 *Listeria* strain references, from 9 species.

### **Methods**

*Listeria* strains were grown on Columbia Agar with 5 % Sheep Blood agar (BD, Heidelberg, Germany) at 37 °C. Biomass was collected after one day, and then processed by ethanol / formic acid standard extraction method. Mass spectra were acquired by using microflex LT (Bruker Daltonik, Bremen, Germany) and identified with MALDI Biotyper Compass software.

### **Conclusions**

With the new, optimized references database, it was possible to identify all tested *Listeria* strains from 9 species. This was proven by analysis of more than 1200 mass spectra.

Although log (score) value differences were small between *Listeria* species, the correct species was always the best match, no false identification occurred. In consequence, the important identification of the pathogenic *Listeria* species is possible with easy, rapid and reliable low-cost MALDI-TOF MS method.

**INCIDENCE OF ASPERGILLUS PRODUCER OF OCHRATOXIN A IN THE TROPICAL VITICULTURE IN THE NORTHEAST OF BRAZIL**

*L. Freire<sup>1</sup>, G. Pereira<sup>2</sup>, L. Batista<sup>1</sup>, F. Passamani<sup>1</sup>, C. Freire<sup>1</sup>*

<sup>1</sup>*Food Science, Federal University of Lavras, Lavras, Brazil*

<sup>2</sup>*SEMI-ÁRIDO, EMBRAPA, PETROLINA, Brazil*

**Background**

The biodiversity of filamentous fungi is one of the most important contributions to the occurrence of mycotoxins in agricultural products. The species belonging to the genus *Aspergillus* has been blamed for the presence of mycotoxins in wines. The incidence of these genera in grapes will depend on climatic conditions, grape variety, cultivation form and agricultural practices.

**Objectives**

This study aimed to identify *Aspergillus* species isolated from wine grapes at harvest, from organic and conventional vineyards, in the São Francisco Valley.

**Methods**

Varieties evaluated were Touriga Nacional and Ruby Cabernet, and Tempranillo. For the isolation of fungi direct plating was carried out in DRBC culture medium, 25°C/7 days. The isolates were identified using standard culture media. The determination of toxigenic potential was performed by Thin Layer Chromatography.

**Conclusions**

There was no presence of *Aspergillus* in the Tempranillo. All *A. carbonarius* were producers of ochratoxin A. The presence of these species can spoil the grapes. All species identified are naturally present in the vineyards.

**FEMS-1472**

**INCIDENCE OF OCHRATOXIGENIC SPECIES OF ASPERGILLUS AND OCHARATOXIN A ON COFFEE BEANS FROM CONVENTIONAL AND ORGANIC CULTIVATION**

*E. Rezende<sup>1</sup>, L. Batista<sup>1</sup>, G. Prado<sup>2</sup>, M. Oliveira<sup>2</sup>, F. Paschoa<sup>2</sup>, L. Paiva<sup>3</sup>*

<sup>1</sup>*Food Science, Federal University of Lavras, Lavras, Brazil*

<sup>2</sup>*Micotoxinas e Micologia de Alimentos, Fundação Ezequiel Dias, Belo Horizonte, Brazil*

<sup>3</sup>*IFSM, IFSM, Machado, Brazil*

**Background**

The natural microbiological contamination of fruit and coffee beans, are due to the presence of bacteria, yeasts and filamentous fungi, including fungi species of the genus *Aspergillus* ochratoxin-producing (OTA) has great relevance for coffee security.

**Objectives**

The objective of this study was to identify ochratoxigenics fungi and quantify the presence of OTA in conventional and organic cultivation of coffee beans in the southern region of Minas Gerais (Brazil) and compare the concentrations in both systems.

**Methods**

We analyzed 30 samples of coffee beans (*Coffea arabica* L.), 20 samples of conventional coffee and 10 organic coffee samples. The incidence of OTA in the samples of coffee beans was performed by high performance liquid chromatography (HPLC).

**Conclusions**

Samples were identified 480 fungi of the genus *Aspergillus* Section *Nigri* and *Circumdati*. The main producing species *Aspergillus ochraceus* was OTA (83% of the samples). For the OTA in the grain, only one sample collected organic coffee ground, presented OTA, 1.12 ug / kg. Considering these results, it can be stated that the presence of *Aspergillus ochraceus* OTA producer does not imply contamination of grain by mycotoxins and two coffee cultivation systems have the same risk of contamination.

**RATIONAL SELECTION OF YEASTS BASED ON THEIR PECTINOLYTIC ACTIVITIES AND ITS INCIDENCE ON TECHNOLOGICAL AND SENSORIAL ASPECTS OF WINE QUALITY**

I. Belda<sup>1</sup>, L.B. Conchillo<sup>1</sup>, J. Ruiz<sup>1</sup>, E. Navascués<sup>1</sup>, A. Alonso<sup>1</sup>, D. Marquina<sup>1</sup>, A. Santos<sup>1</sup>

<sup>1</sup>Microbiology III, Complutense University of Madrid, Madrid, Spain

**Background**

Pectinase enzymes have shown a considerable influence in both, sensitive and technological properties of wines. They can help to improve clarification and filterability process, releasing more color and flavor compounds entrapped in the grape skin and facilitating the liberation of phenolic compounds. The addition of commercial enzyme preparations, with filamentous fungi as its main source, can be quite expensive for industry.

**Objectives**

This work aims to find yeasts that, because of their native pectinases, can be applied on combined fermentations with *Saccharomyces cerevisiae* obtaining significant benefits over traditional wine fermentations.

**Methods**

785 yeast strains isolated from wineries were identified and tested for several enzymatic activities of recognized interest for enology industry. The impact of *Metschnikowia pulcherrima* as a source of pectinolytic enzymes during wine fermentation was analyzed by measuring its influence on filterability, turbidity and the increase on color, anthocyanin and polyphenol content of wines fermented in combination with *Saccharomyces cerevisiae*. Further metabolites with enological interest were analyzed during the entire fermentation period.

**Conclusions**

Positive results were obtained in all expected parameters when *M. pulcherrima* was used by comparing wines fermented with *S. cerevisiae* alone and combined with *Kluyveromyces thermotolerans*, even working better than commercial enzymes preparations in most parameters. Additionally, *M. pulcherrima* selected strain was used in a semi-industrial scale combined with three different *S. cerevisiae* strains, obtaining meaningful results on sensorial parameters like total polyphenol index, color intensity and turbidity of wines and on technological properties as wine filterability.

**DETECTION AND TYPING OF LACTOBACILLUS PARABUCHNERI, A  
POTENTIAL SPOILAGE ORGANISM, IN MILK AND CHEESE**

H. Berthoud<sup>1</sup>, D. Wüthrich<sup>2</sup>, R. Bruggmann<sup>2</sup>, D. Wechsler<sup>1</sup>, S. Irmeler<sup>1</sup>

<sup>1</sup>Institute for Food Sciences, Agroscope, Bern, Switzerland

<sup>2</sup>Interfaculty Bioinformatics Unit, University of Bern, Bern, Switzerland

**Background**

Histamine can be formed by microorganisms in fermented products such as cheese. High concentrations of this compound can trigger symptoms in consumers who have a histamine intolerance. Microbial decarboxylation of histidine is probably the major cause of histamine formation in cheese. We isolated histamine-producing bacteria from various raw-milk cheeses containing histamine levels higher than 50 mg kg<sup>-1</sup>. Partial sequence analysis of the *tuf* gene showed that all these bacteria belong to *Lactobacillus parabuchneri* which is closely related to *Lactobacillus buchneri*, a bacterium associated with spoilage in plant-based fermented food and beverages but which is also used in silage fermentation.

**Objectives**

The aims were to develop a real-time PCR for the specific and quantitative detection of *L. parabuchneri* in milk and cheese as well as a genotyping methods for strain discrimination and biodiversity estimation.

**Methods**

We sequenced the genome of *L. parabuchneri* FAM21731 and twelve other strains.

The draft genome sequence was compared to publicly available genome sequences of *L. buchneri* and other related species to identify a gene sequence which seems to be unique for *L. parabuchneri*. Sequences were submitted to Tandem repeats finder and CRISPRFinder to assess hypervariable sequences and their potential for strain discrimination.

**Conclusions**

Results show that the real-time PCR system is specific for the detection and quantification of *L. parabuchneri* in dairy products and that the multiplex PCR based on hypervariable sequences can discriminate strains.

The use of these methods is of interest since it can be employed to locate potential sources of *L. parabuchneri* contamination on farms and in dairy plants.

**DISCRIMINATION OF VIABILITY STATUS OF *SALMONELLA* TYPHIMURIUM CELLS INDUCED BY DISTINCT INACTIVATION METHODS USING A COMBINED FLOW CYTOMETRY, MALDI-TOF-MS AND MDA APPROACH**

R. Branquinho<sup>1</sup>, H. Osório<sup>2</sup>, A. Novais<sup>1</sup>, L. Peixe<sup>1</sup>, C. Sousa<sup>3</sup>

<sup>1</sup>*Ciências Biológicas - Laboratório de Microbiologia,*

*UCIBIO/REQUIMTE - Faculdade de Farmácia Universidade do Porto, Porto, Portugal*

<sup>2</sup>*IPATIMUP - Instituto de Patologia e Imunologia Molecular, Universidade do Porto, Porto, Portugal*

<sup>3</sup>*CEB – Centro de Engenharia Biológica, Universidade do Minho, Braga, Portugal*

**Background**

Food chain contamination with *Salmonella* Typhimurium is one of the leading causes of foodborne illness worldwide. Rapid and reliable methods for the detection of foodborne pathogens and also discrimination profiles concerning its cells viability status are deeply required and of high importance to assure foodborne pathogens control in the food chain.

**Objectives**

The goal of this study is to ascertain the *Salmonella* Typhimurium viability status (viable, viable non-culturable and non-viable) induced by distinct inactivation methods through a combined Flow Cytometry, MALDI-TOF-MS and multivariate data analysis (MDA) approach.

**Methods**

Different inactivation treatments, such as batch pasteurization (65°C; 30 minutes), sodium hypochlorite (5% or 0.006% commercial bleach), commercial available disinfectant solution (AMUKINA), ethanol (100%) and methanol (100%) were tested in *Salmonella* Typhimurium LT2. Cell viability assessment was evaluated by CFU's counts and Flow Cytometry (Accuri C6) with LIVE(TO)/DEAD(PI) dyes. In addition, footprint patterns of different viability states were obtained by MALDI-TOF-MS using HCCA as a matrix. Data were analyzed by MDA.

**Conclusions**

All the inactivation methods tested resulted in a total death of *Salmonella* Typhimurium LT2 population, with the exception of bleach (0.006%) and pasteurization, the latter used in industrial facilities. These treatments induced cells viable non-culturable state, which is of concern, since under favorable conditions *Salmonella* Typhimurium could restore viability and eventually its pathogenicity potential. Moreover, we obtained discriminatory peptide/proteins profiles associated with different viability states of *Salmonella* Typhimurium, which combined with MDA could support the use of this approach to detect microbiological contaminants applicable for quality control purposes.

## **INFLUENCE OF RAW MILK'S THERMODURIC DETERIORATING MICROBIOTA IN THE PASTEURIZED MILK'S SHELF LIFE**

C. Bruschi<sup>1</sup>, V. Beloti<sup>1</sup>

<sup>1</sup>LIPOA, Universidade Estadual de Londrina, Londrina, Brazil

### **Background**

The refrigerated storage of raw milk at the mill has advantages such as cost savings with the sample collection and reducing the loss of raw material. However, inadequate procedures during production and milk collection are considered the main sources of contamination by spoilage and pathogenic microorganisms, resulting in economic and public health problems.

### **Objectives**

The work aims to enumerate the thermotolerant microbiota found in raw milk and in the milk after pasteurization, correlating it with the shelf life of the product.

### **Methods**

Nine raw milk samples were collected directly from the extension tanks, nearby Castro – PR. After LTLT pasteurization, a portion of raw milk and pasteurized milk were diluted in peptone saline solution in the concentrations: integral, 10-1, 10-2 and 10-3, sown in depth amid PCA inverted and incubated at 35°C for 48 hours. Petrifilm plates ECTM for the enumeration of total coliforms and E. coli were also used. An aliquot was plated in depth for thermoduric counting in the same as described for the days when milk was pasteurized. The milk used for plating thermoduric was also inoculated in Petrifilm ECTM for controlling the progression of coliforms and E. coli.

### **Conclusions**

Four samples showed a reduction in the count of thermoduric microbiota between pasteurization and 25 days of experiment. Two samples obtained less than one log cycle of microbial growth, while three samples showed growth of thermoduric microorganisms, more than one log cycle in the same sampling period.

## **FENOLIC ACIDS EFFECTS ON PROBIOTIC BACTERIA GROWTH AND SURVIVAL**

C. Bruschi<sup>1</sup>, A. Oliveira<sup>1</sup>, N. Komora<sup>1</sup>, F. Campos<sup>1</sup>

<sup>1</sup>CBQF, Universidade Catolica Portuguesa, Porto, Portugal

### **Background**

The consumption of probiotics for colonization and maintenance of the intestinal microbiota, regulation of immune mechanisms and decrease of lactose intolerance is strongly credited through data already obtained by investigation. It is also a widespread antioxidative activity of phenolic acids the prevention of diseases related to oxidative stress such as cancer and cardiovascular diseases.

### **Objectives**

Analyse de groth behavior and tolerance of *Lactobacillus plantarum* and *Lactobacillus casei* when exposed to diferent fenolic acids-

### **Methods**

We examined the behavior of two probiotic bacteria *Lactobacillus plantarum* and *Lactobacillus casei* when exposed to four different concentrations of six different phenolic acids: caffeic, ferulic, p-coumaric, hydroxybenzoic, vanillic and protocatechuich. Over 48h, analyzes were conducted by using a spectrophotometer.

### **Conclusions**

In presence of acids hydroxybenzoic and protocatechuich, the absorbance increased slightly in the deceleration phase at a concentration of 50 mg/L and 100 mg/L, and decreases to a concentration of 200 mg/L compared to the values absorbance of the control. While for *L. casei*, was observed for all acids tested, the absorbance values at a concentration greater than 50 mg/L, and values approximately equal to a concentration of 200 mg/L, compared to the control absorbance values. For protocatechuich acid, ferulic acid and p-coumaric acid has been possible to verify that the absorbance values were higher than controls at a concentration of 100 mg/L . In all cases, it was found that 200 mg/L showed an effect similar to the control except hydroxybenzoic acid.

## **LISTERIA MONOCYTOGENES NMLR: ITS TRANSCRIPTOME AND ROLE IN STRESS RESPONSE**

S. Supa-amornkul<sup>1</sup>, S. Chaturongakul<sup>1</sup>

<sup>1</sup>Microbiology, Mahidol University, Bangkok, Thailand

### **Background**

NmlR, a transcription regulator in MerR family, is involved in oxidative and nitrosative stress responses in *Neisseria gonorrhoeae* and *Haemophilus influenzae*. A homolog is also found in a foodborne pathogen *Listeria monocytogenes* (Im).

### **Objectives**

In this study, in order to study the role of NmlR<sub>Im</sub> in *L. monocytogenes*, a null *nmlR<sub>Im</sub>* strain was constructed. Transcriptomes of 10403S wild type (WT) and its isogenic null *nmlR<sub>Im</sub>* mutant (MT) strains grown to stationary phase were determined. Phenotypes of these strains in response to different stress conditions were also assessed.

### **Methods**

RNAseq experiments were performed on Ion Torrent platform and the transcriptomes of WT and MT during stationary phase were identified. WT and MT strains were exposed to acid stress and oxidative stress conditions. Role of NmlR<sub>Im</sub> in virulence-associated phenotype was also evaluated in intracellular growth assay using U937 human macrophage-like cell line. Cell sizes of WT and MT were measured using transmission electron microscopy.

### **Conclusions**

RNAseq result reveals that NmlR<sub>Im</sub> negatively regulates 46 genes and positively regulates 28 genes. NmlR<sub>Im</sub>-dependent genes are grouped into 28 operons, eight of which overlap HrcA regulon, another negative regulator in *L. monocytogenes*. Phenotypic characterization revealed that MT strain survived significantly less than WT under acid stress (pH 2.5) and oxidative stress (3% hydrogen peroxide). Null mutation in *nmlR<sub>Im</sub>* also resulted in significant decrease in cell length and impaired intracellular growth in U937. Our findings indicate that NmlR<sub>Im</sub> is not only involved in oxidative stress response but also contributes to acid persistence and intracellular growth via either direct regulation or co-regulation with other regulators.

## **ADAPTATION AND TOLERANCE OF LACTOBACILLUS KEFIRANOFACIENS M1 TO VARIOUS ENVIRONMENTAL STRESSES**

M. Chiang<sup>1</sup>, H. Tang<sup>2</sup>, M. Chen<sup>2</sup>

<sup>1</sup>Department of Tourism and Hospitality, Kainan University, Taoyuan, Taiwan

<sup>2</sup>Department of Animal Science and Technology, National Taiwan University, Taipei, Taiwan

### **Background**

*Lactobacillus kefiranofaciens* M1, a novel probiotic strain isolated from Taiwanese kefir grains, has been demonstrated to possess anti-allergic, anti-asthmatic, anti-colitis and immunomodulatory effects in our previous in vitro and in vivo studies. These findings support that this strain has the potential to be applied in probiotic products. *L. kefiranofaciens* M1 must survive after processing, production and gastric passage to exert beneficial effects. Thus, the stress tolerance of *L. kefiranofaciens* M1 is important for its survivability.

### **Objectives**

This study was investigated the adaptation and tolerance of *L. kefiranofaciens* M1 to various environmental stresses.

### **Methods**

*L. kefiranofaciens* M1 was adapted to sublethal heat (37°C), cold (25°C), acid (pH 5), bile salts (0.05%), salts (0.1 M), ethanol (4%) and hydrogen peroxide (100 ppm) for 1 h and then challenged with lethal heat (52°C), cold (-20°C), acid (pH 3), bile salts (0.2%), salts (3 M), ethanol (20%) and hydrogen peroxide (1000 ppm), respectively.

### **Conclusions**

The results showed that adaptation to ethanol, hydrogen peroxide, salts and bile salts increased the tolerance of *L. kefiranofaciens* M1 to heat, cold, bile salts and ethanol stresses. Heat adaptation enhanced the tolerance to heat, bile salts and hydrogen peroxide. Acid adaptation caused an increased resistance to cold, acid, bile salts and hydrogen peroxide. Cold adaptation also induced cross-protection against cold, bile salts, salts and ethanol. However, ethanol- and cold-adapted cells decreased their survival after exposure to hydrogen peroxide. The occurrence of stress tolerance response in *L. kefiranofaciens* M1 varied depending on the type and condition of stress.

## **TRADITIONAL SOUR MILK FERMENTATION USING A POTENTIAL PROBIOTIC LACTOBACILLUS PLANTARUM STRAIN**

N.G. Chorianopoulos<sup>1</sup>, O.S. Papadopoulou<sup>1</sup>, E.E. Varzakis<sup>1</sup>, A.A. Argyri<sup>1</sup>,  
C.C. Tassou<sup>1</sup>

<sup>1</sup>*Institute of Technology of Agricultural Products,  
Hellenic Agricultural Organisation "DEMETER", ATHENS, Greece*

### **Background**

Probiotic foods receive market interest as health-promoting, functional foods.

### **Objectives**

To evaluate the performance of a *Lactobacillus plantarum* strain with probiotic potential as co-starter culture in sour milk fermentation and its ability to give a final product with desirable sensory characteristics.

### **Methods**

UHT milk was inoculated with *Streptococcus thermophilus* and *Lactobacillus delbrueckii* subsp. *bulgaricus* without (control case) or with *Lb. plantarum* and incubated in appropriate conditions (42°C, 6h). Fermented samples were stored at 4 and 12°C until the end of shelf life of product. Microbiological analysis was performed in parallel with pH and titratable acidity measurements as well as with sensory analysis of the product. The presence of the potential probiotic strain was determined using PFGE.

### **Conclusions**

On first day of storage, the population levels of all microbial groups exceeded 8 log cfu/ml for control and probiotic samples. During storage, the population levels were slightly elevated on probiotic samples compared to the control ones, whereas they were found to be above 8 log cfu/ml for all cases until the end of shelf life. The physicochemical properties (pH, titratable acidity) and the sensory characteristics of the potential probiotic product were similar to those of the control. According to PFGE the *Lb. plantarum* strain was recovered in high percentages during the products shelf life at both temperatures.

**Acknowledgment:** This work has been co-financed by the European Regional Development Fund (ERDF) of the EU and by National Resources under the Operational Program Competitiveness and Entrepreneurship (EPAN II), Action "COOPERATION 2011", Project "ProbioDairyMeat".

**GREEK FUNCTIONAL YOGHURT: ENHANCING THE PRODUCTION PROCESS USING A SELECTED LACTOBACILLUS STRAIN WITH PROBIOTIC POTENTIAL**

A.A. Argyri<sup>1</sup>, O.S. Papadopoulou<sup>1</sup>, E.E. Varzakis<sup>1</sup>, C.C. Tassou<sup>1</sup>,  
N.G. Chorianopoulos<sup>1</sup>

<sup>1</sup>*Institute of Technology of Agricultural Products,  
Hellenic Agricultural Organisation "DEMETER", ATHENS, Greece*

**Background**

Probiotic food products are in general fermented foods, with many studies reporting that the best matrices to deliver probiotics are dairy products, such as fermented milks and yogurt.

**Objectives**

To evaluate the performance of a *Lactobacillus plantarum* strain of dairy origin with probiotic potential as co-starter culture in Greek set-type yoghurt fermentation.

**Methods**

Low-pasteurized milk was inoculated with *Streptococcus thermophilus* and *Lactobacillus delbrueckii* subsp. *bulgaricus* (control) or with the former starters plus *Lb. plantarum* (probiotic) and incubated in 42°C for 5h. Subsequently, samples were stored at 4 and 12°C until the end of shelf life of the product. Microbiological analysis was performed in parallel with physicochemical and sensory analysis of the product. The presence of *Lb. plantarum* was determined using Pulsed Field Gel Electrophoresis (PFGE).

**Conclusions**

The initial levels of all microbial groups were above 7 log cfu/g for control and probiotic samples. During storage, the population levels of all counts were slightly elevated on probiotic samples compared to the control ones, whereas they exceeded the 7 log cfu/g at all cases. Probiotic yoghurt produced with *Lb. plantarum* strain exhibited a better sensory profile, with a rich traditional taste, but with similar physicochemical properties to the control. According to PFGE, the *Lb. plantarum* strain was recovered in high percentages during the products shelf life at both temperatures.

**Acknowledgment:** This work has been co-financed by the European Regional Development Fund (ERDF) of the EU and by National Resources under the Operational Program Competitiveness and Entrepreneurship (EPAN II), Action "COOPERATION 2011", Project "ProbioDairyMeat".

**IN VITRO ANTIBACTERIAL ACTIVITY AND COMPETITIVE INHIBITION EFFECT ON CACO-2 CELLS OF PROBIOTIC LACTOBACILLI ISOLATED FROM SARDINIAN DAIRY PRODUCTS**

M.L. Ciusa<sup>1</sup>, V. Mossa<sup>1</sup>, S. Viale<sup>1</sup>, A. Mancosu<sup>1</sup>, M.B. Pisano<sup>1</sup>, M.E. Fadda<sup>1</sup>, S. Cosentino<sup>1</sup>

<sup>1</sup>Public Health Clinical and Molecular Medicine, University of Cagliari, Cagliari, Italy

**Background**

The research of novel formulations with newly selected probiotic strains is important to satisfy the increasing request of the market and to obtain functional products with health-conferring properties. The most studied probiotic bacterial strains belong to the genus *Lactobacillus*, an important group of Lactic Acid Bacteria with functional and technological properties. Antagonistic activity toward potentially pathogenic microorganisms and adhesion to gut tissue are some of the main requirements when selecting successful probiotic strains.

**Objectives**

The aim of this work was to evaluate the antibacterial and anti-adhesion activity of *Lactobacillus plantarum* strains isolated from ewe's raw milk and their ability to *in vitro* colonize the intestinal epithelium. These strains were previously selected as potential probiotics because of their ability to survive at low pH values and physiological bile concentrations.

**Methods**

For detection of antagonistic activity, agar spot test and a well diffusion assay were performed toward *Escherichia coli* O157:H7, *Salmonella* Typhimurium and *Listeria monocytogenes*. The *in vitro* anti-adhesion effect was measured by a competitive inhibition assay on Caco-2 cells.

**Conclusions**

The results showed our strains having an excellent antibacterial activity against foodborne bacterial pathogens and anti-adhesion effect toward *E. coli* O157:H7 and *L. monocytogenes*, under the condition tested. Therefore, they showed interesting

probiotic characteristics. An *in vivo* study would be useful for a deeper evaluation of their properties, and their potential use in the development of novel functional food. This work has been supported by Regione Autonoma Sardegna (RAS, L.R. 7/2007).

**COOPERATION BETWEEN SPECIES IN THE YOGURT CONSORTIUM IS  
AFFECTED BY THE MODULATION OF INTRACELLULAR PH THAT IS DRIVEN  
BY STREPTOCOCCUS THERMOPHILUS UREASE ACTIVITY**

D. Mora<sup>1</sup>, S. Arioli<sup>1</sup>, M.C. Remagni<sup>2</sup>, M. Stuknyte<sup>2</sup>, S. Colombo<sup>2</sup>, S. Guglielmetti<sup>2</sup>,  
I. De Noni<sup>2</sup>, E. Ragg<sup>2</sup>

<sup>1</sup>Department of Food Environmental and Nutritional Sciences (DeFENS),  
University of Milan, Milan, Italy

<sup>2</sup>Department of Food Environmental and Nutritional Sciences (DeFENS),  
University of Milan and Sacco srl, Milan-Cadorago, Italy

**Background**

The proto-cooperation between *Streptococcus thermophilus* and *Lactobacillus delbrueckii* subsp. *bulgaricus* in the yogurt consortium enhances the growth rate and size of each population. In contrast, the independent growth of the two species in milk leads to a slower growth rate and a smaller population size.

**Objectives**

In this study, we evaluated how urease activity of *S. thermophilus* might affect the intracellular pH of *L. delbrueckii*, modulating its bioenergetics during milk fermentation.

**Methods**

Urease-mediated intracellular alkalization of *S. thermophilus* and *L. delbrueckii* was evaluated by flow cytometry using cFSE as pH-dependent fluorescent probe. Lactose consumption and lactic acid production was followed *in vivo* by <sup>13</sup>C-NMR analysis. D-L lactic acid production in milk was measured enzymatically. For the evaluation of the pH-dependent glycolysis efficiency, glucose and lactic acid were measured by HPLC.

**Conclusions**

We observed that intracellular alkalization caused by urea hydrolysis or the addition of ammonia to milk boosted lactic acid production in *S. thermophilus* and in *L. delbrueckii* when the species were grown separately or in combination. Therefore, we propose that urease activity acts as an altruistic cooperative trait, which is costly for urease-positive individuals but provides a local benefit because other individuals can take advantage of urease-modulated pH. Compared to the interactions that are known to occur between *S. thermophilus* and *L. delbrueckii* in the yogurt consortium, the modulation of the bioenergetic efficiency due to the intracellular pH alkalization represents a new type of cooperation that directly affects the kinetic parameters of enzymes involved in homolactic fermentation in both the species.

## **ESCHERICHIA COLI STRAIN DIVERSITY: SELECTING ISOLATES FOR USE AS PATHOGEN SURROGATES**

K. Cook<sup>1</sup>, E. Givar<sup>2</sup>, R. Taylor<sup>2</sup>

<sup>1</sup>Agricultural Research Service, USDA, Bowling Green, USA

<sup>2</sup>Department of Public Health, WKU, Bowling Green, USA

### **Background**

*Escherichia coli* (*E. coli*) is commonly used as a surrogate for pathogens in research to identify sources of agricultural contamination and to characterize how pathogens persist on plant surfaces. However, *E. coli* strains are highly diverse, exhibiting differences in physical, chemical and biological properties which contribute to fitness in secondary habitats.

### **Objectives**

An important step in selecting *E. coli* for use as pathogen surrogates is to identify strains with characteristics (including adhesion, motility and biofilm formation) that contribute to their occurrence and survival in a manner similar to that of pathogens.

### **Methods**

To this end, strain-level differences in genotype (adhesions (*iha*, *agn43*, *eaeA* and *fimH*, *kpsMTII*) and siderophores (*iroN<sub>E.coli</sub>*, *chuA*)) and phenotype (biofilm formation, curli expression, and growth rate) were evaluated for isolates from livestock (swine, poultry, dairy) and water sources. Selected *E. coli* isolates (n=18 of 1,300), a common *E. coli* control strain (ATCC 25922), and *Salmonella* (ATCC 13311) were used in soil studies to evaluate adhesion to plastic, sandy loam or clay soils.

### **Conclusions**

Average adhesion of environmental isolates to plastic was two-fold higher than that of the control strain. *Salmonella* and one of the environmental isolates had adhesion rates seven-fold higher than the control strain. That isolate had extremely high adhesion to clay ( $91.3 \pm 2.7\%$ ) and sandy loam ( $91.7 \pm 0.1\%$ ) soils, but had none of the genes commonly associated with adherence or biofilm formation. These results suggest that *E. coli* strain choice should be an important consideration in its use as a pathogen surrogate.

## **BACTERIAL TRANSCRIPTIONAL ADAPTATION TO NICHES: MOLECULAR AND METABOLIC RESPONSES OF LACTOBACILLUS PLANTARUM C2 IN PLANT SUBSTRATES**

R. Di Cagno<sup>1</sup>, P. Filannino<sup>1</sup>, M. Gobbetti<sup>1</sup>

<sup>1</sup>Department of Plant Soil and Food Sciences, University of Bari A. Moro, Bari, Italy

### **Background**

Raw fruits and some vegetables possess intrinsic chemical and physical features that make them particularly hostile environments for bacteria. To cope with environmental conditions, microorganism may adopt sophisticated adaptation mechanisms. The diversity of plant environments and of bacterial enzyme activities makes the microbial adaptation to plant niches markedly heterogeneous. *Lactobacillus plantarum* is a highly heterogeneous and versatile lactic acid bacteria frequently found or used in vegetables and fruits fermentation.

### **Objectives**

The aim of the study was to determine biological relevance of differentially expressed genes in *L. plantarum* C2 during fermentation of plant substrates, aiming to provide new insights into transcriptional response and niche adaptation.

### **Methods**

*L. plantarum* C2 was grown and stored in carrot or pineapple juices to mimic the chemical composition of the respective raw matrices. MRS broth was used as the control medium for optimal growth. Whole-transcriptome analysis based on customized microarray profiles has been used to determine altered transcription patterns in *L. plantarum* C2. These were compared with substrate utilization data gathered from high throughput phenotypic microarrays.

### **Conclusions**

Plant substrates exerted a transcriptional pressure and induced specific molecular and metabolic responses in *L. plantarum* C2. RNA and phenotypic microarray analyses revealed altered transcription patterns of genes encoding functions involved in primary metabolism, membrane transport, cofactors and vitamins metabolism, translation regulation, nucleotide metabolism, and fatty acid biosynthesis. Findings contribute to the description of bacterial transcriptional adaptation to niches, and provide a more solid basis for selection the most suitable starters for fermentation of targeted matrices.

**IN VITRO ASSESSMENT OF ANTIBACTERIAL ACTIVITY OF RESINS FROM SOME WOODY PLANT BUDS AND SYNERGISTIC EFFECT BETWEEN STANDARD PHENOLIC COMPOUNDS**

I. Dimkić<sup>1</sup>, T. Janakiev<sup>1</sup>, T. Berić<sup>1</sup>, P. Ristivojević<sup>2</sup>, D. Fira<sup>3</sup>, S. Stanković<sup>1</sup>

<sup>1</sup>Microbiology, Faculty of Biology University of Belgrade, Belgrade, Serbia

<sup>2</sup>Innovation Centre of Faculty of Chemistry,

Faculty of Chemistry University of Belgrade, Belgrade, Serbia

<sup>3</sup>Biochemistry and Molecular Biology, Faculty of Biology University of Belgrade, Belgrade, Serbia

**Background**

With emerging of new and reemerging of old infectious diseases, urgent need for new antimicrobial agents arises. Resins are complex mixtures of phenolic and isoprenoid compounds secreted by plants to provide protection against predators and pathogenic microorganisms.

**Objectives**

The present study was aimed at investigating the *in vitro* antimicrobial activity of resins from some woody plants on the selected bacterial strains. To elucidate origin of antimicrobial activity, potential synergistic effect between standard phenolic compounds was investigated, also.

**Methods**

The samples of resins were collected from different regions in Serbia and dissolved in methanol. Well diffusion and broth microdilution methods were implemented for assessing antimicrobial activity.

**Conclusions**

Gram-positive bacteria exhibited strong susceptibility to samples from *Populus* sp. while being resistant on samples from other origin. The most sensitive strain was *B. subtilis*, towards samples collected from *Populus nigra* and *Prunus avium* (MIC was 0,05 mg/ml). The strains of *S. aureus*, MRSA and *L. monocytogenes* showed similar sensitivity to poplar samples with MIC values mostly under 1 mg/ml. *L. monocytogenes* was also susceptible to cherry buds samples. Sample U19 from white poplar had significant antimicrobial activity on all tested strains, with lowest detected MIC values. Synergistic effect of gallic acid, quercetin and caffeic acid on *B. subtilis*; gallic, caffeic, p-coumaric acid and naringenin on *E. faecalis*; and gallic, caffeic acid and naringenin on *S. flexneri* was observed. In conclusion, antimicrobial activity of resins is probably outcome of action of phenolic compounds.

## **A COMPARISON OF LISTERIA SPP. PREVALENCE BETWEEN THE RAW FRESHWATER FISH FROM LAKE AND RETAIL MARKET IN LATVIA**

I. Eizenberga<sup>1</sup>, M. Terentjeva<sup>2</sup>, O. Valciņa<sup>3</sup>, A. Novoslavskij<sup>4</sup>, V. Strazdiņa<sup>5</sup>, J. Ošmjana<sup>1</sup>, A. Bērziņš<sup>3</sup>

<sup>1</sup>Laboratory of Food and Environmental Investigations,  
Institute of Food Safety Animal Health and Environment "BIOR", Riga, Latvia

<sup>2</sup>Institute of Food and Environmental Hygiene,  
Faculty of Veterinary Medicine Latvia University of Agriculture, Jelgava, Latvia

<sup>3</sup>Institute of Food Safety, Animal Health and Environment "BIOR", Riga, Latvia

<sup>4</sup>Department of Food Safety and Quality,  
Veterinary Academy Lithuanian University of Health Sciences, Kaunas, Lithuania

<sup>5</sup>Regional Laboratory of Sigulda,  
Institute of Food Safety Animal Health and Environment "BIOR", Sigulda, Latvia

### **Background**

Listeriosis is a foodborne infection caused by *Listeria monocytogenes*, which occurs due to ingestion of pathogen containing foodstuffs. *Listeria* spp. and *L. monocytogenes* are widespread in environment, but raw and processed fish products were found to be frequently contaminated with *Listeria* spp. Therefore fish are suspected to be a possible source for *Listeria* spp. including *L. monocytogenes* transmission to final food products.

### **Objectives**

The objectives of this study were to determine and compare the prevalence of *Listeria* spp. in raw freshwater fish from retail market and fish captured from lake in Latvia.

### **Methods**

A total of 51 raw freshwater fish samples were collected from lake (n = 11) and retail market (n = 39) in Latvia. A total amount of 25 g of fish skin, gut and muscle tissues of each fish was used for testing. Testing was performed in accordance to the International Organization for Standardization method (ISO 11290-1: 1996).

### **Conclusions**

The fish samples from lake were found to be *Listeria* spp. negative. In contrast, 69% of retail fish were found to be contaminated with *Listeria* spp. There were no significant differences between the prevalence of *L. innocua* and *L. monocytogenes* ( $p > 0.05$ ), while the prevalence of *L. ivanovii* and *L. welshimeri* was significantly lower than the prevalence of *L. monocytogenes* and *L. innocua* ( $p < 0.05$ ). The results

indicate that fish contamination with *Listeria* spp. may occur during fish handling, and the high prevalence of *L. monocytogenes* in raw fish at retail level can pose a threat for public health.

**GENOTIPIIC DIVERSITY AND ANTIMICROBIAL RESISTANCE OF SALMONELLA TYPHIMURIUM STRAINS ISOLATED HUMANS AND FOOD BETWEEN 1983-2013**

*F. Almeida<sup>1</sup>, M.I.C. Medeiros<sup>2</sup>, D.P. Rodrigues<sup>3</sup>, J.P. Falcao<sup>1</sup>*

<sup>1</sup>*Clinical Analyses Toxicology and Food Sciences,*

*School of Pharmaceutical Sciences of Ribeirao Preto - University of Sao Paulo, Ribeirão Preto, Brazil*

<sup>2</sup>*Bacteriology, Adolfo Lutz Institute of Ribeirao Preto, Ribeirão Preto, Brazil*

<sup>3</sup>*Bacteriology, Oswaldo Cruz Foundation - FIOCRUZ, Rio de Janeiro, Brazil*

**Background**

The foodborne disease caused by *Salmonella* Typhimurium is a major health problem worldwide.

**Objectives**

The aims of this study were to genotype *S. Typhimurium* isolated in Brazil and to verify its antimicrobial resistance profiles.

**Methods**

A total of 92 *S. Typhimurium* strains, isolated from humans (43) and food (49), between 1983 and 2013 in Brazil, were typed by PFGE, ERIC-PCR and MLVA. Additionally, their antimicrobial resistance was evaluated. **Results:** The 92 *S. Typhimurium* strains were grouped in two clusters, by PFGE, PFGE-A and PFGE-B (subdivided in PFGE-B1 and PFGE-B2); by MLVA in two clusters, MLVA-A and MLVA-B (subdivided in MLVA-B1 and MLVA-B2). By ERIC-PCR, in three clusters, ERIC-A, ERIC-B and ERIC-C. The strains isolated from humans before the mid-1990s were allocated in the PFGE-A, PFGE-B1, PFGE-B2, MLVA-A, MLVA-B1, MLVA-B2, ERIC-A and ERIC-B. The strains isolated from humans after mid-1990s were distributed in the PFGE-B1, MLVA-B1, MLVA-B2 and ERIC-A. The strains isolated from food were distributed in the PFGE-A, PFGE-B1, MLVA-A, MLVA-B1, MLVA-B2, ERIC-A, ERIC-B and ERIC-C. Twenty-three (25%) strains were multidrug resistance.

**Conclusions**

The results suggest that the studied strains isolated from humans before the mid-1990s were genetically more diverse, which might indicate that selection of a more adapted *S. Typhimurium* subtype occurred after *S. Enteritidis* became the most prevalent serovar in Brazil. Regarding, the food strains the results suggest the current circulation of more than one subtype. The occurrence of multi-drug resistant strains isolated from food is an alert for the possible risk for human consumption.

## **MOLECULAR CHARACTERIZATION AND RESISTANCE PROFILE OF CAMPYLOBACTER COLI STRAINS ISOLATED FROM DIFFERENT SOURCES IN BRAZIL**

C.N. Gomes<sup>1</sup>, J. Passaglia<sup>1</sup>, R.A. Souza<sup>1</sup>, M.I.C. Medeiros<sup>2</sup>, S.S. Duque<sup>3</sup>,  
J.P. Falcao<sup>1</sup>

<sup>1</sup>*Clinical Analyses Toxicology and Food Sciences, University of Sao Paulo-School of Pharmaceutical Sciences of Ribeirao Preto, Ribeirão Preto, Brazil*

<sup>2</sup>*Bacteriology, Adolfo Lutz Institute of Ribeirao Preto, Ribeirão Preto, Brazil*

<sup>3</sup>*Bacteriology, FIOCRUZ Institute, Ribeirão Preto, Brazil*

### **Background**

*Campylobacter coli* is an important causative agent of human diarrheal diseases worldwide. However, in Brazil is not frequently studied.

### **Objectives**

This study aimed to genotype and to investigate the presence of virulence genes and the resistance profile in *C. coli* strains.

### **Methods**

A total of 58 *C. coli* strains isolated from humans(10), animals(14), the environment(18) and food(9), between 1995-2011 in Brazil, were genotyped by PFGE. The presence of 16 virulence genes was searched by PCR. The resistance profile was obtained by MIC for erythromycin, ciprofloxacin, tetracycline and doxacycline. All the strains presented the genes *flaA*, *cadF* and *sodB*. The *cdtB*, *flhA*, *dnaJ* and *pldA* genes were observed in 20, 15, 10 and 6 strains, respectively. The *ciaB*, *iamA*, *cdtA*, *cdtC*, *docA*, *virB11*, *wlaN*, *racR* and *crsA* genes were not detected. PFGE grouped the strains in two main clusters with more than 45.4% of similarity. PFGE-A and PFGE-B clusters comprised 42 and 16 strains, respectively. In both clusters, strains of clinical and non-clinical sources were grouped in subclusters with a similarity value of more than 80%. The resistance profile showed that 19 strains, mainly of non-clinical sources, were resistant to at least one antimicrobial agent.

### **Conclusions**

The PFGE results confirmed the heterogeneity of the *C. coli* strains studied. However, the high similarity (>80%) among some strains of different origins suggests a possible contamination between clinical and non-clinical sources in Brazil. Because of these, the existence of resistant strains becomes a concern. The presence of important virulence genes indicates the pathogenic potential of those strains.

**ANTIBIOTIC RESISTANCE PROFILES AND PREVALENCE OF ENTEROTOXIN GENES OF STAPHYLOCOCCUS AUREUS FROM FOOD HANDLERS**

A. Fernandes<sup>1</sup>, V. Monteiro<sup>1</sup>, J. Guerreiro<sup>1</sup>, C. Ramos<sup>1</sup>, P. Fernandes<sup>1</sup>

<sup>1</sup>Escola Superior de Tecnologia e Gestão, Instituto Politécnico de Viana do Castelo, Viana do Castelo, Portugal

**Background**

*Staphylococcus* spp. are common members of the normal human flora. However, some *Staphylococcus* strains are recognized as human pathogens, in particular due to the production of several virulence factors and enterotoxins particularly relevant in food toxoinfections.

**Objectives**

Since many of the food toxoinfections by *S. aureus* are typically associated to cross-contamination, detection of *Staphylococcus aureus* was performed on food handlers.

**Methods**

Hand swabs from 167 food handlers were analysed for the presence of *Staphylococcus aureus* using Baird Parker agar and coagulase test, and genotypically confirmed by RT-PCR. A total of 26 strains were analysed using RT-PCR for the presence of virulence and enterotoxin genes, namely, *sea*, *seb*, *sec*, *sed*, *seg*, *sei*, *tsst1* and *pvl*. The same strains were phenotypically characterized in terms of antibiotic resistance using the disk diffusion method and antimicrobial agents from 15 different categories.

**Conclusions**

More than 11% of the samples were positive for *S. aureus*. A low prevalence of antibiotic resistant strains was found, with more than 55% of the strains being sensitive to all of the antimicrobial agents tested. However a high prevalence of resistance to macrolides was found, with 42% of the strains showing resistance to erythromycin. At least one of the virulence or enterotoxin genes was detected in 54% of the strains and the *seg* gene was detected in 42% of the strains.

**Food microbiology**

## **POTENTIAL GENETIC TARGETS FOR CONTROLLING CAMPYLOBACTER JEJUNI**

H. Velasco<sup>1</sup>, C. Girbau<sup>1</sup>, I. Martinez-Malaxetxebarria<sup>1</sup>, A. Guridi<sup>1</sup>, R. Alonso<sup>1</sup>,  
A. Fernandez-Astorga<sup>1</sup>

<sup>1</sup>Immunology Microbiology and Parasitology,  
Faculty of Pharmacy University of the Basque Country, Vitoria-Gasteiz, Spain

### **Background**

Essential genes have been suggested to provide useful information for the development of new specific anti-infective agents in *C. jejuni*, as the major cause of bacterial gastroenteritis in humans worldwide (Stahl & Stintzi, 2011). To determine genetic regions that are present or highly prevalent in all *C. jejuni* strains could be also of interest as potential genetic targets for this purpose.

### **Objectives**

The aim of this study was to identify by microarray comparative genomic hybridization (MCGH) potential genetic targets for controlling *C. jejuni*.

### **Methods**

The prevalence of 1652 genes among 120 geographically diverse isolates obtained from different sources (human, chicken cattle, water and wild birds) was determined by MCGH using the BpG@S CJv3.0.0 microarray. As MCGH does not confirm the absence or divergence of the tested genes, the results were compared with those obtained by both MCGH and genomic sequencing in previous studies (Stabler *et al.*, 2013; van Tonder *et al.*, 2014).

### **Conclusions**

MCGH analysis detected 1366 genes (83%) with prevalence 90 % in the *C. jejuni* population studied. These genes included 816 genes (60%) recently proposed as core (van Tonder *et al.*, 2014), and 229 genes (28 %) proposed as essential gene candidates (Stahl & Stintzi, 2011; Metris *et al.*, 2011). A final list of 22 genes, including core and essential genes, was highlighted. All these genes encode products required for cell growth, and are therefore potential targets to consider for antimicrobial intervention strategies in *C. jejuni*.

**Food microbiology**

**THE EFFECT OF OSMOTIC DEHYDRATION PROCESS IN SUGAR BEET MOLLASES ON MICROBIOLOGICAL PROFILE OF CHICKEN MEAT**

I. Filipovic<sup>1</sup>, K. Mihajlovic<sup>1</sup>

<sup>1</sup>*Microbiological Department, SP Laboratory, Becej, Serbia*

**Background**

Osmotic dehydration is a water removal process, based on soaking food (fruit, vegetable, meat and fish) in a hypertonic solution. Recent research has shown that use of sugar beet molasses as a hypertonic solution improves osmotic dehydration process from technological, nutritional and microbiological aspect.

**Objectives**

Effect of osmotic dehydration process on microbiological profile of chicken meat was investigated in order to determine the usefulness of this technique as pre-treatment for further treatment of chicken meat.

**Methods**

Fresh breast chicken meat was cut into cubes of 1x1x1 cm and contaminated with *Escherichia coli*, *Listeria monocytogenes* and *Salmonella* spp in laboratory conditions prior the process of osmotic dehydration. The process was conducted during 5 hours at 44°C in sugar beet molasses as an osmotic medium. All microorganisms were tested according to ISO methodology: *Salmonella* spp EN ISO 6579:2002, *Listeria monocytogenes* EN ISO 11290-2:1998, *Escherichia coli* ISO 16649-2:2001, *Enterobacteriaceae* ISO 21528-2:2004 and total number of microorganisms EN ISO 4833-1:2013.

**Conclusions**

The results of the microbiological profile of fresh, contaminated and osmotically dehydrated chicken meat have shown that the numbers of all examined microorganisms have significantly statistically reduced after the process.

From presented results it can be concluded that process of osmotic dehydration in molasses significantly improves microbiological profile of treated chicken meat and it is suitable pretreatment for further chicken meat processing, providing microbiologically safe intermediate product.

**USE OF COMPARATIVE GENOMICS AND THIN LAYER CHROMATOGRAPHY TO IDENTIFY SECONDARY METABOLITES RESPONSIBLE FOR ANTI-GRAM NEGATIVE ACTIVITY IN BACILLUS AMYLOLIQUEFACIENS SUBSP. PLANTARUM**

J. Fischer<sup>1</sup>, P. Chanos<sup>1</sup>, M.A. Knudsen<sup>1</sup>, B. Stahl<sup>2</sup>, A. Hibberd<sup>3</sup>, T. Mygind<sup>1</sup>

<sup>1</sup>Antimicrobials & Antioxidants, Dupont, Brabrand, Denmark

<sup>2</sup>Genomics and Ecology of Microbes, Dupont, Madison, USA

<sup>3</sup>Genomics and Ecology of Microbes, Dupont, Wauskesha, USA

**Background**

Strong consumer demand for safe and high-quality products has continued to drive food and pet food producers to seek novel solutions targeting Gram-negative bacterial contamination, such as *Escherichia coli* and *Salmonella* spp.

**Objectives**

Since *Bacillus* spp. are known for their ability to produce antimicrobial compounds, culture supernatants of *Bacillus amyloliquefaciens* strains were evaluated and characterized for their antimicrobial properties. Furthermore, genome sequences were to be generated to provide insights to the mode of action.

**Methods**

Six *B. amyloliquefaciens* strains were used for the experiments. Titration of activity was conducted by measuring the halos in an agar well diffusion assay, employing an extensive range of bacteria and fungi. The effect of pH, heat and enzymes on the activity of the supernatants was expressed as a percentage of residual activity compared to non-treated samples. Draft genomes were generated by 454 FLX Titanium for each of the *Bacillus* strains and mined for the presence of secondary metabolites, which was furthermore confirmed with TLC-bioautography profiles of methanolic extracts.

**Conclusions**

All supernatants exhibited activity against important food related bacteria and fungi, including Gram negatives. Generally, considerable activity was retained after heating and at alkaline pH but not under acidic conditions. Whereas different enzymes had a variable effect on the antimicrobial activity. genomic data indicated that the *Bacillus* strains harboured gene clusters encoding proteins involved in the

production of an array of secondary metabolites, including several non-ribosomal peptide synthetases, polyketides, and ribosomally synthesized peptides, which could be responsible for the *in vitro* antimicrobial properties observed.

**BAYESIAN MODEL FOR RISK ASSESSMENT OF CONSUMPTION  
CAMPYLOBACTER CONTAMINATED POULTRY IN FINLAND**

M. Gonzalez-Jimenez<sup>1</sup>, M. Hakkinen<sup>2</sup>, A. Mikkilä<sup>1</sup>, J. Ranta<sup>1</sup>, P. Tuominen<sup>1</sup>

<sup>1</sup>Risk Assessment Research Unit, Finnish Food Safety Authority (EVIRA), Helsinki, Finland

<sup>2</sup>Food and Feed Microbiology Research Unit, Finnish Food Safety Authority (EVIRA), Helsinki, Finland

**Background**

According to the Register of Infectious Diseases, supplied by the National Public Health Institute (THL), in 2013 *Campylobacter sp.* was the leading cause of human bacterial infection in Finland with 4059 cases registered (incidence 76 cases/100000 inhabitants). However, the real number of cases is assumed to be considerably higher than the registered cases numbers. The prevalence of *Campylobacter sp.* in animal-derived foods is affected by its prevalence in the production farms and in the animals. The contamination of the final product is also dependent on procedures carried out in abattoirs and during the various stages of the food production chain. The handling of food contaminated with *Campylobacter sp.* in domestic or industrial kitchens may also lead to cross-contamination, either directly from raw meat to products that will not undergo further cooking or indirectly via work surfaces, hands or utensils.

**Objectives**

Estimating the prevalence and concentration of *Campylobacter* in fresh (chicken, turkey) meat (sampled at retail), as well as presenting a novel Bayesian model to assess the probability of infection and illness.

**Methods**

Bayesian modeling of prevalence and concentration using Openbugs software based on results from detection and quantification of campylobacters (chicken: 608 samples from 226 batches) and (turkey: 558 samples from 185 batches) using modified NMKL 119:2007 and ISO 10272-2:2006.

**Conclusions**

Risk of *Campylobacter* exposure from Finnish fresh poultry meat is mainly due to undercooking or cross-contamination especially during summertime. The model can be used to assess e.g. relative risks, with quantification of uncertainty based on the data.

**FEMS-0648**

**EFFECT OF ELECTRON BEAM IRRADIATION IN MINAS FRESCAL CHEESE  
ARTIFICIALLY CONTAMINATED WITH ENTEROHAEMORRHAGIC  
ESCHERICHIA COLI (EHEC) O157:H7**

A. Gonzalez<sup>1</sup>, R.N. Medeiros<sup>1</sup>, M.F. Lima<sup>2</sup>, J.R. Domingues<sup>1</sup>

<sup>1</sup>Bromatology, Universidade Federal Fluminense, Niterói, Brazil

<sup>2</sup>Biology, Universidade Federal Fluminense, Niterói, Brazil

**Background**

The enterohemorrhagic *Escherichia coli* (EHEC) O157:H7 has been known to cause food-borne outbreaks. Cheeses are among the main food products incriminated in these outbreaks. Characterized as a perishable food, the Minas frescal cheese (MFC) has potential risk for O157:H7 transmission. As a result, the development of new technologies for its conservation has been studied. The use of irradiation has proved to be one of the most convenient options.

**Objectives**

The objective of the present study was to evaluate the effect of electron beam irradiation (doses of 1.0, 1.5 and 2.0 kGy) in MFC artificially contaminated with O157:H7.

**Methods**

Samples were produced to microbiological analyzes, one non-contaminated and non-irradiated, one contaminated and non-irradiated and three contaminated and irradiated. And to thiobarbituric acid reactive substances concentration (TBARS) analysis, one non-irradiated and non-contaminated and three non-contaminated and irradiated.

**Conclusions**

Artificially contaminated and irradiated MFC samples presented a shelf life of ten storage days at 4°C. The dose of 1.5 kGy reduced 2 log the number of O157:H7 and the doses of 1.5 and 2.0 kGy eliminated O157:H7 from the artificially contaminated samples. The TBARS assay was conducted to evaluate if the effect of irradiation could influence in the stability of the lipid fraction present in the cheese. All irradiated cheeses showed TBARS values, over the 40 day storage period, lower than in the non-irradiated sample. Results presented here demonstrate electron beam irradiation of MFC artificially contaminated with O157:H7 is a viable solution and a promising alternative to ensure the safety and quality of this food product.

**FEMS-1067**

**BEHAVIOR OF SHIGA TOXIN-PRODUCING ESCHERICHIA COLI (STEC) O157:H7 AND O113:H21 UNDER THE EFFECT OF DIFFERENT LEVELS OF PH AND TEMPERATURE**

S.A.G. Marcel<sup>1</sup>, M.F.S. Bianca<sup>1</sup>, N.M. Raquel<sup>1</sup>, A. Gonzalez<sup>1</sup>

<sup>1</sup>Bromatology, Universidade Federal Fluminense, Niterói, Brazil

**Background**

Shiga toxin-producing *Escherichia coli* (STEC) cause hemorrhagic colitis, hemolytic uremic syndrome and bloody diarrhea.

**Objectives**

This work aimed to evaluate the effect of two individual factors (pH and temperature), and their interaction, on the multiplication and survival of STEC (O157:H7 and O113:H21) using statistics as a tool for development of the experimental design and the analysis of results.

**Methods**

Approximately 10<sup>8</sup> CFU per ml were inoculated into Trypticase Soy Broth at pH conditions (4.0, 4.5, 5.5, 6.5 and 7.0) and temperature (6, 10, 20, 30 and 35°C). The experimental design was prepared by a central composite design, generated by the software Statistica 7 (StatSoft, OK, USA), and given 11 trials including three central points and four axial points. Assays were performed in 22 h.

**Conclusions**

Were generated equations that model the bacterial behavior from a multiple linear regression model. In the study with the RJ 581 strain (O157:H7), variables, individually and combined, showed linear significant effect on the response, the effect of the variable pH being the most relevant, with R<sup>2</sup> equal to 0.94. Explaining the optimal conditions for the multiplication of the RJ 581 strain values are closer to pH 7.0 and 35°C. In the study with the RJ 702 strain (O113:H21), we observed that the independent and combined variables had no significant effect on the response. The R<sup>2</sup> of the model was 0.4, showing a low suitability of experimental design to RJ 702 strain.

## **LACTIC ACID BACTERIA AS ANTAGONIST AGENTS TO FOODBORNE PATHOGENS ON FRESH-CUT 'GOLDEN DELICIOUS' APPLES**

A. Graça<sup>1</sup>, D. Santo<sup>2</sup>, C. Nunes<sup>3</sup>, I. Ratão<sup>2</sup>, C. Quintas<sup>2</sup>

<sup>1</sup>*Faculdade de Ciências e Tecnologia, Universidade do Algarve, Faro, Portugal*

<sup>2</sup>*Instituto Superior de Engenharia, Universidade do Algarve, Faro, Portugal*

<sup>3</sup>*Centro Empresarial Gambelas, Universidade do Algarve, Faro, Portugal*

### **Background**

Food safety is a major concern in fresh-cut industry. Fresh-cut produce can become contaminated with foodborne pathogens during manipulation. Application of natural antimicrobial substances provides new opportunities for the control of pathogenic bacteria. Lactic acid bacteria (LAB) are known to have antagonistic effect against sensitive bacteria species/strains by the secretion of substances with antimicrobial activity.

### **Objectives**

The main objective of this work was to do a screening of 37 LAB isolates for antimicrobial activity on minimally processed 'Golden delicious' apples against the foodborne pathogens *Escherichia coli* O157:H7 NCTC 12900, *Salmonella enterica* subsp. *enterica* Michigan ATCC BAA-709, *Cronobacter sakazakii* ATCC 51329 and *Staphylococcus aureus* ATCC 25923.

### **Methods**

LAB studied were isolated from fresh-cut fruit purchased in the market. One g of fresh-cut apple was inoculated with the LAB followed by the inoculation of the pathogen at a concentration of  $10^8$  cfu/mL. Samples were incubated at 30 °C for 48 h and after the recovery of the pathogens were made on selective/differential mediums. Fresh-cut apples inoculated with only the pathogen were used as control.

### **Conclusions**

From the 37 LAB isolates 18 were capable to reduce all the pathogens more than 2 log cfu/g and 5 achieved a reduction of more than 3 log cfu/g for all the pathogens. *S. enterica* and *C. sakazakii* showed reduction with all the isolates studied and *E. coli* and *S. aureus* showed reduction with 36 of the 37 isolates. Results obtained support the potential use of LAB as biocontrol agents against foodborne pathogens in fresh-cut fruit.

## **FERMENTATION PROPERTIES AND POTENTIAL PREBIOTIC ACTIVITY OF A HIGH PURITY GOS ON IN VITRO GUT MICROBIOTA PARAMETERS IN HEALTHY INDIVIDUALS**

R. Grimaldi<sup>1</sup>, A. Costabile<sup>1</sup>, J. Vulevic<sup>2</sup>, G. Tzortzis<sup>2</sup>, G. Gibson<sup>1</sup>

<sup>1</sup>Food Science, University of Reading, Reading, United Kingdom

<sup>2</sup>Clasado Ltd, Clasado Ltd, Buckinghamshire, United Kingdom

### **Background**

Most *in vitro* and *in vivo* studies involving prebiotic oligosaccharides have been carried out using inulin and its fructooligosaccharide (IFS) derivatives, as well as various galactooligosaccharides (GOS). It has been shown that these food ingredients have the ability to improve selectively the growth of bifidobacteria and, consequently, lead to important changes in the gut microbiota composition that may confer health benefits to the host. Bimuno®, (Clasado Ltd., Buckinghamshire, UK) is a 50% mixture containing galactooligosaccharides (B-GOS) having multiple biological health activities within the colonic environment, beyond the stimulation of bifidobacteria and lactobacilli at genus level and it has been tested in different *in vitro* and *in vivo* studies.

### **Objectives**

The present study aimed to determine the *in vitro* potential of a new high GOS content version of Bimuno (65% GOS content), comparing to B-GOS used as positive control, in a pH and volume controlled dose response batch culture experiments. Three different doses of the high purity GOS (2.75, 1.38 and 0.92 g) were tested.

### **Methods**

Changes in the gut microbiota during a time course were identified by fluorescence *in situ* hybridisation (FISH), whilst the small-molecular weight metabolomic profiles and short chain fatty acids (SCFAs) were determined by NMR analysis and Gas Chromatography (GC), respectively.

### **Conclusions**

The High purity GOS showed positive modulation of the microbiota composition after 4h fermentation at the lowest dose compared to B-GOS. Moreover, the administration of the specific GOS induced a significant increase in acetate as the major SCFAs synthesized compared to propionate and butyrate concentrations.

**COMMON AND DIVERGENT FEATURES OF THE HEAT-RESISTANT SPOILAGE  
PROTEASE PRODUCING MICROBIOTA IN MILK FROM TWO DIFFERENT UHT-  
MILK PRODUCING COUNTRIES, BRAZIL AND BELGIUM**

M. Heyndrickx<sup>1</sup>, S.G. Machado<sup>2</sup>, D.M.S. Bazzoli<sup>2</sup>, J. De Block<sup>1</sup>, V. De Jonghe<sup>1</sup>,  
E. Van Coillie<sup>1</sup>, M.C.D. Vanettia<sup>2</sup>

<sup>1</sup>Technology and Food Science Unit, Institute for Agricultural and Fisheries Research,  
Melle, Belgium

<sup>2</sup>Department of Microbiology, Federal University of Viçosa, Viçosa, Brazil

**Background**

The majority of the bacteria from raw milk are inactivated by heat treatments commonly used in dairy industry (pasteurization or ultra-high temperature (UHT)). However, these treatments do not destroy heat-resistant spoilage enzymes such as proteases produced by certain psychrotrophic bacteria before processing.

**Objectives**

The first objective was to identify the main proteolytic micro-organisms in raw milk from Belgium and Brazil, two countries with a large UHT-milk production but under different primary production conditions which can influence the microbiota composition of raw milk. Secondly, the diversity of the protease enzymes was investigated in order to characterize the target of future spoilage detection assays .

**Methods**

Raw milk samples were stored at simulated conditions of farm storage and transport according to Brazilian and Belgian regulations, respectively. The highly proteolytic strains were polyphasically identified. Their protease enzymes were characterized for heat resistance, proteolytic activity in milk, casein zymogram analysis with MALDI-TOF identification of protein bands, and for gene sequence diversity.

**Conclusions**

The *Pseudomonas fluorescens* group together with *Ps. fragi* and *Ps. lundensis* were dominant in Belgian raw milk, while in Brazil, almost the same *Pseudomonas* spp. together with *Serratia liquefaciens* were dominant, the latter being an indication of less hygienic conditions during milking. Belgian isolates showed overall a significant higher proteolytic activity than most Brazilian isolates. The proteolytic activity from both sources was resistant to UHT conditions with the one from *S. liquefaciens* being the most heat resistant. It seems that the spoilage protease from *S. liquefaciens* is

unrelated to the heterogeneous *Pseudomonas* AprX protease.

**POLYPHASIC IDENTIFICATION OF THE DOMINANT MICROBIOTA OF PEELED BROWN SHRIMP (CRANGON CRANGON) STORED UNDER MODIFIED ATMOSPHERE PACKAGING AT 4 °C WITHOUT PRESERVATIVES**

M. Heyndrickx<sup>1</sup>, F. Calliauw<sup>1</sup>, K. Broekaert<sup>1</sup>, G. Vlaemynck<sup>1</sup>, T. De Mulder<sup>1</sup>, C. Michiels<sup>2</sup>

<sup>1</sup>Technology and Food Science Unit, Institute for Agricultural and Fisheries Research, Melle, Belgium

<sup>2</sup>Faculty of Bioscience Engineering, KU Leuven, Leuven, Belgium

**Background**

Brown shrimp are, like many seafood products, prone to rapid spoilage. The main factor limiting shelf life is microbiological activity. Specifically for brown shrimp without preservatives, the microbiota is dominated by the genera *Pseudoalteromonas* and *Psychrobacter* when stored under iced aerobic conditions, but the spoilage bacteria of shrimp when cool stored under modified atmosphere (MAP) conditions without preservatives, a product which is gaining popularity among consumers, are still unknown.

**Objectives**

The main objective was to evaluate the variation throughout the year and during storage in the microbial community of MAP packaged cooked and machine peeled shrimp (*Crangon crangon*) without preservatives and the description of the dominant spoilage microbiota after 7 days of shelf life at 4 °C.

**Methods**

Three series of shelf life experiments resulting from three sampling periods of cooked shrimps throughout the year were conducted with mechanically peeled shrimp stored in a modified atmosphere (40% CO<sub>2</sub> and 60% N<sub>2</sub>). Culture-dependent and – independent methods, notably (GTG)<sub>5</sub> clustering followed by 16S rRNA gene sequencing of isolates and 16S rRNA gene based DGGE in combination with metagenomics, were used to monitor the bacterial population in brown shrimp without preservatives.

**Conclusions**

According to culture dependent identification the microbiota of brown shrimp was dominated by *Arthrobacter bergerei*, *Shewanella putrefaciens*, *Aliivibrio* spp., *Psychrobacter* spp., *Brochothrix thermosphacta* and *Vagococcus salmoninarum*. Using the culture independent approach the dominating genus after 7 days of storage was *Carnobacterium*. Most of the micro-organisms identified through the complementary approach are known to contribute to spoilage, but for some (e.g. *V.*

*salmoninarum*) the spoilage potential is yet unknown.

## **DNAJ GENE AS A MOLECULAR DISCRIMINATOR WITHIN THE LACTOBACILLUS CASEI GROUP**

C. Huang<sup>1</sup>, L. Huang<sup>1</sup>, W. Chu<sup>1</sup>

<sup>1</sup>BCRC, Food Industry Research and Development Institute, Hsinchu, Taiwan

### **Background**

The current taxonomy of the *Lactobacillus casei* group comprises three closely related species: *L. casei*, *L. paracasei* and *L. rhamnosus*. Some strains of these species have probiotic features and are now widely used in the food industries. However, neither phenotypic nor the most frequently applied genotypic marker (16S ribosomal DNA) provides sufficient resolution for accurate identification of *L. casei* group.

### **Objectives**

The aim of this study was to use the *dnaJ* gene as a molecular marker for species-level discrimination and identification within the *L. casei* group.

### **Methods**

The degenerate primers (LcasDnaj-F1/R1) were designed for *dnaJ* gene amplification and sequencing. The relationships between the members of *L. casei* group were conducted based on sequence similarity and phylogenetic analysis. The species-specific primers were designed by analysing the highly variable regions of the *dnaJ* gene.

### **Conclusions**

Within the *L. casei* group, the nucleotide sequence similarity of *dnaJ* gene was significantly lower than that of 16S rRNA gene, and all examined strains could be clearly distinguished. In addition, the species-specific primers were developed, which were then employed for two-plex minisequencing analysis, and were shown to be specific for *L. paracasei* and *L. rhamnosus*. Our data indicate that the phylogenetic relationships in the *L. casei* group can be resolved using *dnaJ* gene sequencing, and the species of *L. paracasei* and *L. rhamnosus* can be identified using novel species-specific minisequencing assay.

<sup>2</sup>Interfaculty Bioinformatics Unit and Swiss Institute of Bioinformatics,  
University of Berne, Bern, Switzerland

**Background**

The formation of biogenic amines in cheese can occur as a result of the presence of bacteria possessing amino acid decarboxylase activity. One of the most important biogenic amines in cheese is histamine, since it can cause serious human health problems upon ingestion.

**Objectives**

To better understand the factors contributing to histamine accumulation, we isolated histidine decarboxylase positive lactic acid bacteria from various raw-milk cheeses with elevated histamine levels. All isolates belonged to the species *Lactobacillus parabuchneri*. Various factors, such as starter culture, proteolysis during ripening, storage temperature, salt concentration and pH can affect histamine formation in cheese. For cheeses made from raw milk, a thermal treatment of the milk prior to cheese making to reduce the numbers of histamine producing *L. parabuchneri* is not an option. Other strategies could be developed to prevent accumulation of biogenic amines if the metabolism of these bacteria is known in more detail.

**Methods**

RNA from *L. parabuchneri* FAM21731 grown at various pH was isolated and sequenced on an Ion Torrent PGM sequencer.

**Conclusions**

Whole transcriptome analysis of *L. parabuchneri* was established using next generation sequencing technology. The methodology helps us to better understand how cheese making technology and choice of starter culture influence the metabolism of histamine producing *L. parabuchneri* strains.

**EXPRESSION PROFILING OF *PEDIOCOCCUS ACIDILACTICI* FAM18098 WITH A FOCUS ON THREONINE AND SERINE CATABOLISM**

C. Bär<sup>1</sup>, C. Wenzel<sup>1</sup>, D. Wüthrich<sup>2</sup>, R. Bruggmann<sup>2</sup>, E. Eugster<sup>1</sup>, H. Berthoud<sup>1</sup>, S. Irmeler<sup>1</sup>

<sup>1</sup>Food Analytics, Agroscope Institut für Lebensmittelwissenschaften ILM, Bern, Switzerland

<sup>2</sup>Interfaculty Bioinformatics Unit and Swiss Institute of Bioinformatics, University of Berne, Bern, Switzerland

**Background**

Proteolysis and amino acid catabolism are the most important events taking place during cheese ripening. Microorganisms play a crucial role in these biochemical changes. Among various lactic acid bacteria *Pediococcus acidilactici* is often found in cheese at the end of ripening. Little is known if this species contributes to protein break down and flavor development in cheese. When *Pediococcus acidilactici* FAM18098 was used as adjunct culture in cheese making, we observed that it degraded arginine, serine and threonine and synthesized ornithine, alanine and 2-aminobutyrate during cheese ripening.

**Objectives**

*P. acidilactici* FAM18098 did not degrade serine and threonine under laboratory conditions using MRS broth, a broth usually used for lactic acid bacteria in the laboratory. By changing the composition of media, we found a medium in which this strain showed an amino acid metabolism similar to the one observed in cheese. By analyzing the transcriptome of *P. acidilactici* FAM18098 we want to better understand the transcriptional regulation of genes involved in amino acid metabolism and to find experimental conditions that are similar to the ones of cheese.

**Methods**

RNA from *P. acidilactici* FAM18098 grown in various media was isolated and sequenced on an Ion Torrent PGM sequencer.

**Conclusions**

We established a protocol to analyze and compare whole transcriptomes of *P. acidilactici* with next generation sequencing technology. With this methodology we studied genes that are involved in amino acid metabolism under conditions that probably mimic a cheese environment.

## **TRANSFER OF *L. MONOCYTOGENES* FROM DIFFERENT FOOD CONTACT SURFACES TO CHEESES**

R. Ismail<sup>1</sup>, P. GAY-PERRET<sup>2</sup>, I. LE BAYON<sup>3</sup>, F. AVIAT<sup>1</sup>, M. FEDERIGHI<sup>1</sup>,  
V. MICHEL<sup>2</sup>

<sup>1</sup>UMR INRA 1014 SECALIM, Oniris INRA, Nantes, France

<sup>2</sup>Actalia, Actalia produits laitiers, La Roche sur Foron, France

<sup>3</sup>FCBA Laboratoire de biologie, FCBA Bordeaux, Bordeaux, France

### **Background**

The food contact surfaces are subject to contamination by pathogens that could lead to cross-contamination by transfer events to others food products. However, the European regulation n° 1935/2004 of 27<sup>th</sup> October 2004 (Anonymous, 2004) specifies that materials intended for safe food contact must not interfere with foodstuff characteristics.

As a traditional and natural material, wooden boards are traditionally used as as a “technological tool” during cheeses ripening process. In France, wood is authorized for food contact by the French Arrêté November 1945 (Anonymous, 1945) and the information note of DGCCRF 2012-93(Anonymous, 2012).

### **Objectives**

The aim of this study was to determine the behavior of wooden surfaces in direct food contact, contaminated by a well-known risk along the production chain of dairy products: *Listeria monocytogenes*.

### **Methods**

For this purpose, a protocol was defined and new spruce boards were inoculated by *L. monocytogenes* solution at a concentration of 10<sup>5</sup> CFU/cm<sup>2</sup> and the microbial transfer to pressed non-cooked cheeses was studied. Factors such as cheese time contact, wood moisture content and age of the cheeses were tested.

A comparison of transfer quantification, with other materials surfaces: glass plates and plastic sheets with inclined meshes, used in cheese production, was also realized among the same conditions.

### **Conclusions**

The results showed for all tested surfaces a transfer yield below 3% (CFU/cm<sup>2</sup>) in the first hour. No differences were found for older cheeses or for higher wood moisture

content. In conclusion, wooden shelves are, as much as, safety for food contact than plastic or glass surfaces.

## **BIOFILM FORMATION AND VIRULENCE GENOTYPES OF ARCOBACTER BUTZLERI ISOLATED FROM FOOD PRODUCTS**

C. Guerra<sup>1</sup>, G. Muruaga<sup>1</sup>, C. Iturralde<sup>1</sup>, I. Martinez-Malaxetxebarria<sup>1</sup>, R. Alonso<sup>1</sup>, A. Fernandez-Astorga<sup>1</sup>

<sup>1</sup>Immunology Microbiology and Parasitology,

Faculty of Pharmacy University of the Basque Country, Vitoria-Gasteiz, Spain

### **Background**

Manipulation or consumption of raw or poorly cooked foods of animal origin is an important source of human infection with the emerging food and waterborne pathogen *Arcobacter butzleri*. The ability of this bacterium to form biofilm favors the transmission and its adherence to food and food-contact surfaces possibly favors cross-contamination. Preventing cross-contamination is a key factor in Food Safety. Besides, studying the virulence properties of any potentially pathogenic foodborne bacteria is essential for the consumer safety.

### **Objectives**

The aim of this study was to determine the biofilm formation ability of 42 *A. butzleri* isolates obtained from different food products and to study the prevalence of ten putative virulence genes among adherent isolates.

### **Methods**

Biofilm formation was assayed by microtiter plate method (Teh *et al.*, 2010) and categorized according to Naves *et al.* (2008). Putative virulence genes were studied by PCR (Doudah *et al.*, 2012; Karadas *et al.*, 2013).

### **Conclusions**

Eight isolates were categorized as weakly adherent and one isolate as strongly, under the tested conditions. Adherence was not related with a specific food product. The genes *cadF*, *ciaB*, *cj1349*, *mviN*, *pldA* and *tlyA* were detected in all adherent isolates; whilst *iroE* (4/9), *hecA* (1/9) and *hecB* (2/9) were detected only in few. *irgA* was not detected.

The occurrence of adherent *A. butzleri* isolates possessing virulence markers in food products of animal origin is an important factor to consider for the foodborne illness risk assessment.

**SOURCE TRACKING GENETIC MARKERS IN CAMPYLOBACTER JEJUNI BY MLST AND MCGH**

H. Velasco<sup>1</sup>, C. Girbau<sup>1</sup>, I. Martinez-Malaxetxebarria<sup>1</sup>, A. Fernandez-Astorga<sup>1</sup>, R. Alonso<sup>1</sup>

<sup>1</sup>Immunology Microbiology and Parasitology,

Faculty of Pharmacy University of the Basque Country, Vitoria-Gasteiz, Spain

**Background**

*Campylobacter jejuni* is a major cause of food-borne diarrheal illness in humans worldwide. Despite being a well known food and water-borne zoonosis, establishing the source of campylobacteriosis is still complicated (Hepworth *et al.*, 2011).

**Objectives**

The aim of this study was to find genetic markers for clonal complex (CC) and source attribution in *C. jejuni*.

**Methods**

Multilocus sequence typing (MLST) and microarray-based genomic hybridization (MCGH) were applied to 69 *C. jejuni* isolates from different sources (wild birds, surface and wastewater, and human and bovine feces). Oligonucleotide DNA microarrays (BµG@S CJv3.0.0) were used to compare *C. jejuni* isolates, with *C. jejuni* NCTC 11168 and RM1221 as reference strains.

**Conclusions**

The population was genetically diverse. MLST differentiated the isolates into 38 sequence types (STs), of which 29 were included in seven different CCs. Ten new alleles were identified, which resulted in the assignment of 12 new STs.

MCGH confirmed most of the previously described variable and/or plasticity regions (Parker *et al.*, 2006; Hepworth *et al.*, 2011; Stabler *et al.*, 2013). Combining MLST and MCGH results allowed us to detect several potential genetic markers associated with both, specific CCs and certain sources of isolation. More accurately, the genes *cas2*, *cas1*, *Cj0659c-Cj0660c*, *Cj0887c*, *Cj1041-Cj1042*, *hsdM* and *hsdR* related with the CCs ST-21, ST-42, ST-177 and ST-677; and the genes *glpT*, *ldh* and *Cj1562* related with isolates from wild birds.

**FEMS-1054**

**Food microbiology**

## **GENETIC DIVERSITY AND HORIZONTAL GENE TRANSFER IN FOODBORNE ARCOBACTER CRYAEROPHILUS ISOLATES**

R. Alonso<sup>1</sup>, C. Girbau<sup>1</sup>, H. Velasco<sup>1</sup>, I. Martinez-Malaxetxebarria<sup>1</sup>, A. Fernandez-Astorga<sup>1</sup>

<sup>1</sup>Immunology Microbiology and Parasitology,

Faculty of Pharmacy University of the Basque Country, Vitoria-Gasteiz, Spain

### **Background**

*Arcobacter* species have been recognized as potential food- and waterborne pathogens, and are implicated in human enteritis. The wide genetic diversity reported among *Arcobacter* species reflects the continuous evolving nature of these pathogens.

### **Objectives**

The aim of this work was to determine the genetic diversity and virulence gene content of 10 *Arcobacter cryaerophilus* isolates obtained from clams, mussels and raw cow milk obtained in Vitoria, Spain.

### **Methods**

Genetic diversity was studied by multilocus sequence typing (MLST). The obtained genotypes were analyzed using the MEGA 5.1 software, and possible recombination events were evaluated in silico using the RDP3 software. Recombination events were considered when detected by at least 3 methods. The presence of nine putative virulence genes was determined by PCR.

### **Conclusions**

A total of 9 sequence types (ST) not previously described were identified among the 10 isolates. All the isolates harbored virulence genes. The most frequent were *ciaB* and *mviN* (100%), followed by *tlyA* (40%) and *hecA* (30%). Due to the incongruent phylogenetic relationships observed for *glnA* and *glyA* genes, recombination analysis was performed. This analysis detected potential recombination events in the ST413, ST415 and ST416 isolates, probably derived from interspecies recombination between *A. cryaerophilus* and *A. skirrowii*.

From these results, we conclude that MLST typing showed high strain diversity and that recombination should be considered as a potentially relevant mechanism generating genetic diversity in *A. cryaerophilus*.

**FEMS-1758**

## **FURTHER EVIDENCE FOR STAPHYLOCOCCAL FOOD POISONING OUTBREAKS CAUSED BY SEG AND SEI**

S. Jöhler<sup>1</sup>, P. Giannin<sup>2</sup>, M. Jermin<sup>2</sup>, J. Hummerjohann<sup>3</sup>, A. Baumgartner<sup>4</sup>,  
R. Stephan<sup>1</sup>

<sup>1</sup>University of Zurich, Institute for Food Safety and Hygiene, Zurich, Switzerland

<sup>2</sup>Cantone Ticino, Cantonal Laboratory, Bellinzona, Switzerland

<sup>3</sup>Institute for Food Sciences, Agroscope, Bern, Switzerland

<sup>4</sup>BAG, Federal Food Safety and Veterinary Office, Bern, Switzerland

### **Background**

Staphylococcal food poisoning represents the most prevalent foodborne intoxication worldwide. It is caused by oral intake of enterotoxins preformed by *Staphylococcus aureus* in food. The relevance of enterotoxins SEG and SEI in outbreaks of staphylococcal food poisoning is controversially discussed. Although SEG and SEI elicit emesis in a monkey feeding assay, there has been no conclusive proof of their emetic activity in humans.

### **Objectives**

In this study, we present novel evidence suggesting that SEG and SEI can cause staphylococcal food poisoning and describe the special challenges associated with investigating outbreaks linked to SEG and SEI.

### **Methods**

We analyzed all outbreaks registered with the Swiss Federal Office of Public Health, in which only *Staphylococcus aureus* strains harboring *seg* and *sei* linked to typical signs of staphylococcal food poisoning were isolated (n = 3).

### **Conclusions**

The outbreaks were caused by consumption of raw goat cheese, potato salad, and semi-hard goat cheese, and were linked to strains assigned to CC45 (*agr* type I), CC30 (*agr* type III), and CC9 (*agr* type II), respectively. Investigation of the outbreaks was particularly challenging as, in contrast to classical staphylococcal enterotoxins, there are currently no suitable methods for detection of SEG and SEI in food and feces. Our data provides strong evidence suggesting that SEG and SEI can cause staphylococcal food poisoning in humans. Further research will be necessary to determine the individual role of SEG and SEI in outbreaks.

**FOOD POISONING OUTBREAK AMONG CHILDREN AND STAFF AT SWISS BOARDING SCHOOL DUE TO RAW MILK CHEESE CONTAMINATED WITH STAPHYLOCOCCUS AUREUS OF GENOTYPE B**

S. Johler<sup>1</sup>, D. Weder<sup>2</sup>, C. Bridy<sup>2</sup>, M.C. Huguenin<sup>2</sup>, R. Luce<sup>2</sup>, J. Hummerjohann<sup>3</sup>

<sup>1</sup>Institute for Food Safety and Hygiene, University of Zurich, Zurich, Switzerland

<sup>2</sup>Service de la Consommation et des Affaires Vétérinaires, Canton de Neuchâtel, Zurich, Switzerland

<sup>3</sup>Institute for Food Sciences, Agroscope, Zurich, Switzerland

**Background**

In 2014, an outbreak of staphylococcal food poisoning occurred at a Swiss boarding school due to consumption of Tomme, a soft cheese produced from raw cow milk. All 14 persons that had ingested the cheese fell ill, among them ten children.

**Objectives**

We present a food poisoning outbreak caused by raw milk cheese contaminated with a *Staphylococcus* (*S.*) *aureus* strain of genotype B.

**Methods**

The Tomme cheese was tested for presence of staphylococcal enterotoxins and *S. aureus* strains isolated from the cheese were characterized by *spa* typing and a DNA microarray.

**Conclusions**

The cheese exhibited low levels of staphylococcal enterotoxin A (> 6 ng SEA/g cheese) and high levels of staphylococcal enterotoxin D (> 200 ng SED/g cheese). A total of 10<sup>7</sup> CfU coagulase-positive *Staphylococci* per gram cheese were detected, with three different *S. aureus* strains being present at levels higher than 10<sup>6</sup> CfU/g. A strain exhibiting *sea* and *sed* was identified as the source of the outbreak. The strain was assigned to *spa* type t711 and CC8 and exhibited genetic criteria consistent with the characteristics of a genotype B strain. This genotype comprises bovine *S. aureus* exclusively associated with very high within-herd prevalence of mastitis and has been described as a major contaminant in Swiss raw milk cheese. It is highly likely that the raw milk used for production of the Tomme was strongly contaminated with *S. aureus* and that levels further increased due to growth of the organism and physical concentration effects during the cheese making process.

**Food microbiology**

**TEMPORAL EXPRESSION OF THE STAPHYLOCOCCAL ENTEROTOXIN D GENE UNDER NaCl STRESS CONDITIONS ENCOUNTERED DURING FOOD PRODUCTION AND PRESERVATION**

H.M. Sihto<sup>1</sup>, T. Tasara<sup>1</sup>, R. Stephan<sup>1</sup>, S. Johler<sup>1</sup>

<sup>1</sup>*Institute for Food Safety and Hygiene, University of Zurich, Zurich, Switzerland*

**Background**

*Staphylococcus aureus* represents one of most osmotolerant food-borne pathogens. While its growth is repressed by competing bacteria, the organism exhibits a growth advantage at increased salt concentrations. Staphylococcal enterotoxin D (SED) leads to vomiting and diarrhea upon consumption. To date, the effect of NaCl on both *sed* expression and its regulatory control are unclear.

**Objectives**

We aimed to determine the impact of NaCl stress on *sed* expression and the influence of *agr*, *sarA*, and *sigB* on *sed* expression under NaCl stress.

**Methods**

Using qPCR, temporal expression of *sed* in LB and LB with 4.5% NaCl was compared, as well as *sed* expression between wild type strains and isogenic  $\Delta agr$ ,  $\Delta sarA$ , and  $\Delta sigB$  mutants.

**Conclusions**

In general, NaCl stress led to decreased *sed* expression. However, one strain exhibited a trend towards increased *sed* expression under NaCl stress. One  $\Delta sarA$  mutant each showed decreased *sed* expression in the early stationary and increased *sed* expression in the stationary growth phase under NaCl stress. No significant effect of *agr* on *sed* expression was detected, and only one  $\Delta sigB$  mutant showed a significant decrease in *sed* expression in the early stationary phase under NaCl stress. These findings suggest high strain-specific variation in *sed* expression and its regulation under NaCl stress.

**TRACKING CHANGES OF BACTERIAL COMMUNITY COMPOSITION IN A  
LARGE INTESTINAL MODEL SYSTEM BY QPCR**

Á. Juhász<sup>1</sup>, L. Szabó<sup>1</sup>, K. Mikuska<sup>1</sup>, K. Pál<sup>1</sup>, K.Z. Váczy<sup>1</sup>

<sup>1</sup>Egerfood Regional Knowledge Centre, Eszterházy Károly College, Eger, Hungary

**Background**

In vitro digestion models are simplified artificial systems to simulate digestion processes in humans/animals. Our digestion system aimed to study structural changes, digestibility and bioavailability of food components and behaviour of microbes. The model consisted of four stages, imitating the environment of mouth, stomach, small intestine and large intestine.

**Objectives**

Selective agar plates ensured reliable enumeration of bacterial colonies, but cultivation took 2-3 days, especially in case of the slowly growing species (e.g. *Bifidobacterium*), therefore, qPCR technique was applied for enumeration of bacteria.

**Methods**

Microbial activity was investigated in the large intestinal phase. Bacterial community consisted of two probiotic (*Bifidobacterium* and *Lactobacillus*) and four neutral/potential pathogenic species (*Clostridium*, *Bacteroides*, *Enterococcus*, *Escherichia*), found frequently in the human large intestine. The effect of food components (including prebiotic carbohydrates) on proliferation and survival of bacteria was evaluated on selective agar plates and by qPCR, using newly designed species-specific primers in the latter case.

**Conclusions**

The use of species specific primers for qPCR-based quantitation was successful, the number of each bacteria was determined precisely. Differences between the plate count and qPCR techniques were within an order of magnitude range in most cases. However, selective agar plates are still widely used for enumeration of bacteria in laboratories, other methods like qPCR are used more and more frequently, due to their speed and reliability. Our experiments showed that carefully selected primers were able to ensure the specificity for quantitation of bacteria from mixed cultures, in the presence of interfering compounds, such as digestion juice.

**Food microbiology**

**EFFECT OF OZONATED AND CHLORINATED WATER ON MICROBIOLOGICAL LOAD AND SENSORY PROPERTIES OF FRESH LETTUCE (*LACTUCA SATIVA*) AND BROCCOLI (*BRASSICA*)**

P. Gogos<sup>1</sup>, A. Mavromatis<sup>2</sup>, I. Arvanitogianis<sup>3</sup>, K. Kakavas<sup>4</sup>

<sup>1</sup>Department of Medicine, University of Thessaly, LARISSA, Greece

<sup>2</sup>Department of Agricultural Sciences & Rural environment, University of Thessaly, Volos, Greece

<sup>3</sup>Department of Ichthyology and Aquatic Environment, University of Thessaly, Volos, Greece

<sup>4</sup>School of Technological Applications,  
Technological Educational Institute of Thessaly, Karditsa, Greece

**Background**

Ozonated and chlorinated water used as potential antimicrobials agents in food industry. Since 2001, when US Food and Drug Administration (FDA) announced the permission of Ozon's usage as a suitable antimicrobial agent for food, many investigations have been applied (Singh et al. 2002, Trinetta et al. 2011).

**Objectives**

The objectives of this experimental work are to determine the effectiveness of ozonated (33.3 mg/l) and chlorinated (50 mg/l) water on the reduction of microbiological load on two vegetable species. The project's target is to estimate the load of four pathogen microorganisms (*Echerichia coli*, *Listeria monocytogenes*, *Salmonella* spp, *Enterobacteriaceae*) at the different market points and highlight if those specific vegetables are safe for the consumers. One more target is to remark any changes at the qualitative and sensory characteristics. Furthermore, was examined the microbiological load of vegetables when they have been washed with tap, chlorinated and ozonated water.

**Methods**

The methods which used for the bacteria are Health Protection Agency (HPA), ISO 11290-1:1996/Amd 1:2004, ELOT EN ISO 6579:2003/TC1:2004, Statutory Instrument SI 2383, 1989 and BS 4285:3.7. The part of the sensory analysis consists of a specific panel with ten people, who tasted and evaluated vegetables, after treated and washed with three treatments.

**Conclusions**

According to the results was proved that the region of origin probably is important for the surcharge of the microbiological load, but this is not affected by the sampling point. Ozonated water has the best performance for all samples for the microbiological control and sensory analysis. In general, broccoli have less Enterobacteriaceae load than lettuce.

**FEMS-0945**

**DETERMINATION OF KILLER ACTIVITIES OF THE YEAST STRAINS ISOLATED FROM NATURAL FERMENTATION MEDIA OF GEMLIK CULTIVAR BLACK OLIVES**

G. KARA<sup>1</sup>, Z.Y. ÖZBAŞ<sup>2</sup>

<sup>1</sup>Food Enginnering, Hitit University, Ankara, Turkey

<sup>2</sup>Food Enginnering, Hacettepe University, Ankara, Turkey

**Background**

Yeasts are common microorganisms present in spontaneous table olive fermentation. Killer yeasts secrete protein toxins that are lethal to sensitive strains. *Wickerhamomyces anomalus*, *Kluyveromyces marxianus*, *Pichia guilliermondii*, and *Saccharomyces cerevisiae* strains isolated from olive brines have been shown to produce killer toxins with a broad spectrum of activity against spoilage microorganisms of table olives. The killer characteristics of the yeasts have been applied to combat undesirable yeasts during the production of table olive.

**Objectives**

The aim of this study was to determine killer activities of the yeast strains isolated during natural fermentation process of 'Gemlik' cultivar olives grown in Akhisar and Iznik regions of Turkey. The effect of regional differences on killer yeast profile of Gemlik olives was also investigated.

**Methods**

A total of 54 endogenic yeast strains were investigated for killer activity. These were belonging to 7 genera as; *Candida*, *Aureobasidium*, *Debaryomyces*, *Cryptococcus*, *Kloeckera*, *Pichia* and *Clavispora*. Killer activity was detected by agar diffusion assay. In the method, two killers; *S.cerevisiae* NCYC 232 (K<sub>1</sub>), *S.cerevisiae* NCYC 738 (K<sub>2</sub>) and a sensitive strain; *S.cerevisiae* NCYC 1006 were used as reference yeasts.

**Conclusions**

From 54 strains, 40 were found as killer and 6 were killer-sensitive strains. Additionally, 8 strains were found to have neutral character. All *Debaryomyces hansenii*, *Pichia anomala*, *Clavispora lusitaniae* and *Kloeckera apiculata* strains were found as killer. No sensitive strain was found among the tested isolates. In conclusion, killer behavior of the endogenic yeast strains of Gemlik cultivar olives of Akhisar and Iznik regions was found as common characteristics.

**INVESTIGATION OF BRUCELLA SPP. AND BRUCELLA DNA IN RAW MILK  
OBTAINED FROM TRAKYA REGION, EDIRNE, TURKEY**

F. Kaynak Onurdağ<sup>1</sup>, S. Ökten<sup>1</sup>, B. Şen<sup>2</sup>

<sup>1</sup>Department of Pharmaceutical Microbiology, Trakya University Faculty of Pharmacy,  
Edirne, Turkey

<sup>2</sup>Department of Biology, Trakya University Faculty of Science, Edirne, Turkey

**Background**

Brucellosis is an important zoonotic disease transmitted to human by consuming contaminated milk and milk products. The prevention from Brucellosis is provided by live-attenuated vaccines for animals. Although Trakya is the pilot region in Turkey, for vaccination of animals, Brucellosis is endemoepidemic in this region. Thus, many dairy companies supply their milk from the cows grown in this region; screening of milks for *Brucella* contamination becomes very important.

**Objectives**

Our aim was to investigate *Brucella spp.* in milk, procured from Edirne and compare the conventional and molecular methods in terms of screening *Brucella spp.* in milk.

**Methods**

Milk samples from 99 cows at 12 different barns in 5 different villages of Edirne were collected. Bacteriological analyses and Q-PCR were applied to all samples. For samples that were culture negative and Q-PCR positive, a Q-PCR based method was evolved to differentiate the virulent and the vaccine strains.

**Conclusions**

In 2 of the 99 milk samples, *Brucella spp.* was isolated by bacteriological methods. After Q-PCR, *B. ovis* and *B. melitensis* were not detected, however, in 16 of the 99 samples *B. abortus* was detected. After the Q-PCR based method evolved to differentiate virulent and vaccine strains, only the 2 bacteriologically positive samples were detected to be positive.

As a result, it is reported that; 2.02% of the samples were detected to contain *Brucella*, both with the bacteriological method and PCR. It is also determined that, to obtain true positive results in *Brucella spp.* screening studies for milk, differentiating the virulent and vaccine strain should not be disregarded.

*<sup>2</sup>Food technology, Technological educational institute of peloponnese, Kalamata, Greece*

*<sup>3</sup>Laboratory for Protein Biochemistry and Biomolecular Engineering, Ghent University, Ghent, Belgium*

**Background**

Fermented dairy products are generally considered to be beneficial for human health as they contain live lactic acid bacteria frequently exhibiting biofunctional features. Here we present 55 lactic acid bacteria isolated from three traditional Greek yogurt samples and five fermented milk samples where their ability to produce bioactive peptides with inhibitory activity against the angiotensin-converting enzyme (ACE) was evaluated.

**Objectives**

The aim of this study is the potential of several lactic acid bacteria strains to be used as health promoting starter cultures with interesting technological features.

**Methods**

Strain typing was performed by rep-PCR, while 16S rDNA sequencing was used for the identification at the species level. The angiotensin-converting enzyme inhibitory (ACE-I) activity of the isolates was evaluated using a spectrophotometric assay with N-Hippuryl-His-Leu hydrate as substrate. Finally, a semi-preparative HPLC analysis was conducted using an ACE-5C18 column and positive fractions were subjected to MS analysis.

**Conclusions**

During this work 55 microorganisms have been isolated from traditional Greek yogurt and fermented milk samples. Strain typing by rep-PCR showed that the 33 isolated bacilli corresponded to 10 and the 22 cocci to 12 strain groups, respectively. The

strains did not show neither strong acidification capacity, nor peptidolytic activity and citrate metabolism, so their use as starter cultures does not seem suitable. Among them, many strains possessed interesting technological features as proteolysis and lipolysis and few exhibited high ACE-I activity. Purification of the ACE-I peptides was performed by RP-HPLC. These results indicate their potential use as adjunct or probiotic cultures.

## **EVALUATION OF CINNAMON AND MARJORAM ESSENTIAL OILS FOR THE CONTROL OF MYCOTOXIGENIC FUSARIUM SPECIES**

C. Gömörí<sup>1</sup>, E. Nacsá-Farkas<sup>1</sup>, E. Kerekes<sup>1</sup>, C. Vágvölgyi<sup>1</sup>, J. Krisch<sup>2</sup>

<sup>1</sup>Department of Microbiology, University of Szeged, Szeged, Hungary

<sup>2</sup>Institute of Food Engineering Faculty of Engineering, University of Szeged, Szeged, Hungary

### **Background**

*F. culmorum*, and *F. graminearum* are the most common causes of Fusarium ear blight of corn, wheat and other grains. Both of them produce the trichothecenes mycotoxins and *F. graminearum* also produces zearalenone.

### **Objectives**

The aim of this study was to evaluate the efficacy of cinnamon and marjoram essential oil (EOs) to control the growth of Fusarium species in vitro and to observe the changes of morphological characteristics of the fungi by SEM images after treatment with the oils.

### **Methods**

Colony growth inhibition effect of the EO vapors was investigated on the *Fusarium* species by the reversed Petri dish method using 0.070 mg/l, 0.14 mg/l, 0.28 mg/l and 0.56 mg/l EO/dish. The antifungal effect was measured by determination of growth-rate (mm/day) and antifungal index (%). MIC (minimal inhibitory concentration) and MFC (minimal fungicidal concentration) values were determined by agar dilution method. Morphological characteristics of the hyphae and micro conidia of *F. culmorum* were observed using a scanning electron microscope.

### **Conclusions**

Cinnamon EO vapor at 0.28 mg/l concentration caused total growth inhibition of all investigated species. Using marjoram EO vapor total inhibition was not detected, but growth-rates and colony diameters were reduced in each case. Agar dilution method was more effective to inhibit the growth of *F. culmorum* (MIC value =2.5 mg/ml). SEM imaging of *F. culmorum* showed that EO treated hyphae were thinner. Rupture of the cell wall and leakage of the cytoplasm contents were also observed. This study showed that EOs have potential antifungal effect against mycotoxigenic Fusarium species.

## **CHROMOHALOBACTER AS A CAUSATIVE AGENT OF THE PUTRESINE PRODUCTION DURING THE FERMENTATION OF GANJANG, KOREAN TRADITIONAL SOY SAUCE**

K. Kim<sup>1</sup>, J. Jung<sup>1</sup>, J. Jeon<sup>1</sup>

<sup>1</sup>life science, Chung-Ang university, Seoul, Korea

### **Background**

In fermented foods, the presence of biogenic amines (BAs), which were produced by microbial decarboxylase activity of microorganism, might serve as a useful indicator of food poisoning. Although BAs are also frequently found in ganjang, representative Korean traditional soy-sauce, there is no information about the BAs-producing microorganism in ganjang.

### **Objectives**

In this study, to investigate microorganism responsible for BAs production in ganjang, metabolite and bacterial community analysis were performed during entire fermentation process of ganjang.

### **Methods**

Ganjang with a NaCl concentration of approximately 18% (w/v) was prepared in one batch using traditional manufacturing method. The same amounts of ganjang were periodically sampled and their pH, NaCl concentration, and cell number were measured. <sup>1</sup>H NMR and PCR-DGGE were applied for analysis of metabolites and bacterial succession during the ganjang fermentation, respectively. In order to investigate the correlations among the ganjang samples, bacterial communities, and metabolites, a multivariate statistical redundancy analysis was performed using the vegan package of the R programming environment.

### **Conclusions**

Metabolite profiling and bacterial community analysis using a <sup>1</sup>H NMR and PCR-DGGE showed that a large amount of putrescine detected after 74 days of fermentation, which time begins to predominate the members of *Chromohalobacter*. A statistical analysis based on metabolite profiling and bacterial succession data clearly shows that members of *Chromohalobacter* are involved in the production of putrescine during ganjang fermentation. This study will allow for the successful understanding of the BAs-producing microorganism in ganjang.

**CHARACTERISTICS OF CONTAMINANT MICROBES IN COMPOUND FEEDS  
AND THE GROWTH INHIBITION EFFECT BY PROBIOTIC B. SUBTILIS**

S. Kim<sup>1</sup>, K.J. Yi<sup>1</sup>, J.S. Yeon<sup>1</sup>, D.W. Kim<sup>2</sup>

<sup>1</sup>*Department of Animal Science and Technology, Konkuk University, Seoul, Korea*

<sup>2</sup>*National Institute of Animal Science, RDA, Suwon, Korea*

**Background**

During long term storage of animal compound feed, contaminated microbes can grow with providing a problem of feed safety.

**Objectives**

The aim of this study was to investigate contaminant microbes and the effects of probiotic B. subtilis to inhibit them in animal feeds.

**Methods**

During storage of feed at room temperature, the changes of pH and titrable acidity were monitored with total microbial counts. Bacterial and fungal strains were isolated and tested for antibiotics resistance. Contaminated microbes were further identified by the sequencing of 16S and 18S rDNAs.

Probiotic B. subtilis was inoculated into both non-sterile and sterile feeds and tested for the growth inhibition of contaminated microbes during storage of feed at room temperature with pH change and probiotic viability.

**Conclusions**

Most contaminated microbes were originated from soil and plants. Sterile and non-sterile compound feeds displayed a different pattern of pH change. B. subtilis showed a normal growth and inhibited the cell growth of contaminant microbes.

**EVALUATION OF MICROBIAL CONTAMINATION LEVELS AT THE PRE- AND POST-GERMINATION STAGES ON SPROUTS.**

W. Kim<sup>1</sup>, S. Kim<sup>1</sup>, S. Ryu<sup>1</sup>, J. Ryu<sup>1</sup>, H. Kim<sup>1</sup>

<sup>1</sup>*Department of Crop Life Safety, National Academy of Agricultural Science, Wanju-gun, Korea*

**Background**

The consumption of raw sprouted seeds has led to a large number of outbreaks of foodborne illness in a great number of countries.

**Objectives**

The objective of this study was to investigate and evaluate microbial contamination levels of several kinds of sprouts in pre- and post-germination stage.

**Methods**

Fourteen kind of sprout seeds were purchased and analyzed. Quantitative analyses comprised aerobic plate counts (APCs) and the measurement of coliforms and *Bacillus cereus* levels, whereas qualitative analyses involved assessing the levels of *Escherichia coli* and major foodborne pathogens (*E. coli* O157:H7, *Listeria monocytogenes*, *Salmonella* spp. and *Staphylococcus aureus*).

**Conclusions**

The APCs ( $2.3\text{--}4.07 \log \text{CFU g}^{-1}$ ) for sprouts seeds increased by approximately 3-4  $\log \text{CFU g}^{-1}$  during germinating, reaching  $5.61\text{--}8.94 \log \text{CFU g}^{-1}$ . Similarly, increasing trends were noted in the level of *B. cereus* (N.D.- $2.62 \log \text{CFU g}^{-1}$  at the seed stage, increasing to N.D.- $3.14 \log \text{CFU g}^{-1}$  by the germinated stage). *E. coli*, *E. coli* O157:H7, *Salmonella* spp. and *L. monocytogenes* were not detected in the sprouts analyzed in this study. The present study provides comprehensive information regarding the microbiological safety of seeds and sprouts during manufacturing.

## **ANTIOXIDANT ACTIVITY OF FILAMENTOUS CYANOBACTERIAL STRAINS**

D. Kovač<sup>1</sup>, O. Babić<sup>1</sup>, M. Rašeta<sup>2</sup>, J. Simeunović<sup>1</sup>

<sup>1</sup>Department of Biology and Ecology, Faculty of Sciences-University of Novi Sad, Novi Sad, Serbia

<sup>2</sup>Department of Chemistry, Faculty of Sciences-University of Novi Sad, Novi Sad, Serbia

### **Background**

Antioxidants are compounds with role in food preservation, as well as in the prevention and treatment of some degenerative diseases. Despite their high amounts in plants, there is a growing interest for less conventional sources. Cyanobacteria, as a particular producers of bioactive compounds, represent an important source of antioxidants, which in terms of chemical structure include diverse compounds.

### **Objectives**

In the present study, the antioxidant capacity of three filamentous cyanobacterial strains belonging to the *Anabaena*, *Nostoc* and *Spirulina* genera have been tested. Furthermore, the content of C-phycocyanin, a pigment known as antioxidant compound was determined.

### **Methods**

The antioxidant capacity was tested using DPPH and FRAP assays. In DPPH assay, strains *Spirulina* S1 and *Anabaena* C5 showed similar IC<sub>50</sub> values of 118.47 µg/ml and 120.26 µg/ml respectively. In FRAP assay, the highest antioxidant activity was observed in *Spirulina* strain S1, ranging from 452.41 to 637.38 mg of ascorbic acid (AA) equivalent/gram of dry extract. The lowest antioxidant capacity expressed strain *Nostoc* 2S9B in both assays (IC<sub>25</sub> of 21.93 µg/ml, and 142.21-350.18 mg of AA equivalent/gram of dry extract).

The C-phycocyanin content was determined spectrophotometrically. The highest value of 38.63 µg/ml was detected in strain *Spirulina* S1, while lower contents were obtained in strains *Nostoc* 2S9B and *Anabaena* C5 (6.57 µg/ml and 9.34 µg/ml respectively).

### **Conclusions**

Since *Spirulina* strain S1 has expressed the highest antioxidant capacity in both assays, it could be further investigated as a potential source of antioxidants. High C-phycocyanin content found in this strain could be associated with its antioxidant activity.

Munster, Germany*

<sup>3</sup>*NBC-Detection,*

*Bundeswehr Research Institute for Protective Technologies and NBC Protection,  
Munster, Germany*

### **Background**

Securing the food chains from primary production to consumer-ready food against major deliberate, accidental or natural contaminations is directly related to the safety of food products. Spices and herbs are natural products of almost all processed food that can be contaminated with several microorganisms and toxins. The identification of those condiments would be difficult, as consumers and experts often focus on major food ingredients instead of minor components. Securing of spices and herbs commodity chains is the key issue within the EU FP7 project SPICED.

### **Objectives**

Characterization of the heterogeneous matrices and their respective production and supply chains in context with relevant biological hazards and the improvement of the knowledge on biological hazard properties as well as on-site and high throughput diagnostic methods for appropriate detection are main tasks.

### **Methods**

Within the SPICED project we mainly focusses on the toxins Ricin, which is the toxic component from castor beans of *Ricinus communis*, and the Enterotoxin-type B produced by the gram-positive bacteria *Staphylococcus aureus* (SEB). Their qualitative and quantitative detection in spices and herbs including the development of sample preparation methods were performed. For this purpose different types of spices and herbs were spiked with the toxins, stored at room temperature and analyzed e.g. with immunological based methods. Fieldable technologies and methods for the rapid on-site detection of toxins in the different were also examined.

### **Conclusions**

The intention is to present the recent results on the detection and sample preparation of the toxins from the spices and herbs with laboratory and field methods.

**EFFECT OF THERMALLY PROCESSED RICE KOJI EXTRACTS ON  
CHRONOLOGICAL LIFE SPAN OF SACCHAROMYCES CEREVISIAE ON HIGH-  
SUGAR FERMENTATION**

*C. Yamaoka<sup>1</sup>, O. Kurita<sup>1</sup>*

*<sup>1</sup>Food science, Mie Prefecture Industrial Research Institute, Tsu, Japan*

**Background**

Yeast cell growth and viability on high ethanol concentrations become limiting factors in fermentation productivity and ethanol yield. That is why measures to improve ethanol tolerance in yeast have been expected.

**Objectives**

**Fig. Transition of yeast populations (*S. cerevisiae* K-701) during fermentation in YNB20 medium with or without *koji* extracts (KE).**

**Different heat-processed (0, 15, and 30 min at 121°C) *koji* extracts were added at a final concentration of 10% (V/V). Fermentation was performed with the inoculation of precultures grown in YNB medium at 0.01 volume to each medium at 30°C.**

This study focused on *koji* as a material for sake brewing which provides nutrients for yeast cell growth. Our goal is to develop strategies for extending the life span of yeast by revealing the influence of heat-processed *koji* extracts on the survival of yeast under ethanol stress.

## Methods

Rice *koji* extracts were prepared by water extracts of dried rice *koji* heated at 60°C for 5 hrs. The *koji* extract was autoclaved for different times at 121°C. The availability of thermally processed rice *koji* extracts was investigated by analysis of ethanol tolerance and survivals on high-sugar fermentation in *S. cerevisiae* K-701 while making a comparison between heated and non-heated *koji* extracts.

## Conclusions

Addition of heat-processed *koji* extracts to high-sugar medium led to an improvement of chronological life span in *S. cerevisiae* K-701. The longer the heating time of *koji* extracts was, the higher the population of *S. cerevisiae* was during the late stationary phase. The Maillard reaction products which occurred in the heat-processed *koji* extracts had an explicit effect on the survivals of yeast under lethal ethanol stress. These show that heat-processed rice *koji* extracts were served as protectants of both ethanol and oxidative stresses when yeast cells became more oxidized in the stationary phase at higher ethanol concentrations.

**STUDY FOR INCREASING THE ANTIOXIDANT COMPOUNDS BY BACTERIA ISOLATED FROM FERMENTED FOOD**

K. Lee<sup>1</sup>, S. Lee<sup>1</sup>

<sup>1</sup>*Life science, Kyonggi University, Suwon, Korea*

**Introduction**

Oxidative stress arising from an imbalance in the human antioxidant status, reactive oxygen species vs. defense and repair mechanisms, is mainly responsible for the development of pathological disease. Phenolic compounds in safflower seeds are receiving much attention as potential therapeutic agents against several pathological diseases. The antioxidant properties of safflower seeds is matairesinol 4'-o- $\beta$ -D-glucose, 8'-hydroxyarctigenin 4'-o- $\beta$ -D-glucose, matairesinol, 8'-hydroxyarctigenin, N-feruloylserotonin 5-o- $\beta$ -D glucoside, N-(p-coumaroyl)-serotonin-5-o- $\beta$ -D-glucoside, N-feruloylserotonin, N-(p-coumaroyl)serotonin, luteolin 7-o- $\beta$ -D-glucoside, luteolin, acacetin 7-o- $\beta$ -D-glucuronide, and acacetin.

**Objective.**

In our experiment, bacteria isolated from ginger fermented food were used to make phenolic compound from aglycon. It makes to increase antioxidant activity of safflower seeds.

**Methods**

Fermented samples were got from one of the member of Korea royal cuisine institute. Fermented sample was inoculated in tryptic soy broth media and incubated 28°C for 48h. After bacteria grow, bacteria were centrifuged 6000rpm at 4°C for 20 min. Bacteria were dissolved 60ml mineral salt media (MSM) (20g/L) and mixed with 30g safflower seed. Each bottle was incubated 28°C for one week.

For phenolic compound extraction, each safflower seed mixed with bacteria was sonicated in hexane for 30min twice and filtered. The defatted seed residue was extracted twice with 70% EtOH under sonication, filtered and evaporated under reduced pressure. The extract was used for HPLC and GC-MS and DPPH activity.

**Conclusion**

This study was to evaluate the antioxidant activity in safflower seeds after fermentation. Bacteria that improved antioxidant activity in safflower seeds after fermentation was identified Sphingomons sp using 16s rRNA sequencing. Safflower seed was improved antioxidant activity from 7.11% to 51% after 5 days. In HPLC analysis, Major peak of safflower seed extracts after fermentation was changed after 5 days under aerobic condition at 30°C. Furthermore analysis, we will conduct to investigate which compound in the safflower seed will be changed to phenolic compound for increasing antioxidant activity.

## **EFFECTS OF SEED TREATMENT BY COLD ATMOSPHERIC PLASMA ON CUCUMBER SEEDLING GROWTH**

Y. Lee<sup>1</sup>, Y. Kim<sup>2</sup>, Y. Jeon<sup>2</sup>

<sup>1</sup>*Biology, Andong National University, Andong-si, Korea*

<sup>2</sup>*Bioresource Sciences, Andong National University, Andong-si, Korea*

### **Background**

Cold atmospheric plasma can have different effects on seed germination and seedling growth depending on the plasma frequency, the power and its environmental conditions.

### **Objectives**

Cold plasmas are already well-known for their improvement effect on plant growth. However, the mechanisms of this ability are unclear.

### **Methods**

Non-thermal atmospheric-pressure DBD plasma in He was applied with different exposure times on cucumber seed. Changes in the seed surface with different exposure time were examined by scanning electron microscope (SEM). Direct and indirect influence on cucumber seed of the cold plasma is compared in terms of seedling growth.

### **Conclusions**

Germination and early seedling growth of cucumber were improved by the plasma treatment for 6 second. In contrast, the seeds exposed for 10 minutes were not germinated. In 6 sec treatment and no treatment control, gold nanoparticles were observed along the cell wall. There were no particles observed in the 10 min treatment. It suggests that no tissue damage is observed visually or microscopically following 6 sec and control, but the rough surface of seeds were smooth and damaged at long exposure time (10 min). We observed that the indirect method had more enhanced effect on growth than direct method. This infers to an important conclusion that the effect of plasma on improved growth of seedlings is due to various plasma components that can exist inside or outside the plasma region not mechanical power such as an abrasion of seed surface.

**Food microbiology**

## **METABOLICALLY ACTIVE BACTERIA IN LYMPHATIC TISSUES OF PIGS AND ITS SPREAD DURING SLAUGHTER**

E. Mann<sup>1</sup>, M. Wagner<sup>1</sup>, S. Schmitz-Esser<sup>1</sup>

<sup>1</sup>Department for Farm Animals and Veterinary Public Health,  
Institute for milk hygiene milk technology and food science, Vienna, Austria

### **Background**

The occurrence of potential food-borne pathogenic organisms in lymphatic tissues of farm animals has practical relevance for carcass contamination. A transmission of pathogens, which can occur from harvesting until the last step in the meat-processing chain, remains the preeminent difficulty in slaughter house hygiene.

### **Objectives**

The aims of this study were i.) to evaluate the contamination degree of porcine cervical musculature during slaughter, ii.) to compare the bacterial microbial community detected by DNA-based amplicon sequencing with RNA-based amplicon sequencing and thus measuring the fraction of metabolically active bacteria in lymphatic tissues.

### **Methods**

Mandibular lymph nodes, tonsils and scrapings from cervical musculature were sampled from eight healthy slaughter pigs derived from different farmers. RNA was isolated from lymph node cortex regions and tonsils (n=16) and DNA was isolated from cervical musculature (n=8). Total RNA was transcribed into cDNA and all samples were sequenced with Roche/454 using 16S rRNA gene amplicons.

### **Conclusions**

Organisms relevant for food safety, e.g. *Erysipelothrix*, *Listeria*, *Escherichia* and *Pseudomonas*, could be detected in lymphatic tissues. RNA-based amplicon sequencing revealed a highly diverse, metabolically active bacterial microbiome in mandibular lymph nodes and tonsils; consisting of 348 and 390 operational taxonomic units (OTUs) respectively (30% shared OTUs). The functional metagenome prediction (PICRUSt) and subsequent assignments of orthologues to COG categories revealed amino acid transport and metabolism- related orthologues being increased in lymph nodes compared to tonsils. Both, mandibular lymph nodes and tonsils of slaughter pigs harbor a replication-competent bacterial microbiome indicating a possible contamination source during and after slaughter.

**Food microbiology**

## **ISOLATION AND CHARACTERIZATION OF THE MICROFLORA PRESENT IN A MINIMALLY PROCESSED VEGETABLES PLANT**

A. Meireles<sup>1</sup>, R. Fulgêncio<sup>1</sup>, F. Mergulhão<sup>1</sup>, L. Melo<sup>1</sup>, M. Simões<sup>1</sup>

<sup>1</sup>Chemical Engineering Department,

LEPABE - Faculty of Engineering of University of Porto, Porto, Portugal

### **Background**

Food safety is an area of growing concern due to the increasing demand for microbiologically safe products. Additionally, disinfection techniques must evolve to cope with the development of antimicrobial resistance. An efficient disinfection strategy must consider the type of microbial contaminant. Therefore, the knowledge on the microorganisms present in an industrial process is crucial to define the best strategy for their control.

### **Objectives**

The aims of the present work were to isolate and characterize the resident microflora present in a minimally processed vegetables (MPV) plant.

### **Methods**

The microorganisms were isolated from a MPV plant process surfaces by cotton swabbing, from the air and from the vegetable surfaces. The isolates were identified by 16S rRNA gene sequencing with 4 primers: 27F, 518F, 800R e 1492R. The isolates were also characterized for their production of proteases, gelatinases and siderophores, quorum-sensing inhibition and biofilm formation ability.

### **Conclusions**

From 50 different isolates 46% belong to the *Pseudomonas* genera and 22 were from different species. Some microorganisms persisted along the food chain, which means that the cleaning process should be targeted for the more resistant microorganisms. Most of the microbial isolates are capable of producing virulence and food spoilage molecules. Moreover, *Pseudomonas* were the genera with a higher biofilm formation ability, being the predominant microflora and showing recalcitrant properties along the process chain.

**TECHNOLOGY, BIOCHEMICAL AND MICROBIOLOGICAL FEATURES  
INFLUENCING THE CONCENTRATION OF BIOGENIC AMINES OF TWENTY  
APULIAN AND SICILIAN (SOUTHERN ITALY) CHEESES**

*R. Guarcello<sup>1</sup>, A. Diviccaro<sup>2</sup>, M. Barbera<sup>1</sup>, E. Giancippol<sup>2</sup>, L. Settanni<sup>1</sup>, F. Minervin<sup>2</sup>,  
G. Moschetti<sup>1</sup>, M. Gobbetti<sup>2</sup>*

*<sup>1</sup>Scienze Agrarie e Forestali, Università degli Studi di Palermo, Palermo, Italy*

*<sup>2</sup>Scienze del Suolo della Pianta e degli Alimenti,  
Università degli Studi di Bari Aldo Moro, Bari, Italy*

**Background**

Biogenic amines (BA) are low-molecular nitrogenous organic bases, which are formed in foodstuffs by microbial decarboxylation of the precursor amino acids and are potentially toxic to human health. Cheeses are among the foods most commonly associated with the presence of BA (1). Concentration of BA results from a balance between amino acid decarboxylating and amine oxidising activities.

**Objectives**

To correlate the content of BA of twenty traditional Apulian or Sicilian (Southern Italy) cheeses with several technology and microbiological features such as time of ripening, pH, concentration of precursor free amino acids (FAA), and occurrence of decarboxylase-positive lactic acid bacteria.

**Methods**

Cheeses were analysed through plate counting and HPLC, and lactic acid bacteria isolated from cheeses were assayed (by decarboxylase medium) for their capacity to generate BA. Principal Component Analysis was performed to find the effect of different parameters on the distribution of the cheeses.

**Conclusions**

Although short-ripened cheeses did not show significant BA concentrations, the only BA showing high positive correlation with time of ripening was histamine. Concentration of histidine and, especially, percentage of histidine-decarboxylase bacteria presumably affected histamine concentration. High pH values were negatively correlated to the concentration of tyramine, putrescine, and cadaverine (Fig. 1). Fifty percent of the cheeses contained at least one BA at potentially toxic concentrations. Unambiguous and ever-valid relations among parameters and BA are difficult to determine, because BA are the result of combined and varied factors.

## **DYNAMICS OF BACTERIAL COMMUNITIES DURING THE RIPENING PROCESS OF CROATIAN RAW EWE'S MILK CHEESE**

M. Mrkonjić Fuka<sup>1</sup>, S. Wallisch<sup>2</sup>, M. Engel<sup>2</sup>, M. Schlöter<sup>2</sup>

<sup>1</sup>Department of microbiology, University of Zagreb Faculty of Agriculture, Zagreb, Croatia

<sup>2</sup>Research Unit for Environmental Genomics, Helmholtz Zentrum München, Neuherberg, Germany

### **Background**

Croatian raw ewe's milk cheeses are hard cheeses that are produced by traditional techniques without pasteurization and application of starter cultures, and they are characterized by an aging process of 90-120 days. This aging time is rather long and the low pH and water activity ( $a_w$ ) of ripened cheese usually does not support the growth of pathogens. However, due to the commercial pressure, the ripening time has been shortened and it has become market practice to sell the cheese as soon as possible.

### **Objectives**

A close monitoring of bacterial communities and a reliable identification of indigenous microflora is crucial in order to maintain the quality and safety of artisan cheese.

### **Methods**

Cheese samples of three cheese types (0, 45 and 90 days of ripening) were collected from 6 cheese makers. Total DNA was extracted and microbial diversity was investigated based on fingerprinting in combination with next generation sequencing of 16S rRNA gene amplicons.

### **Conclusions**

Overall up to 213 OTU<sub>97</sub> could be assigned. Twenty of the major OTUs were present in all samples and include mostly LAB, mainly *Lactococcus* and *Enterococcus* species. Abundance and diversity of these genera differed to a large extent between the 3 investigated cheese types and in response to the ripening process. Also a large number of non LAB genera could be identified based on phylogenetic alignments including mainly *Enterobacteriaceae* and *Staphylococcaceae*. Some species belonging to these two families could be clearly assigned to species which are known as potential human pathogens. However, during cheese ripening their abundance was reduced.

**TRACKING OF PATHOGENIC AND BENEFICIAL MICROFLORA FROM WILD BOAR MEAT SAUSAGES TRADITIONALLY PRODUCED IN CROATIA**

M. Mrkonjić Fuka<sup>1</sup>, M. Zunabović<sup>2</sup>, S. Mayrhofer<sup>2</sup>, A. Žgomba Maksimović<sup>1</sup>,  
M. David<sup>2</sup>, K. Domig<sup>2</sup>

<sup>1</sup>Department of microbiology, University of Zagreb Faculty of Agriculture, Zagreb, Croatia

<sup>2</sup>Dept. of Food Science and Technology,  
BOKU - University of Natural Resources and Life Sciences Institute of Food Science,  
Vienna, Austria

**Background**

Sausages from game meat produced by traditional procedures by small scale producers in Croatia do not include the application of starter cultures. Such artisan products are increasingly appreciated because of their sensory properties and authenticity, although considerations regarding their microbiological safety are existent.

**Objectives**

An in depth analysis and characterization of the indigenous microflora of traditionally produced wild boar meat sausages from Croatia is needed in order to estimate microbiological hazards and to preserve an indigenous microbial pool.

**Methods**

Traditionally produced wild boar sausages were collected from three farms during ripening (0, 2, 4, 7, 10, 20 and 40 days) and analyzed for spoilage and pathogenic microflora (*L. monocytogenes*, *Salmonella* spp., total *Enterobacteriaceae*, coliforms, yeasts and molds, *B. cereus* group and coagulase-positive staphylococci) as well as for beneficial microbes e.g. lactic acid bacteria (LAB) and coagulase-negative staphylococci (CNS). Genomic DNA was extracted from 720 LAB and CNS isolates. After RAPD and rep-PCR based grouping identification was done by PCR and partly 16S rRNA gene sequencing.

**Conclusions**

A remarkable diversity was found among the investigated LAB and CNS populations of which several isolates relevant for sausage ripening and product quality were identified as e.g. *Lactobacillus sakei*, *Leuconostoc mesenteroides*, *Staphylococcus xylosus*, *Staphylococcus saprophyticus* and *Staphylococcus warneri*. Although some spoilage and pathogenic microflora were present at the initial stages of sausages' ripening, they were absent in the ripened "ready to eat" sausage.

## **REDUCING THE RISK OF BABY LEAF SURFACE BACTERIA WITH IRRIGATION RESTRICTIONS**

L. Mogren<sup>1</sup>, N. Hooshang<sup>1</sup>, M. Alam<sup>2</sup>, B. Alsanius<sup>1</sup>

<sup>1</sup>Dep of Biosystems and Technology,

Swedish University of Agricultural Sciences (SLU), Alnarp, Sweden

<sup>2</sup>Dep of Horticulture, The University of Agriculture, Peshawar, Pakistan

### **Background**

Baby leaf crops like Spinach (*Spinacia oleracea*), Chard (*Beta vulgaris*) and Rocket (*Diplotaxis tenuifolia*) are grown on huge open space flat fields in Sweden. It is hard to stop birds and wild animals to visit the field with related risks of E. coli infections. But as a grower, one can make sure the irrigation water doesn't act as a bacteria vector.

### **Objectives**

The main objective of this study was to reduce the risk of E. coli bacteria reaching baby leaf crops during crop growth in field, thereby reducing the risk of food borne diseases further down the delivery chain.

### **Methods**

Leaves were grown with more or less constant optimal wet conditions in the root zone (irrigation water given up to field capacity every other day) or with restricted irrigation (drought conditions) in the final part of the growth period. 24 hours prior to harvest plants were sprayed with a known quantity of E. coli. Harvested leaves were put in a stomacher and the leaf rinsates plated on agar and the colonies counted and compared to non-sprayed leaves.

### **Conclusions**

Irrigation restriction only had minor impact on E. coli colonization on the leaf surface. The yield and quality was significantly reduced and the content of bioactive compounds affected. The main conclusion is that drought stress during the final part of baby leaf production is not to recommend and as a way to reduce the risk of food borne diseases caused by baby leaf salads.

## **IMPROVED DETECTION OF ESCHERICHIA COLI AND COLIFORM BACTERIA BY MULTIPLEX PCR**

F. Molina<sup>1</sup>, E. López-Acedo<sup>1</sup>, J.E. Rebollo<sup>1</sup>, A. Simancas<sup>1</sup>, R. Tabla<sup>2</sup>, I. Roa<sup>2</sup>, A. Gómez<sup>2</sup>

<sup>1</sup>Genetics, Universidad de Extremadura, Badajoz, Spain

<sup>2</sup>Dairy products, Technological institute of Food and Agriculture, Badajoz, Spain

### **Background**

The presence of coliform bacteria is routinely assessed to establish the microbiological safety of water supplies and raw or processed foods. Coliforms are a group of lactose-fermenting *Enterobacteriaceae*, which most likely acquired the *lacZ* gene by horizontal transfer and therefore constitute a polyphyletic group. Among this group of bacteria is *Escherichia coli*, the pathogen that is most frequently associated with foodborne disease outbreaks and is often identified by  $\beta$ -glucuronidase enzymatic activity or by the redundant detection of *uidA* by PCR.

### **Objectives**

Because a significant fraction of essential *E. coli* genes are preserved throughout the bacterial kingdom, alternative oligonucleotide primers for specific *E. coli* detection are not easily identified.

### **Methods**

Here two strategies were used to design oligonucleotide primers with differing levels of specificity for the simultaneous detection of total coliforms and *E. coli* by multiplex PCR. A *lacZ* sequence and an orphan gene were chosen as targets for amplification.

### **Conclusions**

A comparison with previously described primers indicates an increase in identification efficacy when tested with laboratory collection and lactose-fermenting strains isolated from dairy samples. While *lacZ* amplicons were found in a wide range of lactose-fermenting strains, amplification using the selected orphan gene was highly specific for *E. coli*. Additionally, the detection of this target sequence is non-redundant with enzymatic methods.

**EFFECT OF OXYGEN CONCENTRATION AND GAS PRESSURE ON THE GROWTH OF ARTHROSPIRA SP. PCC 8005**

J. García<sup>1</sup>, H. Moors<sup>1</sup>, I. Tejero<sup>2</sup>, N. Leys<sup>1</sup>

<sup>1</sup>Microbiology, SCK•CEN, Mol, Belgium

<sup>2</sup>Sciences and Techniques in Water and Environment, University of Cantabria, Santander, Spain

**Background**

The MELiSSA project of the European Space Agency, ESA, aims to create a bio-regenerative life support system for long term space travels. One of its bioreactors contains *Arthrospira* sp. PCC 8005, an edible cyanobacteria that can remove CO<sub>2</sub> and provide O<sub>2</sub>. Normal operating conditions will likely enhance oxygen concentration and gas pressure buildup.

**Objectives**

The objective of this study is to elucidate the impact of oxygen concentration and gas pressure on the duration of the lag phase, the specific growth rate and the maximum number of attained generations in a batch culture of *Arthrospira* sp. PCC 8005.

**Methods**

Cultures of *Arthrospira* sp. PCC 8005 were grown in 100 ml closed septum vials with Zarrouk-UBP medium, at 30 °C with 32 µE m<sup>-2</sup> s<sup>-1</sup> of irradiance and shaken at 130 rpm. Growth was monitored measuring OD<sub>750nm</sub>. Produced oxygen was accumulated. Oxygen tests were done with an initial 100% oxygen gas phase, in comparison to 100% argon, both at initial 1 bar. Pressure tests were done at 1, 2 and 3 bars of starting absolute pressure in 100% argon. Growth parameters were calculated using a modified Gompertz function. Statistical analysis was performed with 95% confidence interval T-Test.

**Conclusions**

The oxygen concentration has only a limited but statistically significant effect on the growth rate. Growth tests at elevated pressures of up to 3 bar had no effect on neither growth parameter. Test results at elevated pressures with 100% oxygen pressures, are expected to prove and further quantify the inhibitory effect of oxygen on the growth.

**DETECTION OF ITURIN AND FENGYCIN BY MALDI-TOF IN FOOD MATRIX OF PUBA, A STAPLE BRAZILIAN FERMENTED FOOD**

R. Nardi<sup>1</sup>, K.J. Perez<sup>1</sup>, D.M. Santos<sup>2</sup>, J.S. Viana<sup>1</sup>

<sup>1</sup>*Microbiology, Biological Sciences Institute, Belo Horizonte, Brazil*

<sup>2</sup>*Biochemistry and Immunology, Biological Sciences Institute, Belo Horizonte, Brazil*

**Background**

*Puba* or *carimã* is a Brazilian staple food obtained by spontaneous submerged fermentation of cassava (*Manihot esculenta*, Crantz) roots. Traditional fermentation of cassava is predominantly performed by lactic acid bacteria, but yeasts and *Bacillus* spp. were also found in our sample.

**Objectives**

To investigate the production of lipopeptides by *Bacillus* sp. P5 isolated from *puba* in the culture medium and in *puba* matrix by MALDI-TOF.

**Methods**

In a previous study, 16S rRNA of *Bacillus* sp. P5, isolated from *puba*, was sequenced. The phylogenetic analyses showed recovery in a node with 92% of support with *B. amyloliquefaciens*. The culture supernatant was subjected to extraction with n-butanol (Landy medium) purification by reversed-phase HPLC (C18 column) and MALDI-TOF mass spectrometry analysis. Surfactins, iturins and fengycins were detected. To investigate the production of lipopeptides by *Bacillus* sp. P5 isolated from *puba* in the culture medium and in *puba* matrix by MALDI-TOF. An aqueous suspension of *puba* was extracted with butanol and concentrated in Zip Tip® C18. Molecular mass was determined by MALDI-TOF. Data were acquired in the mass range m/z 1,000-4,000 for the butanol extract. The results are shown in Figure 1. Two clusters were found: iturin and fengycin (Fgy) (1A). Expansion of the spectrogram of Fgy indicated protonated ion and sodium and potassium adducts (1B), and in (C) MS/MS spectrum of precursor ion of m/z 1478.5 (Fgy C<sub>17</sub>) which generated fingerprints of fgy A.

## Conclusions

In conclusion, *puba* is manufactured in an unhygienic environment, and iturin and fengycin exhibit biocontrol properties that are probably important for the safety of this product.

**BACTERIAL ASSESSMENT OF FOOD - HANDLERS IN SARI CITY AND ITS SUBURB , MAZANDARAN PROVINCE, NORTH OF IRAN.**

M. Nasrolahei<sup>1</sup>, M. Vahedi<sup>1</sup>, M. Salehian<sup>1</sup>, F. Fakhraei<sup>1</sup>, M. Kholdi<sup>1</sup>

<sup>1</sup>Microbiology, Mazandaran University Of Medical Sciences, Sari, Iran

**Background**

Diarrheal diseases, mostly caused by food borne or waterborne microbial pathogens, are leading causes of illness and deaths in developing countries, killing an estimated 1.9 million people annually at the global level.

**Objectives**

This study was designed to determine the prevalence of carriers of pathogenic bacteria among the food-handlers employed at food service facilities in Sari city and its suburbs, Mazandaran Province, Iran

**Methods**

Of the total subjects examined, 62.2 % were found to be carriers of some pathogenic bacteria.

The pathogens isolated and identified were the bacteria *Staphylococcus aureus*, *shigella sonnei* and *pseudomonas aeroginosa*.

Fast food makers were the greatest prevalence of bacteria in respect of their fingernail contents (86.6 %,  $p=0.04$ ) followed by butchers (76.4%), storekeepers (73%), bakers (58.3%) and restaurant workers (51.5 %). *Staphylococcus aureus* was the predominant bacteria isolated from nail-washing samples (45.9%), followed by *Escherichia coli* (28.4%), *coliform* (18.2%) and *Pseudomonas aeroginosa* (6.5%),

Illiterate food-handlers had the highest percentage of positive cultures from nail-washing specimens (86.8%,  $p= 0.0005$ ) and the lowest rate of infestation was among university educated subjects (33.3 %).

The rate of of *Staphylococcus aureus* nasal carrier among food-handlers was 18.6 % with the highest rate among store-keepers (31.7%) followed by bakers (24.3%), restaurant workers (19.5%), butchers (14.6%) and fast-food makers (9.7%). *Shigella sonnei* were isolated from stool samples of two food-handlers (0.9%).

**Conclusions**

The finding emphasized the importance of food-handlers as potential sources of infections. A medical check –up program with health education could improve worker's health status.

## **ISOLATION AND MOLECULAR IDENTIFICATION OF LACTIC ACID BACTERIA FROM DONKEY MILK**

F. Nazarian-Firouzabadi<sup>1</sup>, M.J. Akrami<sup>1</sup>, M. Bagheri<sup>1</sup>, A. Ismaili<sup>1</sup>

<sup>1</sup>Agronomy and Plant Breeding Department, Lorestan University, Khorramabad, Iran

### **Background**

Lactic acid bacteria (LAB) are living organisms that play a major role in many food and dairy products as a probiotics. Donkey's milk is being used as a source of human nutrition, especially for infants with allergy to cow milk proteins, due to its antimicrobial components, many defense factors and probiotic properties. Few studies have so far dealt with the microbiota in donkey's milk, specifically lactic acid bacteria (LAB) diversity.

### **Objectives**

This study was undertaken to identify the microfora of LAB in donkey's milk in IRAN.

### **Methods**

The culture-dependent microbial and 16S rRNA sequencing techniques were used to identify lactic acid bacteria species in donkey milk. A total of 250 LABs from donkey milk were assessed by culture-dependent microbial tests, including culture at different temperatures, pH and Multiple antibiotic resistance indexing.

### **Conclusions**

*Enterococcus faecalis* (55%) and *Streptococcus devriesei* (45%) were the most prevalent species in donkey milk. No other LAB belonging to the most technically important genera was identified. Biochemical and sugar fermenting analyses confirmed the results of 16S rRNA sequencing. Both species identified were sensitive to nearly all antibiotic tested, including vancomycin. Few strains were found to have >99% sequence similarity with *Streptococcus devriesei*, indicating the presence of this LAB in donkey milk. This is the first study to investigate the LAB microbiota present in donkey's milk in IRAN.

**BIOGEOGRAPHY OF NON-SACCHAROMYCES YEASTS ASSOCIATED WITH SPONTANEOUSLY FERMENTED MUSTS FROM DIFFERENT VINEYARDS AND WINE PRODUCING REGIONS IN GREECE**

*D. Dourou*<sup>1</sup>, *M.E. Filippousi*<sup>1</sup>, *E. Gyftogianni*<sup>1</sup>, *C. Tassou*<sup>1</sup>, *G. Banilas*<sup>2</sup>, *A. Nisiotou*<sup>1</sup>

<sup>1</sup>*ELGO, Institute of Technology of Agricultural Products, Athens, Greece*

<sup>2</sup>*Department of Enology, TEI of Athens, Athens, Greece*

**Background**

Non-*Saccharomyces* (wild) yeasts may confer diverse chemical composition and improved sensory properties to wines. Yet, our knowledge on population structure of these species is limited.

**Objectives**

Species diversity and population structure of 486 wild yeasts associated with spontaneously fermented musts from two geographically separated regions in Greece, Peza and Nemea, were assessed. The efficiency of different fingerprinting methods in resolving yeast populations was evaluated.

**Methods**

Species identification was conducted by PCR-RFLP analysis. For molecular typing the tandem repeat-tRNA (TRtRNA)-PCR and RAPD analysis with primers (GTG)<sub>3</sub>, R<sub>5</sub> or RF<sub>2</sub> were applied. Molecular patterns and vineyard populations were clustered by Principal Coordinates Analysis and UPGMA, respectively. Differences of populations were evaluated by analysis of molecular variance (AMOVA).

**Conclusions**

Ten populations of wild species were identified and further genotyped by TRtRNA-PCR with the primer ISSR-MB (*Lachancea thermotolerans*, *Metschnikowia pulcherrima* and *Hanseniaspora osmophila*), and RAPD with the primer RF<sub>2</sub> (*Candida zemplinina*), (GTG)<sub>3</sub> (*Hanseniaspora uvarum* and *Hyphopichia pseudoburtonii*) or R<sub>5</sub> (*Issatchenkia orientalis*, *Pichia anomala*, *Torulaspora delbrueckii*, and *Hanseniaspora guilliermondii*). Except for *I. orientalis*, the percentage of biodiversity of yeast populations was higher in Nemea than in Peza. No particular grouping of banding patterns according to the sampling point or to the vineyard of origin was observed.

However, AMOVA showed that populations of *C. zemplinina* and *L. thermotolerans* differed significantly between the two regions. Results point to the presence of region specific sub-populations of non-*Saccharomyces* yeasts species that could enhance the Greek wines distinctiveness.

## **SELECTION OF INDIGENOUS YEASTS FOR PRODUCTION OF QUALITY TERROIR-DRIVEN GREEK WINES**

*E. Diamantea*<sup>1</sup>, *D. Dourou*<sup>1</sup>, *G. Banilas*<sup>2</sup>, *A. Nisiotou*<sup>1</sup>

<sup>1</sup>ELGO, Institute of Technology of Agricultural Products, Athens, Greece

<sup>2</sup>Department of Enology, TEI of Athens, Athens, Greece

### **Background**

According to the microbial *terroir* concept, the use of indigenous yeasts as starters in winemaking may add to the uniqueness of regional wines.

### **Objectives**

Genetically different yeast strains from spontaneously fermented musts from Santorini island, Mantinea plateau and Nemea region were characterized phenotypically in order to select strains with desirable enological properties to be used as starters.

### **Methods**

Strains belonging to *Candida zemplinina*, *Issatchenkia orientalis*, *Hanseniaspora quilliermondii*, *H. opuntiae*, *Lachancea thermotolerans*, *Saccharomyces cerevisiae* and *Torulaspora delbrueckii* were evaluated for tolerance to ethanol, SO<sub>2</sub> and different temperatures, H<sub>2</sub>S and biogenic amines production, maximum population size, foam generation, killer and flocculation phenotype.

### **Conclusions**

Most of *S. cerevisiae* strains tolerated the selective pressures assayed, exhibiting growth at 16% ethanol, 250 ppm SO<sub>2</sub> or 37 °C. Lower tolerance limits were observed for non-*Saccharomyces* yeasts, with strains of *C. zemplinina*, *I. orientalis* and *T. delbrueckii* growing well at concentrations of 14% ethanol or 200 ppm SO<sub>2</sub>. Most strains did not produce histamine, tyramine, putrescine, cadaverine phenylethylamine, tryptamine and isoamylamine, presented low foaming, no-flocculation or killer phenotype and were resistant to killer toxins. Substantial intra- and inter-species differences were observed in H<sub>2</sub>S production. Present results highlight the phenotypic diversity among indigenous yeasts and reveal strains with prominent oenological traits that could be exploited in local wine production.

### **Acknowledgements**

This work has been co-financed by the European Regional Development Fund (ERDF) of the EU and by National Resources under the Operational Program Competitiveness and Entrepreneurship (EPAN II), Action "COOPERATION 2011".

## **DEVELOPMENT AND EVALUATION OF YOGHURT FLAVOURED WITH TAMARIND (TAMARINDUS INDICA)**

I. Nwaoha<sup>1</sup>, B. Ibanga<sup>1</sup>

<sup>1</sup>Department of Food Science and Technology,  
University of Nigeria Nsukka Enugu State, Nsukka, Nigeria

### **Background**

Yoghurt is produced by bacterial fermentation of milk sugar (lactose), using *Streptococcus thermophilus* and *Lactobacillus bulgaricus*, producing lactic acid give yoghurt its texture and its characteristic tang. To modify certain properties of yoghurt, the fermented milk could be blended with ingredients fruits (for flavor and color) and sucrose or aspartame (sweetness). Exotic natural or artificial flavors to boost yoghurt like vanilla, orange, pineapple, strawberry, raspberry, cinnamon among others. However, tropical underutilized flavours like tamarind (*Tamarindus indica*) have not been exploited.

### **Objectives**

To develop and evaluate yoghurt flavored with Tamarind chemically, microbiologically and organoleptically.

### **Methods**

Tamarind fruit was pulped to juice and treated in three ways (sweetened with sugar, honey or without sweetener/ Skimmed milk and water are homogenized, pasteurized for 15 mins at 85°C, and cooled to 42 - 44°C. The starter culture inoculated, mixed and incubated for 12 hour fermentation, flavoured with graded levels (0, 2, 4, 6, 8, 10, 20, 30, 40, 50 %.) of tamarind juice and stored for 0 to 21 days with weekly monitoring. The sample was then subjected to proximate, micro-nutrient, microbiological and sensory analysis.

### **Conclusions**

Micro-nutrient content (Mg, Na, K, C and Vitamin C) increased with the addition of the fruit juice. Total solids increased with increase concentration of the sweetened fruit flavour in yoghurt. There was no mould or coliform growth but the total viable count ranged from  $6.3 \times 10^2$  to  $2.34 \times 10^7$  cfu/ml after 21 days. The sugar sweetened samples were most acceptable over the honey and fruit juice without sweetener.

## **HIGH-THROUGHPUT SEQUENCING REVEALS BIOGENIC AMINE FORMING COMMUNITIES IN A VARIETY OF ARTISANAL CHEESES**

D.J. O'Sullivan<sup>1</sup>, P.D. Cotter<sup>1</sup>, V. Fallico<sup>1</sup>, P.L.H. McSweeney<sup>2</sup>, L. Giblin<sup>1</sup>, J.J. Sheehan<sup>3</sup>

<sup>1</sup>Food Biosciences, Teagasc Food Research Centre, Cork, Ireland

<sup>2</sup>Food and Nutritional Sciences, University College Cork, Cork, Ireland

<sup>3</sup>Food Science and Technology, Teagasc Food Research Centre, Cork, Ireland

### **Background**

Biogenic amines are nitrogenous compounds with biological activity produced, primarily, by a variety of lactic acid bacteria. Biogenic amines, such as histamine and tyramine, are commonly found in fermented food products. In cheese, high concentrations can result in adverse health effects for the consumer.

### **Objectives**

The aim of this study was to screen a range of artisanal cheeses (n=10) for the presence of microbial populations capable of producing biogenic amines.

### **Methods**

Segments of the histidine (*hdc*) and tyrosine (*tdc*) decarboxylase genes were amplified using previously published PCR primer pairs. PCR amplicons were then TOPO-cloned and subjected to Sanger sequencing. In addition, the Ion Torrent PGM sequencer was used to provide a novel, complementary, in depth analysis of amine forming communities.

### **Conclusions**

Analysis of both Sanger and Ion PGM sequence data revealed *hdc* and *tdc* positive bacterial populations both within cheeses and across different cheese varieties. *Lactobacillus curvatus*, *Lb. brevis*, *Enterococcus faecium* and *E. faecalis* were identified as the predominant species capable of producing tyramine while *Lb. buchneri*, *Lb. sakei* and *Lactococcus lactis* were among the species found to harbour histaminogenic potential. High-throughput Ion sequencing alone revealed the presence of sub-dominant genera, including, among others, *Staphylococcus saprophyticus* and *Streptococcus thermophilus*. Actual levels of histamine and tyramine in the respective cheeses were quantified by HPLC.

**BACTERIOLOGICAL QUALITY OF COMMERCIALLY PREPARED FERMENTED OGI (AKAMU) SOLD IN SOME PARTS OF SOUTH EASTERN NIGERIA**

A.C. Ogodo<sup>1</sup>, O.C. Ugbogu<sup>1</sup>, U.G. Ekeleme<sup>2</sup>

<sup>1</sup>*Microbiology, Federal University Wukari, Wukari, Nigeria*

<sup>2</sup>*Biology and Microbiology, Gregory University Uturu, Uturu, Nigeria*

**Background**

Food poisoning and infection by bacteria are of public health significance to both developing and developed countries.

**Objectives**

This study compared the bacteriological qualities of commercially and laboratory based fermented ogi (akamu) prepared from maize.

**Methods**

Samples of ogi (akamu) prepared from white and yellow variety of maize sold in Uturu and Okigwe were analyzed together with the laboratory prepared ogi for microbial quality using the standard microbiological methods. The analyses showed that both white and yellow variety had total bacterial counts (cfu/g) of  $4.0 \times 10^7$  and  $3.9 \times 10^7$  for the laboratory prepared ogi while the commercial ogi had  $5.2 \times 10^7$  and  $4.9 \times 10^7$ ,  $4.9 \times 10^7$  and  $4.5 \times 10^7$ ,  $5.4 \times 10^7$  and  $5.0 \times 10^7$  for Eke-Okigwe, Up-gate and Nkwo-Achara market respectively. The Staphylococcal counts ranged from  $2.0 \times 10^2$  to  $5.0 \times 10^2$  and  $1.0 \times 10^2$  to  $4.0 \times 10^2$  for the white and yellow variety from the different markets while Staphylococcal growth was not recorded on the laboratory prepared ogi. The laboratory prepared ogi had no Coliform growth while the commercially prepared ogi had counts of  $0.5 \times 10^3$  to  $1.6 \times 10^3$  for white variety and  $0.3 \times 10^3$  to  $1.1 \times 10^3$  for yellow variety respectively. Lactic acid bacterial count of  $3.5 \times 10^6$  and  $3.0 \times 10^6$  was recorded for the laboratory ogi while the commercially prepared ogi ranged from  $3.2 \times 10^6$  to  $4.2 \times 10^6$  (white variety) and  $3.0 \times 10^6$  to  $3.9 \times 10^6$  (yellow).

**Conclusions**

There are chances of contracting food borne diseases from commercially prepared ogi. Therefore, there is the need for sanitary measures in the production of fermented cereals so as to minimize the rate of food borne pathogens during processing and storage.

## **ISOLATION AND MYCOTOXIGENIC ACTIVITIES OF SOME MYCOFLORA OF WEST AFRICAN CHEESE**

A. Ogunleye<sup>1</sup>, O. Jacobs<sup>1</sup>

<sup>1</sup>*Department of Microbiology, Lead City University, Ibadan, Nigeria*

### **Background**

Cheese(wara) is a local dairy product produced and consumed in many African countries. It is produced locally by the Fulanis who use *Calotropis procera* leaves as coagulating agent for the milk.

### **Objectives**

The isolation and identification of the fungi species present in wara and their ability to produce mycotoxins was carried out to determine the safety level associated with consumption of the cheese.

### **Methods**

Mycotoxin production was determined with the use of the enzyme-linked immunosorbent serological assay (ELISA) technique

### **Conclusions**

Some of the isolated mycoflora were found to be mycotoxigenic producing aflatoxins at various levels.

**FEMS-1195**

**INVITRO PROTEIN DIGESTIBILITY OF FERMENTED BAMBARA NUT  
(VOANDZEA SUBTERRANEAN L. THOUARS) USING DIFFERENT SPECIES OF  
RHIZOPUS**

B. Olanipekun<sup>1</sup>, E.T. Otunola<sup>1</sup>, O.J. Oyelade<sup>1</sup>

<sup>1</sup>Food Science and Engineering, lautech, ogbomoso, Nigeria

**Background**

Bambara nut as legume contains sufficient quantities of carbohydrate and protein high in lysine and methionine. Processing methods, such as soaking, cooking or fermentation can improve the quality of legume protein.

**Objectives**

Therefore, this research considered the effect of fermentation on *in vitro* protein digestibility of bambara nut

**Methods**

The bambara nut was obtained from a local market in Ogbomoso, Nigeria. Different species of *Rhizopus* for the fermentation were obtained from Ladoké Akintola University of Technology, Ogbomoso, and the Institute of Agricultural Research and Training, Ibadan to produce fermented bambara nut flour. The *In vitro* protein digestibility of the flour sample was consequently evaluated.

**Conclusions**

Fermentation process using *Rhizopus* species alone, and with their combinations showed improvement in the nutritive value of the fermented bambara nut in relation to *in-vitro* protein digestibility, and the highest rate of protein digestibility was obtained using *R. oligosporus* alone

## **SEPARATION OF LACTOBACILLI BY MEANS OF MOLECULAR TOOLS**

O. Szén<sup>1</sup>, K. Pál<sup>1</sup>, K. Váczy<sup>1</sup>, A. Juhász<sup>1</sup>

<sup>1</sup>*Egerfood Regional Knowledge Centre, Eszterházy Károly College, Eger, Hungary*

### **Background**

Various Lactobacillus species are responsible for the production of fermented food products. Prior to the use of a certain isolate for industrial purpose, it is advisable to classify it at least on species level. Nevertheless, closely related species are not easy to distinguish but molecular methods might be able to reveal the differences even on subspecies level.

### **Objectives**

The aim of our experiments was to verify the usability of several molecular methods in discrimination of Lactobacillus species and compare the efficiency of these tools.

### **Methods**

DNA of lactobacilli were subjected to investigations by PCR (general bacterial and species-specific primers) and qPCR (including newly developed primers and High Resolution Melting - HRM), RFLP and sequencing in order to compare the efficiency of these methods in separation of species.

### **Conclusions**

The HRM had proved its power as a one-step tool for preliminary classification of lactobacilli. With this method it might be much easier to separate closely related species, though, additional techniques, e.g. traditional PCR (species-specific primers), sequencing and RFLP pattern analysis might be necessary to use in order to confirm the results.

**GENOMICS OF STREPTOCOCCUS MACEDONICUS: MOVING FROM PATHOGENICITY TO ADAPTATION TO THE DAIRY ENVIRONMENT**

K. Papadimitriou<sup>1</sup>, M. Kazou<sup>1</sup>, V. Alexandraki<sup>1</sup>, B. Pot<sup>2</sup>, P. Renault<sup>3</sup>, E. Tsakalidou<sup>1</sup>

<sup>1</sup>Food Science and Human Nutrition, Agricultural University of Athens, Athens, Greece

<sup>2</sup>Center for Infection and Immunity of Lille, Institut Pasteur de Lille, Lille, France

<sup>3</sup>UMR1319 Micalis, INRA, Jouy-en-Josas, France

**Background**

Lactic acid bacteria (LAB) constitute a significant group of microorganisms for food fermentations and for human health. The *Streptococcus bovis*/*Streptococcus equinus* complex (SBSEC) within LAB includes members that have been implicated in human disease, but are also found in foods.

**Objectives**

In this study we compared the three available genome sequences of *S. macedonicus* strains isolated from dairy products. Only one strain has its genome complete sequenced and previous analysis showed diminished pathogenic potential and adaptation to the milk environment. Here we present the *in silico* analysis of these strains, in order to better understand the *S. macedonicus* species.

**Methods**

Chromosomal maps were constructed using DNAPlotter and whole genome sequence alignments were performed by progressiveMAUVE and Webact in order to visualize conserved genomic regions or chromosomal rearrangements. Genomic islands were identified and visualized by IslandViewer, potential bacteriocins were predicted by BAGEL3 and CRISPRs were analyzed by the tools available in the CRISPRcompar web-service.

**Conclusions**

The analysis revealed that *S. macedonicus* strains have lost genes involved in the catabolism of complex plant carbohydrates, in the adhesion to the host's cells and in haemolysis that are present in pathogenic SBSEC. In addition, *S. macedonicus* carries two lactose operons and a proteolytic system characteristic of dairy LAB. Our whole genome analysis of *S. macedonicus* shows adaptation traits to the nutrient-rich milk environment.

## **INACTIVATION OF BROCHOTHRIX THERMOSPACTA BY ATMOSPHERIC COLD PLASMA.**

A. Patange<sup>1</sup>, D. Boehm<sup>1</sup>, P.J. Cullen<sup>1</sup>, P. Bourke<sup>1</sup>

<sup>1</sup>*School of Food Science and Environmental Health, Dublin Institute of Technology, Dublin, Ireland*

### **Background**

*Brochothrix thermosphacta* is considered one of the predominant food spoilage organisms in meat. Atmospheric cold plasma technology (ACP) is proposed as a potential technology for elimination of microbial contamination in food products.

### **Objectives**

The aim of the study was to investigate the antimicrobial efficacy of dielectric barrier discharge atmospheric cold plasma (DBD ACP) for inactivation of *B. thermosphacta*.

### **Methods**

A large gap DBD ACP system was used to investigate the inactivation of *B. thermosphacta* ( $10^{7-8}$ CFU/ml) in PBS, liquid meat model medium (beef extract broth) and raw lamb chops. Samples were placed inside sealed rigid polypropylene containers and were treated with cold plasma using modified atmosphere as the inducer gas. The effect of ACP critical control parameters, such as treatment time, voltage level, media composition and post treatment temperature storage conditions against both planktonic bacteria and biofilms were evaluated. The surviving bacterial populations were estimated by colony count assay.

### **Conclusions**

ACP showed substantial reductions of bacteria depending on the growth media. ACP treatment (80kV) for 30s completely inactivated the bacterial population in PBS, while 5 min treatment showed 2 Log unit bacterial reduction with the meat model medium. The antimicrobial efficacy of plasma against bacteria on lamb chops showed a reduction around 0.5 log units over a 10 day storage period. The results indicate ACP could be effective for inactivation of *B. thermosphacta* if treated with sufficient treatment periods providing a prolonged shelf life for meats and meat products. Further studies will investigate the effect of extended ACP treatment times for complete inactivation.

<sup>2</sup>The Key Laboratory of Molecular Microbiology and Technology Ministry of Education, Nankai University, Tianjin, China

### **Background**

Minimum genome factories (MGFs) can be defined as recombinant strains whose metabolic pathways have been optimized for special applications. The plasticity of genomes gives us hints that it is probable to streamline physiological pathways through genome rearrangements as strains possess a number of non-essential genes. Lactic acid bacteria (LAB) are low G-C content Gram-positive bacteria and have relatively small genome. *Lactococcus lactis* could be served as the starting platform for value-added metabolites biosynthesis. Construction of a set of chassis cells provides the opportunity to obtain specific strains with desired performance.

### **Objectives**

To delete the large-scale genes in *Lactococcus lactis* and construct the set of chassis cells for further synthetic biology research.

### **Methods**

The Cre-*loxP* recombination system was used to construct a large scale region (19.0 kb) deficient strain N8 $\Delta$ L1. Two *loxP* sites were integrated into the genome at target sites, and the large scale region (L1) was replaced by a *cat*-cassette. The recombination between two *loxP* sites was achieved when the Cre recombinase was expressed by constructed pNZTS-Cre plasmid, and then the L1-null strains were isolated. Despite the loss of 19.0-kb regions, the strain N8 $\Delta$ L1 still exhibited normal growth and similar growth profile was also observed compared to the parental strain.

### **Conclusions**

The Cre-*loxP* recombination system can be used for large-scale genome deletion and generate sequential chromosomal modification mutants of *L. lactis* efficiently. Based on the precision of its deletion, further genome streamlining and advance the regulatory network study about synthetic biology could be easily achieved.

<sup>3</sup>Università degli Studi del Molise, Dip AAA, Campobasso, Italy

### **Background**

*Lactobacillus casei* is a lactic acid bacterium (LAB) used in the production of many fermented food and feed products. Furthermore, this specie comprises strains commercially exploited as probiotic cultures. Thus, novel strategies to improve their adaptation to adverse conditions could enhance their safety, functional and technological properties. Recently, it has been demonstrated that respiratory metabolism results in this species in the expression of a phenotype with enhanced technological and stress response properties (increase in biomass, synthesis of antioxidant enzymes, robustness to stress conditions).

### **Objectives**

The aim of the study was evaluating the impact of respirative/anaerobic metabolism of *L. casei* N87 strain on model sourdough fermentation.

### **Methods**

The strain *L. casei* N87, grown both in anaerobic and respirative conditions, was inoculated as starter in wheat flour in combination with a commercial baker's yeast culture. After 0, 6 and 24 h of fermentation LAB count, pH and Titratable acidity values, free amino acid (FAA), volatile compounds (VOCs) (by SPME-GC-MS), antioxidant activity (by DPPH assay) and albumins/globulins, gliadins and glutenins protein fractions (by SDS-PAGE) were evaluated.

### **Conclusions**

A major increase in biomass for the strain *L. casei* N87 grown in respirative condition was registered after 6h of fermentation. Results obtained by FAA and VOCs evaluation indicated that respirative metabolism of *L. casei* N87 influences the flavour of sourdough. Furthermore, SDS-PAGE highlighted a different wheat protein degradation in anaerobic/respirative cultures. In conclusion, respirative *L. casei* N87 performs well in sourdough definition and a better explanation of its role in sourdough production is considered opportune.

**MICROBIAL CHARACTERIZATION, TOTAL POLYPHENOLS CONTENT AND ANTIOXIDANT ACTIVITY OF CHENOPODIUMQUINOA AND AMARANTHUS SEEDS FROM CAMPANIA REGION**

*T. DI RENZO<sup>1</sup>, A.N.N.A. Reale<sup>1</sup>, M. PREZIUSO<sup>1</sup>, T. ZOTTA<sup>1</sup>, M. Volpe<sup>1</sup>, A. LAVIN<sup>2</sup>, R. COPPOLA<sup>3</sup>*

<sup>1</sup>ISA-CNR, Istituto di Scienze dell'Alimentazione - CNR, Avellino, Italy

<sup>2</sup>Isafom-CNR, Istituto per i Sistemi Agricoli e Forestali del Mediterraneo C.N.R., Ercolano (Na), Italy

<sup>3</sup>Università degli Studi del Molise, Dip AAA, Campobasso, Italy

**Background**

*Chenopodium quinoa* and *Amaranthus* spp. are considered pseudocereals characterized by high nutritional and functional values which are associated with the quality and quantity of their proteins, fats and antioxidant compounds. In the recent years, these pseudocereals have attracted the interest of research for their exploitation in the production of gluten-free products and food products with improved nutritional and health benefits.

**Objectives**

To characterize quinoa and amaranth seeds (produced in Campania Region) for microbiological, technological and safety aspects with the aim to use them in the production of “functional foods”

**Methods**

Three samples of *Amaranthus* (accessions A1, A2 and A3) and three samples of *Chenopodium quinoa* seeds (2 Titicaca and 1 Puno varieties) were obtained by experimental fields of Vitulazio (Campania Region). Total mesophilic count, lactic acid bacteria (LAB), yeasts, moulds, *Enterobacteriaceae*, enterococci, total and faecal coliforms were assessed by standard pour-plate technique by using selective media. Total polyphenols content was determined using a method based on Folin-Ciocalteu reagent, while antioxidant activity was carried out spectrophotometrically using DPPH (2,2-diphenyl-1-picrylhydrazyl) radical scavenging.

**Conclusions**

Results evidenced a high LAB concentration in quinoa and amaranth seeds ranged between 2.5 and 7.5 log CFU/g and between 2.8 and 5.0 log CFU/g, respectively. Quinoa seeds showed higher level of polyphenol content compared with amaranth, whereas no significant differences were observed in antioxidant activity, registered in high concentration for both the seeds. In conclusion, the characteristics of these seeds are highly desirable for the production of both gluten-free products and food with high nutritional value.

**UNDERSTANDING DIVERSITY OF BACTERIAL COMMUNITIES FROM POULTRY MEAT TO IMPROVE FOOD QUALITY AND SAFETY**

A. Rouger<sup>1</sup>, B. Remenant<sup>1</sup>, H. Prévost<sup>1</sup>, M. Zagorec<sup>1</sup>

<sup>1</sup>UMR 1014 SECALIM, Oniris INRA, Nantes, France

**Background**

Meat products can host variable microbial communities according to seasonal changes and production processes. These may encompass pathogenic or spoilage bacteria which must be controlled to ensure safety and quality of the products.

**Objectives**

Our aim was to describe the microbial community of chicken legs packaged under modified atmosphere.

**Methods**

Whole bacterial populations were collected and stored frozen at -80°C. Their ability to regrow on meat was checked. Bacterial diversity was determined by cultural methods (23 samples) and by 16S rDNA pyrosequencing (10 samples).

**Conclusions**

Total viable counts varied with samples ( $10^3$  -  $10^8$  CFU/g) and plating methods showed that lactic acid bacteria, *Brochothrix thermosphacta*, and *Pseudomonas* spp. were the main bacterial. The characterization of the bacterial diversity by 16S rDNA pyrosequencing confirmed the presence of *B. thermosphacta*, and revealed that *Pseudomonas* was mainly represented by *P. extremaustralis* and *P. cedrina*. As well the main LAB species were *Carnobacterium* and *Shewanella* species. The predominance of *Pseudomonas* was correlated to meat packaging under high oxygen concentration, except when *B. thermosphacta* was dominant, suggesting a competition between these species. No clear cut correlation could be observed between farming practices or meat processing and bacterial communities. However, our results showed similar microbial profiles of samples issued from the same slaughterhouse suggesting the main contamination may occur during this processing. The frozen communities will now be used to evaluate the abiotic and biotic (e.g. the *Brochothrix-Pseudomonas* competition) factors in reproducible challenge tests on meat to finally improve the storage life-time

Escola Superior de Biotecnologia Universidade Católica Portuguesa/Porto, Porto,  
Portugal

### **Background**

Fungal growth is the main cause of fruit decay, and is usually control by the application of synthetic fungicides, however, currently their used have been restricted. Therefore, it is urgent to find alternative antifungal substances. Phenolic compounds are secondary metabolites of plants and naturally present in fruit which have been associated with antimicrobial effect. Citrus peel contains high amount of flavonoids and is the main byproduct of processing industry

### **Objectives**

Then, the aim was to investigate the inhibitory activity of phenolic extracts obtained from citrus peel against fungal fruit spoilage.

### **Methods**

The antifungal activity of extracts from orange and lemon peels were tested *in-vitro* against 6 yeast strains (*Cryptococcus* spp., *Torulaspora* spp, *Aerobasidium pullulans*, *Rhodoturula* spp., *Hanseniaspora uvarum*., *Meyerozyma caribbica*) and 8 molds (*Botrytis cinerea*, *Monilia laxa*, *Alternaria* spp., *Penicillium glabrum*, *Penicillium expansum*, *Penicillium corylophilum*, *Cladosporium uredinicola*, *Cladosporium cladosporioides*), by following the ability to grow in a medium containing different concentrations of extracts.

### **Conclusions**

Overall, the inhibitory effect of orange extracts (OE) against yeast strains was around 90% at concentrations higher than 0.75 g/L, whereas the effect of lemon extracts was more strain dependent and powerful, with values closed to 90% against four strains at 0.15 g/L. On the other hand, although inhibitory effect against molds was lower, OE presented a remarkable activity against *B. cinerea*, *M. laxa* and *Alternaria* spp. and moderated against *Penicillium* and *Cladosporium* strains. In conclusion, these results suggest the possibility of using citrus polyphenolic extracts as a safer alternative to synthetic fungicides to control postharvest decay of fruit.

**LISTERIA MONOCYTOGENES OF SEQUENCE TYPE 121 HARBOR SPECIFIC ADAPTATIONS SUPPORTING PERSISTENCE IN FOOD PRODUCTION PLANTS.**

K. RYCHLI<sup>1</sup>, A. Müller<sup>1</sup>, A. Zaiser<sup>1</sup>, M. Wagner<sup>1</sup>, S. Schmitz-Esser<sup>1</sup>

<sup>1</sup>Department for Farm Animals and Veterinary Public Health,  
Institute for Milk Hygiene, Vienna, Austria

**Background**

The foodborne pathogen *Listeria monocytogenes* is able to survive for months and even years in food production environments. Among a great strain diversity particularly strains belonging to sequence type (ST)121 are persistent in food production plants.

**Objectives**

To elucidate the molecular determinants responsible for persistence of *L. monocytogenes*.

**Methods**

We analysed the genomes of two *L. monocytogenes* ST121 strains, which persisted for up to eight years in food production plants in Ireland and Austria. Additionally we characterized two ST121 strain-specific genetic features: Tn6188 and *lin0464/lin0465*.

**Conclusions**

All ST121 genomes are highly similar and show a tremendously high degree of conservation among prophages and particularly among their plasmids, which are usually variable parts of genetic information in bacteria. This remarkably high level of conservation suggests a strong selective pressure.

In addition, all ST121 strains share adaptations related to persistence in food production environments such as the presence of Tn6188, a transposon responsible for increased tolerance against quaternary ammonium compounds, and the presence of homologues of the *L. innocua* genes *lin0464* and *lin0465*, a transcriptional regulator and a putative pfpl protease. Deletion of *lin0465* resulted in reduced survival under oxidative and alkaline conditions suggesting a role in stress response. Furthermore all ST121 strains reveal a yet undescribed insertion harboring recombination hotspot (RHS) repeat proteins, which are most likely involved in

competition against other bacteria. In conclusion we show that *L. monocytogenes* ST121 strains are highly similar to each other harboring conserved regions which provide fitness adaptations to survival in food production environments.

**NOVEL VIRULENCE FEATURES OF LISTERIA MONOCYTOGENES ISOLATED FROM FOOD SAMPLES SOLD AT A ROMANIAN BLACK MARKET.**

*L. Ciolacu<sup>1</sup>, A.I. Nicolau<sup>2</sup>, M. Wagner<sup>1</sup>, K. RYCHLI<sup>1</sup>*

<sup>1</sup>*University of Veterinary Medicine Vienna, Institute for Milk Hygiene, Vienna, Austria*

<sup>2</sup>*"Dunarea de Jos" University of Galati, Faculty of Food Science and Engineering, Galati, Romania*

**Background**

*Listeria monocytogenes* is a facultative intracellular foodborne pathogen responsible for listeriosis. Investigated neglected exogenous routes of transmission of foodborne pathogens into the EU, we have isolated 15 *L. monocytogenes* strains in food products illegally sold at a Romanian black market.

**Objectives**

The aim of this study was to characterize the subtype and the virulence features of these *L. monocytogenes* strains.

**Methods**

We determined invasion efficiency and intracellular growth in human intestinal epithelial Caco2 and macrophage-like THP1 cells; and analysed the sequence of three main virulence factors: PrfA, internalin A (InlA) and listeriolysin O (LLO).

**Conclusions**

Multilocus sequence typing revealed that these *L. monocytogenes* strains belong to six different sequence types (ST). *In vitro* virulence assays showed a high strain variability regarding the invasion efficiency in Caco2 cells and the intracellular growth rate in both cell types. In parallel we revealed a high diversity in the InlA and LLO amino acid sequences, however strains belonging to the same ST harbour identical sequences. We detected in total 30 different amino acid substitutions, resulting in seven different InlA variants, two of which have not yet been described. All ST121 and ST9 strains, harbouring a premature stop codon resulting in truncated InlA, were unable to invade Caco2 cells. In addition the number of LLO mutations correlated negatively with intracellular growth in both cell types; and all ST155 strains showed no proliferation inside macrophages. In conclusion, we show a high diversity in the amino acid sequence of main virulence factors in *L. monocytogenes* resulting in distinct virulence profiles.

**FEMS-2013**

**Food microbiology**

**CELL-CONTACT DEPENDENT COMPETITION OF *L. MONOCYTOGENES* STRAINS EFFECTS FITNESS AND VIRULENCE.**

*E. Zilelidou*<sup>1</sup>, *E. Manthou*<sup>1</sup>, *L. Ciolacu*<sup>2</sup>, *M. Wagner*<sup>2</sup>, *P. Skandamis*<sup>1</sup>, *K. RYCHL*<sup>2</sup>

<sup>1</sup>*Agricultural University of Athens, Food Technology Lab, Athens, Greece*

<sup>2</sup>*University of Veterinary Medicine Vienna, Institute for Milk Hygiene, Vienna, Austria*

**Background**

Interactions of bacteria living in the same microenvironment influence the behaviour of pathogens like *Listeria monocytogenes*. Therefore inter-strain competition between different *L. monocytogenes* strains could influence fitness and pathogenicity.

**Objectives**

This study investigated the impact of co-culture on growth and *in vitro* virulence of *L. monocytogenes* strains and the effect of cell-contact on the observed growth and virulence competition.

**Methods**

Growth of eight *L. monocytogenes* strains was determined in single and two-strain mixed cultures in tryptic soy broth at 10°C for 10 days. The effect of strain competition (24h, 10°C) on invasion efficiency and intracellular growth was investigated using human intestinal epithelial Caco2 cells. Two selected strains were inoculated singly, mixed or separated by 0.4µm PET-membrane to analyzed whether the observed effects are cell-contact dependent.

**Conclusions**

Significant differences in growth between single and mixed cultures were observed for certain strains e.g. ScottA and 6179 showed reduced growth rates when co-cultivated with other strains. Cell-contact was essential for growth competition.

High virulent strain e.g. PL25 showed either increased or unchanged invasion efficiency when co-cultured with low virulent strains, whereas the invasiveness of low virulent strains like ScottA and 6179 was attenuated. These results suggest a competitive advantage for the strains displaying higher invasion efficiency. In parallel to growth the effect of strain competition on virulence is cell-contact dependent.

In conclusion competition between *L. monocytogenes* strains has a strain-dependent effect on fitness and virulence.

## **NEW INSIGHTS OF A NATURAL GUM: FOCUSING ON GUT ECOLOGY.**

A. Samanta<sup>1</sup>, D. Mitra<sup>1</sup>, A. Jena<sup>1</sup>, A. De<sup>1</sup>

<sup>1</sup>Department of Pharmaceutical Technology, Jadavpur University, KOLKATA, India

### **Background**

Gum odina obtained from bark of *Odina wodier* (Anacardiaceae) is evaluated as prebiotic in this study. The natural gum (polysaccharide) is chemically galactopyranose associated with arabinose side chain.<sup>[1]</sup>

### **Objectives**

The use of prebiotic to fortify gut flora is current aspect of research for the control and prevention of colon cancer as well as boosting of immune system.

### **Methods**

*In vivo* prebiotic potential of gum odina was performed on Swiss albino mice by deliberate challenging of *S.typhi* 62 focusing on immunological parameters<sup>[2]</sup> and *in vitro* studies was investigated by Simulator for Human Intestinal Microbial Ecosystem (SHIME).<sup>[3]</sup>

### **Conclusions**

The non-degradability of gum odina by simulated gastric fluid (SGF) and simulated intestinal Fluid (SIF) attributes to one of the major characteristics of prebiotics i.e. indigestible carbohydrate. Microbial analysis of SHIME studies shows increase in colonization of various probiotic organisms such as *Lactobacillus* sp. and *Bifidobacterium* sp. upon administration of odina. *In vivo* study revealed natural gum selectively stimulates probiotic strains and eliminates enteric pathogens and also boosts immune system by increasing sIgA in gut. Moreover increase in levels of IFN  $\gamma$  signifies additional protection against various pathogen induced primary and secondary infections. This gum is also believed to possess colon carcinoma preventing properties as it liberates short chain fatty acids (SCFA) upon fermentation which we are planning to focus in our next studies.

## USE OF BACTERIAPHAGE-BASED SOLUTION AND ELECTROLYZED OXIDIZING WATER AS ALTERNATIVE SANITIZING SOLUTIONS TO INACTIVATE LISTERIA MONOCYTOGENES ON FOOD CONTACT SURFACES FOR THE SEAFOOD PROCESSING FACILITIES

E. Sen Yilmaz<sup>1</sup>, S. Benjakul<sup>2</sup>, S. Çaklı<sup>1</sup>, K. Vongkamjan<sup>2</sup>

<sup>1</sup>Fisheries Faculty Section of Seafood Processing, Ege University, Izmir, Turkey

<sup>2</sup>Food Technology, Prince of Songkla University, Hat-Yai, Thailand

### Background

*Listeria monocytogenes* is an important foodborne pathogen that can cause serious public health-related issues worldwide. *L. monocytogenes* could be isolated from food contact surfaces (FCS) from the seafood processing facilities, e.g., slicers, utensils, knives, sieves, conveyors, towels, employer's gloves, which could then link to the occurrence of cross-contamination of seafood products.

### Objectives

Effective sanitizing agents are thus needed to reduce the incidence of *Listeria* contamination on FCS. In this study.

### Methods

Phage-based solution LP-124 (LPS; broad host-range listeriaphage) and electrolyzed oxidizing water (EOW; pH 2.5 and ORP 1150 mV) were evaluated for the ability to inactivate *L. monocytogenes* cells that were artificially contaminated on four different FCSs (plastic cutting board, towel, stainless steel spoon, and sieve) at 4 logCFU/cm<sup>2</sup> on a given FCS.

### Conclusions

Results showed that EOW and LPS led to significantly ( $p < 0.05$ ) decrease of *L. monocytogenes* counts, representing about 2 logCFU/cm<sup>2</sup> on a given FCS, [KV1] compared with the counts recovered from washing with water. *L. monocytogenes* counts were not detected in the previously used EOW solution stored at 4 °C during 7 days after used, while about 2.8 logCFU/ml was observed in used phage-based solution after 7 days of storage. Both EOW and LPS can effectively inactivate *L. monocytogenes* on different food contact surfaces, and can further be used as alternative sanitizing solution for the seafood processing facilities.

**PREVALENCE OF INTESTINAL PARASITES AMONG FOOD HANDLERS OF SARI, NORTHERN IRAN**

M. Sharif<sup>1</sup>, A. Daryani<sup>1</sup>, E. Kia<sup>1</sup>, F. Rezaei<sup>1</sup>, M. Nasiri<sup>1</sup>, M. Nasrolahei<sup>1</sup>

<sup>1</sup>Parasitology, Mazandaran University of Medical Sci, Sari, Iran

**Background**

Parasitic infection is highly prevalent throughout the developing countries of the world. Food handlers are potential source of infection of many intestinal parasites and other enteropathogenic infections as well

**Objectives**

The aim of this study was to determine the prevalence of intestinal parasites carriers among food handlers attending the public healthcenter laboratory in Sari, northern Iran for annual check-up

**Methods**

The study was performed from August 2011 through February 2012. Stool samples were collected from 1041 male and female food handlers of different Jobs aged between 18 to 63 years and were examined following standard procedures. Sociodemographic, environmental and behavioral data of the food handlers were recorded in a separate questionnaire. Intestinal parasites were found in 161(15.5%) of the studied samples. Seven species of protozoan orhelminth infections were detected. Most of the participants were infected with Giardia lamblia (53.9%) followed by Blastocystis hominis (18%), Entamoeba coli (15.5%), Entamoeba histolytica/dispar (5.5%), Cryptosporidium sp. (3.1%), Iodamoeba butschlii (3.1%) and Hymenolepis nana (1.9%) as an only helminth infection.

**Conclusions**

The finding emphasized that food handlers with different pathogenic organisms may predispose significant risk on the consumers. Routine screening and treatment of food handlers is a proper tool in preventing the food-borne infections.

**Food microbiology**

## **IDENTIFICATION AND EVALUATION OF ANTIBIOTIC RESISTANCE OF PROBIOTIC STRAINS OF BIFIDOBACTERIA IN BELARUS**

A. Sidarenka<sup>1</sup>, T. Karpenka<sup>2</sup>, M. Pasciak<sup>3</sup>, A. Gamian<sup>3</sup>, G. Novik<sup>1</sup>

<sup>1</sup>Microbial Collection, Institute of Microbiology Belarus National Academy of Sciences, Minsk, Belarus

<sup>2</sup>Immunochemical and Molecular Biology Diagnostic Tools, Institute of Bioorganic Chemistry Belarus National Academy of Sciences, Minsk, Belarus

<sup>3</sup>Medical Microbiology, Ludwik Hirszfeld Institute of Immunology and Experimental Therapy Polish Academy of Sciences, Wroclaw, Poland

### **Background**

Accurate identification and assessment of antibiotic resistance of bifidobacteria are essential to secure quality and safety of probiotics and food products, containing these microorganisms.

### **Objectives**

The objective of the work was identification and evaluation of antibiotic resistance of 25 probiotic strains of bifidobacteria, isolated from feces of healthy adults, therapeutical preparations and dairy products, marketed in Belarus.

### **Methods**

Sequencing of 16S rDNA and transaldolase gene, MALDI-TOF MS protein profiling, biochemical testing, analysis of fatty acid methyl esters (FAMES) were used for bifidobacteria identification. PCR-analysis, disc-diffusion and broth micro-dilution methods were applied for determination of antibiotic resistance of bifidobacteria.

### **Conclusions**

Results of molecular-genetic identification of bifidobacteria indicated that 7 strains belong to species *Bifidobacterium animalis* subsp. *lactis*, 7 strains – *Bifidobacterium longum*, 5 strains – *Bifidobacterium bifidum*, 5 strains – *Bifidobacterium adolescentis*, 1 strain – *Bifidobacterium breve*. MALDI-TOF MS analysis confirmed taxonomic affiliation of tested strains and proved to be a rapid and reproducible technique for bifidobacteria identification. Protein biomarkers suitable for species and strain discrimination were defined. Both biochemical testing, based on evaluation of enzymatic activity and carbohydrates fermentation, and FAMES analysis did not provide accurate species identification of bifidobacteria, but were useful for strain differentiation and characterization. Tested strains of bifidobacteria were susceptible to chloramphenicol (100%), penicillin G (96%), amoxicillin (96%), ampicillin (88%), streptomycin (80%), vancomycin (80%), gentamycin (76%), resistant to erythromycin (40%), clindamycin (40%), tetracycline (52%), and harbor genes *tet(W)* (36%), *tet(M)* (16%), *erm(X)* (32%), *erm(B)* (8%). Gene *tet(W)* was detected in all *B. animalis* subsp. *lactis* strains, gene *erm(X)* – all *B. longum* strains.

**FEMS-2227**

**Food microbiology**

**INFLUENCE OF TEMPERATURE AND INOCULUM SIZE ON SPORES GERMINATION PERCENT OF CLOSTRIDIUM ALGIDICARNIS AND CLOSTRIDIUM ESTERTHETICUM**

A. Silva<sup>1</sup>, P. Massaguer<sup>1</sup>

<sup>1</sup>Fundação Tropical de Pesquisa André Tosello,  
LABTERMO - Thermobacteriology Laboratory, Campinas, Brazil

**Background**

'Blown pack' spoilage causes high economic losses for Brazilian meat industry.

**Objectives**

This research aimed to determine the influence of temperature and inoculum size on spore germination percent of *C.algidicarnis*, isolated from spoiled vacuum meat and *C.estertheticum* DSM8809, both recognized for their package blowing ability.

**Methods**

A central composite design - 2 factors x five levels - was applied: storage temperature (-2,3,7,11, 15°C) and inoculum size (10<sup>1</sup>, 10<sup>2</sup>, 10<sup>3</sup>, 10<sup>4</sup> and 10<sup>5</sup> spores/mL, previously prepared). Experiments were conducted using RCM media, in anaerobic conditions. Counts were performed daily, during 30 days, using NMP method. Spores germination percent (SGP) for each day was calculated as: SGP (%) = (count of germinated cells/initial spore inoculum) \* 100).

**Conclusions**

In all assays, for both microorganisms, germination was observed. *C.estertheticum* germinated faster than *C.algidicarnis* at lower temperatures: at 3°C/10<sup>2</sup> spores of inoculum, after 1 day all spores, initially inoculated, were germinated and for *C.algidicarnis*, 100% germination was reached after 4 days. In addition, at 11°C/10<sup>2</sup> sp/mL, germination of *C.estertheticum* was slower than *C.algidicarnis*, achieving 100% after 11 days. For inoculum of 10<sup>3</sup> spores/mL, *C.algidicarnis* reached high germination percent quickly at 15°C (52.4% after 2 days) while *C.estertheticum*, at 7°C (39% at 2 days). Increasing initial inoculum size from 10<sup>2</sup> to 10<sup>4</sup> spores/mL/3°C, increased the time for total germination from 4 to 10 days for *C.algidicarnis* and from 1 to 15 days for *C.estertheticum*. These results clearly show that tested temperatures were not enough to inhibit spores germination of both microorganisms, even if initial population is 10<sup>1</sup> spores/mL, emphasizing the need to avoid the vacuum packed red meat clostridial spore contamination before packaging.

**Food microbiology**

**THE EFFECTS OF ANTIBIOTICS AND DIFFERENT HOSTILE CONDITIONS ON SURVIVAL AND ADHESION OF PROBIOTIC LACTIC ACID BACTERIA IN VITRO IN MODEL OF HUMAN GASTROINTESTINAL TRACT**

D. Soghomonyan<sup>1</sup>, K. Harutyunyan<sup>1</sup>, A. Trchounian<sup>1</sup>

<sup>1</sup>Microbiology plants and microbes biotechnology, Yerevan State University, Yerevan, Armenia

**Background**

The probiotic microorganisms must be able to survive during passing through the hostile conditions of the gastrointestinal tract and have an ability to adhere to the intestinal epithelial cells. Nowadays there are many physical and chemical factors affecting these abilities of probiotics.

**Objectives**

In this work was studied the effects of electromagnetic irradiation at the frequencies 51.8 and 53 GHz (1h) and antibiotic ceftazidime (20 µM) on survival of *Lactobacillus acidophilus* VKMB-1660 *in vitro* in model of gastrointestinal tract.

**Methods**

Bacteria developed in artificial gastric juice (treatment time 20 min) with pepsin (0.3%) and different pHs (2,0, 3,0, 4,0, 5,0) and artificial intestine juice (treatment time 1 h) with bile salts (0.45%) and pancreatin (0.1%) at pH 8.0. Moreover it was studied the effects of antibiotics and different pHs (5.5, 6.5 and 8.0) on adhesiveness of bacteria.

**Conclusions**

The results obtained shown that the colony forming unit number significantly decreased, in artificial gastric juice than in intestine juice in comparison with untreated control samples. The irradiation at both frequencies and ceftazidime significantly decreased the viability of bacterial samples in both gastric and intestine juices. Moreover, ceftazidime suppressed the adhesion ability of bacteria at all pHs used in comparison with untreated samples and adhesiveness was much weaker at pHs 5.5 and 8.0 than at pH 6.5.

Thus, lactic acid bacteria *L. acidophilus* can survive in viable state in the gastrointestinal tract even after irradiation and treatment with antibiotics, but antibiotics can significantly decrease an adhesion of lactic acid bacteria to intestine mucosa.

**FEMS-2524**

## **HYGIENE BARRIERS IN FOOD PROCESSING FACILITIES MAY SERVE AS “TROJAN HORSES” FOR *L. MONOCYTOGENES***

B. Stessl<sup>1</sup>, L. Simmer<sup>1</sup>, M. Muhterem-Uyar<sup>1</sup>, S. Muri-Klinger<sup>1</sup>, S. Schmitz-Esser<sup>1</sup>, M. Wagner<sup>1</sup>

<sup>1</sup>Vetmeduni Vienna, Institute of milk hygiene milk technology and food science, Vienna, Austria

### **Background**

**Generally, hygiene sluices are efficient barriers against the transmission of spoilage and foodborne pathogen bacteria.**

### **Objectives**

The aim of the study was to determine the efficiency of hygiene sluices on the reduction of hygiene indicator bacteria and zoonotic agents in food processing companies

### **Methods**

We included five food processing facilities located in Upper- and Lower Austria. Samples were taken before and after sanitation comprising personal fingerprints, swab samples from shoes and the hygiene lock, and water residues and investigated according to microbiological standard methods. *L. monocytogenes* were subtyped by Serogroup PCR and pulsed-field gel electrophoresis (PFGE).

### **Conclusions**

One shoe sample each was found positive for *E. coli* (*rfbE* positive) and *Salmonella* spp. after sanitation in slaughterhouse B and RTE-food producer C, respectively.

Coliform bacteria and *L. monocytogenes* on shoes could not be reduced after passing the hygiene locks. In detail, 29% of the shoe samples were detected *L. monocytogenes* positive before and after the foot bath. Most of *L. monocytogenes* isolates were found on shoes of two slaughterhouses and one RTE-food company working staff. Subtyping revealed that the slaughterhouse A harbored *L. monocytogenes* serogroup 1/2a, 3a and 4b, 4d, 4e (n=21) resulting in five PFGE pulsotypes. In slaughterhouse B *L. monocytogenes* serogroup 1/2a, 3a, 1/2c, 3c and 4b, 4d, 4e (n=11) was present, representing five PFGE pulsotypes. In one RTE-food producing company genetic lineage II (1/2a, 3a; 1/2c, 3c; n=10) were over represented, including persistent strains. Hygiene locks, if not efficiently working, could be a reservoir for human pathogen bacteria and widely distributed *L. monocytogenes* clones.

## **DIVERSITY AND ANTI-LISTERIAL POTENTIAL OF BACTERIAL FLORA ON HARD-CHEESE RINDS**

S. Muri-Klinger<sup>1</sup>, C. Wanek<sup>1</sup>, O. Bereuter<sup>1</sup>, M. Wagner<sup>1</sup>, B. Stessl<sup>1</sup>

<sup>1</sup>Vetmeduni Vienna, Institute of milk hygiene milk technology and food science, Vienna, Austria

### **Background**

Vorarlberger Mountain cheese Protected Designation of Origin (PDO) owes its special characteristics from the raw milk of extensively farmed cows grazing wild herbs on alpine pastures during the summer months.

### **Objectives**

The aim of the study was to determine the diversity of bacterial flora on hard-cheese rinds isolated from artisan Vorarlberger Mountain cheese. A further goal was to test their antilisterial capability.

### **Methods**

The bacterial rind flora of seven cheese samples, including the variety of three ripening cellars (A, B, C) and two different ripening stadiums, were characterized. Furthermore, five cheeses were investigated during a six month period, to determine the variations in bacterial groups on cheese surfaces due to failures or instabilities in cheese-curing. Bacterial cheese flora isolates were enumerated and confirmed applying standard agar isolation methods and 16S rRNA sequencing. The antilisterial potential of 56 cheese rind bacteria was tested in an agar-overlay model against *Listeria* spp. Additionally, cheese rind bacteria with antilisterial potential and a brine-adapted *L. monocytogenes* isolate were introduced in a challenge experiment on cheese during ripening.

### **Conclusions**

The majority of isolates comprised following genera and species: *Brevibacterium* spp. (30.9%), *Staphylococcus equorum* (20.9%), *Corynebacterium casei/variabilis* (11.4%) and *Brachybacterium alimentarium* (10.9%). Antilisterial potential in the agar model was observed from 30.4 % of test strains. In the challenge experiment higher *L. monocytogenes* spike levels ( $10^4$  cfu) were positive after enumeration and enrichment until the end of smearing at day 14. Applying a brine with higher salt concentration (>20%) resulted in higher growth rates during ripening (average  $3.98 \times 10^3$  cfu/g).

## **MICROBIAL QUALITY OF EDIBLE INSECTS**

J. Stoops<sup>1</sup>, J. Claes<sup>1</sup>, B. Lievens<sup>2</sup>, L. Van Campenhout<sup>1</sup>

<sup>1</sup>Department of Microbial and Molecular Systems, KU Leuven, Geel, Belgium

<sup>2</sup>Department of Microbial and Molecular Systems, KU Leuven, Sint-Katelijne-Waver, Belgium

### **Background**

Current animal protein sources will not be sufficient for the growing population. Therefore, alternative solutions need to be found. Edible insects are considered as a sustainable and nutritionally equivalent alternative to meat. Nowadays, there is a lack of profound insight into the microbiological quality of edible insects.

### **Objectives**

The purpose of this research was to investigate the microflora of edible insects in a quantitative and a qualitative way, in particular of the yellow mealworm (*Tenebrio molitor*) and the grasshopper (*Locusta migratoria migratorioides*).

### **Methods**

Living insects for human consumption were purchased from an eco-shop (Belgium). Both insect species were subjected to culture-dependent analyses (classical microbial counts) to determine the microbial load (total aerobic count (TAC), *Enterobacteriaceae*, lactic acid bacteria (LAB), yeasts and moulds (Y&M) and aerobic bacterial spores). In addition, culture-independent analyses (454 pyrosequencing) were performed to gain insight into the bacterial community composition.

### **Conclusions**

Average microbial counts (3 batches, log cfu/g) in mealworms were 8,0 TAC, 7,3 *Enterobacteriaceae*, 7,4 LAB and 5,4 Y&M. Lower counts were observed for sporeforming bacteria ranging between <1,0-3,5 log cfu/g. Grasshoppers showed average counts (2 batches, log cfu/g) of 7,2 TAC, 5,6 *Enterobacteriaceae*, 7,0 LAB, 4,2 Y&M and 4,2 bacterial spores. The culture-independent analyses demonstrated a high bacterial diversity in mealworms and grasshoppers. Most bacteria belonged to the *Enterobacteriaceae* and LAB, however, the dominant bacterial species differed between both insect species. Hence, raw edible insects contain a high microbial load and diversity, including spoilage organisms and potential pathogens, a decontamination step before consumption is required.

**A TEN-YEAR SPOT-SAMPLING (2005-2014) OF FISH, WATER AND SURFACES  
ALONG THE PRODUCTION CHAIN IN THE NORWEGIAN PELAGIC FISH  
SECTOR.**

C.S. Svanevik<sup>1</sup>, I.S. Roiha<sup>1</sup>, A. Levsen<sup>1</sup>, B.T. Lunestad<sup>1</sup>

<sup>1</sup>NIFES, National Institute of Nutrition and Seafood Research, Bergen, Norway

**Background**

Microorganisms are of great importance in post-harvest spoilage of marine resources. Both quality-reducing and potential pathogenic bacteria may reduce the first-hand value, the export potential, and the reputation of the seafood industry.

**Objectives**

To examine microbiological conditions of the commercially most important pelagic fish species harvested in Norway, with respect to quality, hygiene and food safety.

**Methods**

Microbial fish quality was evaluated by heterotrophic plate counts (HPC) and counts of H<sub>2</sub>S-producing bacteria, whereas hygienic- and safety conditions were assessed by analysing for faecal indicator organisms, e.g. presumptive *E. coli* and enterococci, and the pathogens *Listeria monocytogenes*, *Salmonella* and staphylococci. Examined contact points in the production environment at vessels and factories, included surface samples of equipment and water samples associated with fish catch, -storage, and -production. Contact points were examined for HPC, Enterobacteriaceae, presumptive *E.coli*, enterococci, *Salmonella*, and *L. monocytogenes*. For evaluation, an assessment scheme with recommended microbiological limits suitable for fresh pelagic fish products are proposed based on contemporary EU- and Norwegian guidelines.

**Conclusions**

Quality-, hygienic- and food safety conditions were according to the recommended assessment scheme in all samples from 23 samplings. However, 18 samplings had samples that were not optimal and contamination of fish, the pump nozzle, sift box, sorting chambers, storage tanks, landing tanks and conveyor belts were most often recurring. Two samplings revealed that contamination early in the production chain followed the fish throughout the process, thus an increased focus on clean equipment during capture and storage is highly suggested.

**YEAST BIOFILM DEVELOPMENT AND RHEOLOGICAL PROPERTIES  
DEVELOPMENT ON TURBULENT FLOW REGIMES.**

*J.E. LOZANO<sup>1</sup>, L.I. BRUGNONI<sup>1</sup>, M.C. TARIFA<sup>1</sup>, D.B. GENOVESE<sup>1</sup>*

*<sup>1</sup>FOOD SCIENCE, PLAPIQUI (UNS-CONICET), BAHIA BLANCA, Argentina*

**Background**

In food processing lines or in complex equipment, microorganisms are exposed to varying hydrodynamic conditions caused by the flow of liquid food, and biofilms grown under a wide distribution of hydrodynamic strengths.

**Objectives**

The aim of the present work was to investigate the in situ thickness, architecture, and rheological properties of yeast biofilms growing on stainless steel under turbulent flow.

**Methods**

The yeast species used (*Rhodototula mucilaginosa*, *Candida krusei*, *Candida kefir* and *Candida tropicalis*) were isolated from an apple juice industry. Biofilm formation in turbulent flow were performed in a Rotating Disk System (RDS) already described (Brugnoni et al., 2011). Viscoelastic properties of biofilms were determined by small deformation dynamic oscillatory measurements in a Paar Physica rheometer MCR301 (Anton Paar GmbH, Graz, Austria), using parallel plates.

**Conclusions**

Results show yeasts biofilms formed on stainless steel at Reynolds (Re) numbers ranging from 294,000 to  $1.2 \times 10^6$ . These growth phases transform adherent blastospores to well-defined cellular communities. Biofilm formation increases with Re and time. Flow conditions impacted biofilm composition, with a predominance of *C. krusei*. Under turbulent flow in biofilm thickness increased  $>100 \mu\text{m}$  and cell morphology was governed by hyphal structures and rounded cells. Biofilms resulted viscoelastic materials with a solid-like behavior. Rheological values were not significantly affected by flow conditions or growth time. At large deformations their weak structure collapsed beyond a critical strain.

**ROLE OF THE COLD SHOCK DOMAIN FAMILY PROTEINS (CSPS) IN NISIN AND BENZALKONIUM CHLORIDE STRESS TOLERANCE OF LISTERIA MONOCYTOGENES**

*J. Freitag<sup>1</sup>, R. Stephan<sup>1</sup>, T. Tasara<sup>1</sup>*

<sup>1</sup>Vetsuisse Faculty, Institute for Food Safety and Hygiene, Zurich, Switzerland

**Background**

*Listeria monocytogenes* is an important foodborne pathogen that causes rare but serious illness (listeriosis) and high mortality in those with diminished immunity. Proteins of the cold shock domain family (Csps) are global gene expression regulators that promote various stress adaptation responses in bacteria. Nisin and Benzalkonium chloride (BC) are widely used antimicrobials for food preservation and disinfection of food processing environments, respectively.

**Objectives**

To investigate the functional role of Csps in the innate resistance of *L. monocytogenes* to nisin and BC stresses.

**Methods**

*L. monocytogenes* EGDe wild type and *csp* deletion mutant strains were phenotypically compared under nisin and BC stress in growth assays. Impact of nisin and BC stress on gene expression was determined using quantitative reverse transcription PCR (RT-qPCR).

**Conclusions**

In absence of Csp functions the sensitivity of *L. monocytogenes* EGDe to nisin and BC stress exposure was increased. Both growth and survival capacities of the *L. monocytogenes* EGDe strain lacking Csps were significantly diminished compared to the wild type strain when exposed to nisin and BC stress in BHI cultures. In addition the Csp-lacking EGDe strain also showed increased susceptibility to cell envelope-targeting antibiotics. Induction of *csp* genes upon exposure to nisin but not BC was also detected using RT-qPCR. A comparative gene expression analysis revealed an altered expression in genes encoding peptidoglycan-binding proteins in absence of Csp functions. Our results suggest that Csp-dependent gene expression regulation

contributes to optimal intrinsic nisin and BC resistance mechanisms in the foodborne pathogen *L. monocytogenes*.

**GENOTYPIC AND PHENOTYPIC CHARACTERISTICS OF LISTERIA MONOCYTOGENES STRAINS ISOLATED DURING 2011-2014 FROM DIFFERENT FOOD MATRICES IN SWITZERLAND**

R. Ebner<sup>1</sup>, R. Stephan<sup>1</sup>, D. Althaus<sup>1</sup>, S. Brisse<sup>2</sup>, M. Maury<sup>2</sup>, T. Tasara<sup>1</sup>

<sup>1</sup>Vetsuisse Faculty, Institute for Food Safety and Hygiene, Zurich, Switzerland

<sup>2</sup>Microbial Evolutionary Genomics, Institut Pasteur, Paris, France

**Background**

*Listeria monocytogenes* is a food-borne pathogen of public health and food safety concern responsible for highly invasive disease (listeriosis) and high mortality in those with diminished immunity.

**Objectives**

The objective of this study was to characterize *L. monocytogenes* strains recovered from different food matrices in Switzerland between 2011 and 2014 with respect to their genotypic and phenotypic properties.

**Methods**

Genotypes were determined through DNA sequencing (MLST) and PCR (stress survival islet (SSI-1), *qacH* and *bcrABC*) methods. BC resistance (BC<sup>r</sup>) was determined based on minimum inhibitory concentrations on MH agar and biofilm formation by the crystal violet staining method.

**Conclusions**

One hundred and forty two strains isolated from various food products between 2011 and 2014 in Switzerland were examined. The strains comprised serotypes 1/2a (64%), 1/2b (7%), 1/2c (12%), 3c (2%) and 4b (15%). There were 61 MLST sequence types (ST) determined including 24 new ST that had not been previously described. Fifty percent of the strains were SSI-1 PCR positive whereas 31% were negative. Remaining strains either harbored smaller than expected PCR amplicon (15%) or the SSI-1 PCR primers failed (4%) to amplify. BC<sup>r</sup> was detected in 25 (18%) strains including 20 (80%) and 3 (12%) that possessed *qacH* and *bcrABC* BC<sup>r</sup> genetic determinants, respectively. Ninety one percent of the strains were (129/142) were classified as weak, 8% (11/142) as moderate and only 1% (2/142) as strong biofilm formers. Our results indicate a high genetic and phenotypic diversity among *L.*

*monocytogenes* strains that contaminate different types of food products in Switzerland.

## **MICROBIOLOGICAL QUALITY OF FRESHLY CAUGHT FRESHWATER FISH FROM LAKES IN LATVIA**

M. Terentjeva<sup>1</sup>, I. Eizenberga<sup>1</sup>, O. Valciņa<sup>2</sup>, A. Novoslavskij<sup>3</sup>, V. Strazdiņa<sup>2</sup>, J. Ošmjana<sup>2</sup>, A. Bērziņš<sup>2</sup>

<sup>1</sup>Faculty of Veterinary Medicine Institute of Food and Environmental Hygiene, Latvia University of Agriculture, Jelgava, Latvia

<sup>2</sup>Laboratory of Food and Environmental Investigations, Institute of Food Safety Animal Health and Environment BIOR, Rīga, Latvia

<sup>3</sup>Department of Food safety and Animal Hygiene, Lithuanian University of Health Sciences/Veterinary Academy, Kaunas, Lithuania

### **Background**

Freshwater fishes are commonly used for fish preparations in Latvia and the hygienic status of a lake from there the freshwater fishes were originated may alter microbiological quality of fresh caught fish.

### **Objectives**

The aim of the present study was to detect the microbiological quality of freshly caught freshwater fish in Latvia.

### **Methods**

Altogether, 36 fishes were collected, among them 25, four and seven were European eel (*Anguilla anguilla*), silver bream (*Blicca bjoerkna*) and European perch (*Perca fluviatilis*), respectively. Samples were collected between September and November, 2014 from fishermen from lakes in Latvia. Surface swabs of a 5x5 cm<sup>2</sup> of freshly caught fish skin were examined according to ISO methods for total bacterial count (TBC), *Enterobacteriaceae*, fecal coliforms, psychrotrophic microorganisms, *Salmonella* spp., *Listeria* spp. and *Yersinia* spp.

### **Conclusions**

Counts of TBC, *Enterobacteriaceae*, fecal coliforms and psychrotrophic microorganisms were found to be significantly lower on eels than on perch and silver bream ( $p>0.05$ ). Eels in Latvia are introduced to lakes in elder or glass eel stage in the frame of eel breeding program and this could influence the contamination rates of eel microflora as they are mostly not a native part of freshwater environment. Observed significant differences ( $p>0.05$ ) between the counts of TBC,

*Enterobacteriaceae*, fecal coliforms and psychrotrophic microorganisms may be explained with the hygienic status of lake of origin of freshwater fish. Absence of *Salmonella* spp., *Listeria* spp. and *Yersinia* spp. in tested samples indicates that they do not share pathogens of public health significance.

**Background:** The stable and safe supply of plant-derived food is endangered by unusual weather, environmental pollution, and shortages of water, fossil fuel and plant biomass. When leaf vegetables are grown in the open field, their quality and productivity tend to vary with the local climate, weather conditions and soil fertility. On the other hand, when plants are grown in the greenhouse, their quality and productivity are generally improved. Thus, the plant factory is a useful system for providing the food supply. When hydroponic nutrient solution in the plant factory is contaminated by the pathogens, the pathogens will propagate and spread, quickly. And the importance of the disinfection system for hydroponic nutrient solution is pointed out in recent years.

**Objectives:** The aim of this study was to develop the disinfection system with UVA-LED and estimate the ability of disinfection of nutrient solution.

**Methods:** We developed a circulating disinfection device including a cylindrical disinfection tank of 1L volume. *Escherichia coli* strain (ATCC25922) was used as model microorganism for this study. Inactivation ability was determined by a colony-forming assay.

**Conclusions:** The disinfection system with UVA-LED was able to sterilize the hydroponic nutrient solution in the plant factory. The equation which indicated the relation between log survival ration, fluence of UVA, and energy consumption was lead by the experiments. The disinfection system with UVA-LED was excellent in not using a chemical substance and low damage to crops and hydroponic nutrient solution.

## **THE CHANGING BACTERIAL POPULATION OF FRESH-CUT ICEBERG LETTUCE DURING STORAGE**

J. van der Vossen<sup>1</sup>, E. Lommen<sup>1</sup>, E. Tsivtsivadze<sup>1</sup>, M. Paillart<sup>2</sup>, E. Woltering<sup>2</sup>, R. Montijn<sup>3</sup>

<sup>1</sup>Microbiology and Systems Biology, TNO, Zeist, Netherlands

<sup>2</sup>Food & Biobased Research, Wageningen UR, Wageningen, Netherlands

<sup>3</sup>Microbiology & Systems Biology, TNO, Zeist, Netherlands

### **Background**

Minimally processed (fresh-cut) iceberg lettuce is prone to spoilage after being harvested and processed. As the produce is not sterile, bacterial contaminants may proliferate and add to the organoleptic changes.

### **Objectives**

The objective of this study is to describe changes in the bacterial composition of modified atmospheric (MA) packed fresh-cut produce during the storage period at refrigerated temperature.

### **Methods**

Lettuce samples were taken daily during the storage period for microbiological analysis. Plate culturing was used to analyze changes in the total viable count. Application of pyrosequencing of 16S rRNA gene amplicons was used to monitor the changes in the bacterial population. Dedicated quantitative PCR (qPCR) protocols are developed to monitor the dynamics of specific bacterial entities covering *Leuconostoc*, *Lactococcus*, and *Pseudomonas*.

### **Conclusions**

The mesophilic aerobic bacterial counts increased within 8 days from about  $10^5$  to  $10^8$  colony forming units per gram of lettuce. Pyrosequencing showed at the genus level, *Pseudomonas*, *Leuconostoc*, and *Lactococcus*, being most dominant directly after packaging while *Leuconostoc* becomes most dominant while storage time is elapsing. Application of these qPCR protocols confirmed the typical change of the bacterial population of MA packed fresh-cut iceberg lettuce towards high dominant numbers of *Leuconostoc* species at day 8 after packaging. In several experiments, *Leuconostoc* spp. was found to dominate the bacterial composition at the later time points during storage, suggesting a role for *Leuconostoc*-derived metabolites in lettuce quality attributes.

**ASSOCIATION BETWEEN VIRULENCE PROFILE, SEQUENCE TYPE AND  
SEROTYPE OF SALMONELLA ENTERICA STRAINS ISOLATED FROM  
FOODSTUFFS IN MICHOACÁN, MEXICO**

L.P. Maldonado-Ruiz<sup>1</sup>, M.S. Vázquez-Garcidueñas<sup>1</sup>, G. Vázquez-Marrufo<sup>2</sup>

<sup>1</sup>*División de Estudios de Posgrado Facultad de Ciencias Médicas y Biológicas "Dr. Ignacio Chávez", Universidad Michoacana de San Nicolás de Hidalgo, Morelia, Mexico*

<sup>2</sup>*Facultad de Medicina Veterinaria y Zootecnia,  
Centro Multidisciplinario de Estudios en Biotecnología, Tarímbaro, Mexico*

**Background**

The products of the genes *invA*, *rmbA*, *ssaQ*, *sopB*, *sopE*, and *sip4-F* are involved in the invasion and infection mechanisms of *Salmonella enterica*. Virulotyping is a new scheme of genotyping based on the detection of these virulence associated genes (Virulence profile or VP) that has been proven to be an efficient tool for identification and clustering of strains/clones of *S. enterica*.

**Objectives**

Evaluate the association between VP with Sequence Type (ST), serotype, and the geographic region of provenance of *Salmonella enterica* strains.

**Methods**

Ninety strains of *S. enterica* isolated from meat and dairy products collected in the State of Michoacán, Mexico with known ST, serotype and provenance were analyzed. PCR products of the genes *invA*, *rmbA*, *ssaQ*, *sopB*, *sopE* and *sip4-F* were included in the study.

**Conclusions**

Eleven different VPs were observed and named alphabetically as A through K. VP-A contained all of the virulence genes analyzed and is widely distributed throughout the state, followed by VP-B and C with the largest number of virulence-associated genes, except for genes *invA* and *sopE*, respectively. The highest diversity of VP was observed in the port of Lázaro Cárdenas, and in the regions of Morelia and Apatzingán. VP was unrelated to ST and serotype of tested strains. Because in all cases at least three virulence-associated genes were found, our results show that the studied strains of *S. enterica* have a high pathogenic potential, which is relevant for

public health given the presence of these strains in foodstuffs of daily consumption in the state of Michoacán.

## **POTENTIAL USE OF ESSENTIAL OILS FOR SURFACE DISINFECTION**

A. Vidács<sup>1</sup>, J. Krisch<sup>2</sup>, M. Chandrasekaran<sup>3</sup>, S. Kadaikunnan<sup>3</sup>, N. Alharbi<sup>3</sup>,  
C. Vágvölgyi<sup>1</sup>

<sup>1</sup>Department of Microbiology, University of Szeged, Szeged, Hungary

<sup>2</sup>Institute of Food Engineering, University of Szeged, Szeged, Hungary

<sup>3</sup>Botany and Microbiology Department, King Saud University, Riyadh, Saudi Arabia

### **Background**

Bacteria can attach to different surfaces and form biofilm causing hygiene problems. Microbes in biofilms are more resistant to antimicrobials than planktonic cells. The organic food industry can use only a limited number of disinfectants. Customers prefer “green technologies” in food production and processing thus there is a continuous need for the use of new natural compounds. Essential oils (EOs) have antimicrobial effect, are easy to produce and eco-friendly. Essential oils are hydrophobic and make the membrane more permeable and more hydrophobic on low pH.

### **Objectives**

In the present study we have investigated cinnamon, marjoram and thyme EOs (on the basis of our pre-study) against bacterial biofilm formation on different surfaces.

### **Methods**

MIC/MBC values of the EOs were determined against food spoilage bacteria: *E. coli*, *P. putida* and pathogens: *L. monocytogenes*, *S. aureus*, MRSA, *B. cereus* and *B. subtilis*. Disinfection time depending on pH and EO concentration was established. Biofilm elimination capacity of the EOs (24 and 168 hours old) from stainless steel and polypropylene surfaces (frequently used in food industry) was tested.

### **Conclusions**

Biofilm formation on plastic was stronger, than on stainless steel probably due to the roughness of surfaces. All investigated EOs had good biofilm removing effects. Best result was achieved with marjoram. In most cases bacterial reduction was 99.99%. EOs had also antibacterial effect on the tested isolates of MRSA and *L. monocytogenes*.

**EFFECT OF DRYING TREATMENT WITH POTASSIUM CARBONATE (K<sub>2</sub>CO<sub>3</sub>) ON SAFETY QUALITY OF DRIED FIG (FICUS CARICA L.), AS AN ALTERNATIVE TO TRADITIONAL PROCESS.**

M.C. Villalobos Rivera<sup>1</sup>, M.J. Serradilla<sup>2</sup>, L. Prieto<sup>1</sup>, S. Ruíz-Moyano<sup>1</sup>, M.J. Benito<sup>1</sup>, A. Hernández-León<sup>1</sup>, A. Martín<sup>1</sup>, M.G. Córdoba<sup>1</sup>

<sup>1</sup>*Producción Animal y Ciencia de los Alimentos, Escuela de Ingenierías Agrarias, Badajoz, Spain*

<sup>2</sup>*Área de Vegetales, Instituto Tecnológico Agroalimentario de Extremadura (INTAEX-CICYTEX), Badajoz, Spain*

**Background**

Sun drying process involves microbial risks such as fungal spoilage which could also produce mycotoxin.

**Objectives**

Therefore, the aim of this work was to study the effect of drying treatment with potassium carbonate (K<sub>2</sub>CO<sub>3</sub>) combined with osmotic solution on safety quality of fig from 'Calabacita' cultivar.

**Methods**

Two treatments of drying were used, firstly figs were dipped into K<sub>2</sub>CO<sub>3</sub> solution (10%) for 30 min, then in a sugar solution (50%) for 24h and finally drying at 65°C in a drier (TP). A second batch, with figs traditionally sun drying, was used as control (ND). Both batches of dried fig were packed in polyethylene punnets with a macroperforated film and stored at 20 °C for 90 days. Moisture loss was monitored during treatment and storage. Moreover, mold counts and mycotoxin presence were study during storage. Finally, molds were isolated and identified by sequence of the ITS region.

**Conclusions**

The moisture level in TP was 22% after two days of treatment, whereas similar value was obtained in ND after 12 days. Then, the used of potassium carbonate combined with sugar solution reduced significantly the time of drying. During storage, mold reached counts of 1.82 and 2.22 log CFU/g for TP and SD, respectively, at 30 days. *Cladosporium cladosporioides* was the main specie followed by *Aspergillus fumigates* in both batches, although they were found in greater number in ND. No mycotoxins were detected in both batches, however, the higher level of mold found in control batch, as well as longer drying process could suppose greater risk of mycotoxin production.

**PROFICIENCY TESTS FOR CAMPYLOBACTER ORGANIZED BY THE NATIONAL  
REFERENCE LABORATORY FOR FOOD OF ANIMAL ORIGIN IN POLAND  
DURING 2008-2014**

K. Wieczorek<sup>1</sup>, J. Osek<sup>1</sup>

<sup>1</sup>Department of Hygiene of Food of Animal Origin,  
National Veterinary Research Institute, Pulawy, Poland

**Background**

In accordance with the EU regulation No. 882/2004 National Reference Laboratories (NRL) are responsible for organization of proficiency tests (PT) for official food control laboratories. In Poland, NRL for *Campylobacter* was nominated at the National Veterinary Research Institute in Pulawy.

**Objectives**

The aim of the study was to evaluate the proficiency of laboratories by their participation in PTs towards determination of presence and number of *Campylobacter* in samples of food of animal origin.

**Methods**

The PTs were organized between 2008–2014 according to ISO/IEC 17043:2001, ISO/TS 22117:2010, and ISO 13528:2005 standards. In each year, two rounds of PT, i.e. one for detection and one for enumeration of *Campylobacter* in fresh poultry or pork meat, were performed. The samples were contaminated with the target *C. jejuni* or *C. coli* microorganisms at the levels between  $10^2$  -  $10^3$  cfu for 10 g or 25 g (detection) and  $<10^0$  –  $10^5$  cfu/g (enumeration). The samples were sent to the laboratories by the courier post in a cooled conditions which were obliged to begin the analyses within 24 h (detection) or immediately upon receiving the samples (enumeration). The number of official laboratories participated in each PT round varied from 7 (enumeration; year 2010) to 20 (detection; year 2012).

**Conclusions**

Most of the laboratories obtained satisfactory results (70 – 100% participants depending on the PT round) which indicated that food safety is under appropriate supervision. The PTs were the effective tool used by NRL to supervise the official food control laboratories in Poland.

**A NEW MULTIPLEX REAL-TIME PCR METHOD FOR DETECTION OF  
SALMONELLA SPP., LISTERIA MONOCYTOGENES AND VEROTOXIGENIC  
ESCHERICHIA COLI IN CARCASSES OF SLAUGHTERED ANIMALS**

*E. Denis<sup>1</sup>, K. Bielińska<sup>1</sup>, K. Wieczorek<sup>1</sup>, J. Osek<sup>1</sup>*

*<sup>1</sup>Department of Hygiene of Food of Animal Origin,  
National Veterinary Research Institute, Pulawy, Poland*

**Background**

*Salmonella* spp., *Listeria monocytogenes* and verotoxigenic *Escherichia coli* (VTEC) are among the most dangerous food-borne bacterial pathogens. Therefore, the availability of rapid and specific methods, especially to simultaneous detection of these pathogens, is needed.

**Objectives**

The objective of the study was to develop and evaluate a new TaqMan multiplex real-time PCR method for detection of *Salmonella* spp., *L. monocytogenes* and VTEC in slaughtered animals.

**Methods**

The method includes the enrichment step in Tryptone Soya Broth, DNA extraction and two real-time PCR reactions, one for detection of *invA* and *hly* genes of *Salmonella* spp. and *L. monocytogenes*, respectively, and another for detection of *vtx1*, *vtx2* and *eae* of VTEC. The results of validation showed a relative sensitivity, specificity and accuracy of 100% compared to the reference methods. The limit of detection (LOD) was established for 1 cfu per swab for *Salmonella* spp. and *L. monocytogenes* and 2 cfu for VTEC. The method developed was used to analyze 145 swabs collected at the slaughterhouse level from cattle, pigs and poultry carcasses. Among the 75 samples recovered from cattle 24 were positive for VTEC and two for *Salmonella* spp., whereas swabs from pigs (n=45), 3 and 2 samples, were positive for these pathogens, respectively. None of microorganisms tested were detected in 25 samples from poultry.

**Conclusions**

The method developed allows for rapid and specific detection of three food-borne pathogens in carcasses of slaughtered animals.

**PROPHAGE-ENCODED STAPHYLOCOCCAL ENTEROTOXIN A: REGULATION OF PRODUCTION IN DIFFERENT STAPHYLOCOCCUS AUREUS STRAINS**

N. Zeaki<sup>1</sup>, Y. Budi Susilo<sup>1</sup>, A. Pregiel<sup>1</sup>, P. Rådström<sup>1</sup>, J. Schelin<sup>1</sup>

<sup>1</sup>Applied Microbiology, Lund University, Lund, Sweden

**Background**

Staphylococcal Food Poisoning (SFP) is one of the most common food-borne intoxication diseases, caused by enterotoxins produced by *Staphylococcus aureus*. 21 staphylococcal enterotoxins (SEs) or enterotoxin-like proteins (SEIs) have been recognized until now with enterotoxin A (SEA) being most frequently implicated in SFP outbreaks. SEA is encoded by the *sea* gene, located on the genome of *Siphoviridae* bacteriophages and unlike most other enterotoxins is not regulated by the accessory gene regulator (*agr*). Previous studies have shown that the regulation of the *sea* gene in the different SEA-producing strains is partially linked to the lifecycle of the prophages carrying the gene. Differences have been observed on the levels of toxin produced among the strains, and are hypothesized to originate from the *Siphoviridae* phages.

**Objectives**

With this study, we aim to get a better insight on the regulation of the *sea* gene by understanding the level on which the phage life-cycle affects SEA production.

**Methods**

We study five *S. aureus* strains under optimal and chemically induced conditions and monitor the replication of the phage in connection with *sea* gene copies and mRNA transcript levels. Furthermore, we follow the extracellular toxin levels and estimate phage titers.

**Conclusions**

The data obtained have showed a distinct correlation between replicating phage copy levels and *sea* gene copy levels in both growth conditions, linking phage induction with the increase observed on SEA levels. The significance of these findings lays in the realization that any treatment potentially inducing replication of the *sea*-carrying prophages, will enhance the risk for SFP.

## **LISTERIA MONOCYTOGENES CONTAMINATION IN COLD-SMOKED FISHERY PRODUCTS SOLD IN AUSTRIA**

M. Zunabovic<sup>1</sup>, U. Zitz<sup>1</sup>, M. Günther<sup>1</sup>, B. Bromberger<sup>1</sup>, W. Kneifel<sup>1</sup>, K.J. Domig<sup>1</sup>

<sup>1</sup>University of Natural Resources and Life Sciences Department of Food Science and Technology, Institute of Food Science, Vienna, Austria

### **Background**

Smoked salmon as a ready-to-eat (RTE) food can be typically contaminated with *Listeria monocytogenes*, albeit in low numbers. The legal safety limits for RTE are set in the European Commission Regulation No. 2073/2005 and are particularly exceeded by RTE fishery products and cheeses.

### **Objectives**

The aim of the present study was to investigate the *L. monocytogenes* contamination rates in cold-smoked fishery products in Austria over a one-year period (2013-2014).

### **Methods**

A total of 250 RTE samples were collected in the region of Vienna and analysed at the end of shelf-life. The influence of physico-chemical properties (aw, pH and phenolic content) on the prevalence was also assessed. Isolates were characterized by multiplex PCR serogrouping and rep-PCR. The biofilm forming ability of *L. monocytogenes* isolates was assessed by the crystal violet method and a modified fluorescence microscopy-based technique.

### **Conclusions**

Among the tested fishery products 23% were contaminated with *L. monocytogenes* which correlates with international literature data. Enumeration results ranged from 1 to 760 CFU/g. Serogrouping achieved that 87% of isolates have been classified to 1/2a, 3a serotype and others mainly belonged to groups 4b, 4d, 4e and 1/2b, 3b, 7. Biofilm forming ability could be determined for some isolates when compared with *L. monocytogenes* reference strains representing different serotypes and sources. The physico-chemical data revealed a strong variability within the smoked fishery product category. These discrepancies show the need for factory specific analysis of *L. monocytogenes* growth potential in smoked fishery products in order not to misinterpret the risk-categorization of such products.

**ACTINOMYCETES AS BIOCONTROL AGENTS IN GRAPEVINE WOOD DISEASES: A GOOD TENANT IN THE ROOT?**

J.M. Álvarez-Pérez<sup>1</sup>, S. González-García<sup>1</sup>, R. Cobos<sup>1</sup>, E. Garzón-Jimeno<sup>1</sup>,  
C. Barreiro<sup>2</sup>, J.J.R. Coque<sup>1</sup>

<sup>1</sup>Grapevine diseases, Research Institute of Vineyard and Wine. University of León, Leon, Spain

<sup>2</sup>Proteomics, INBIOTEC (Instituto de Biotecnología de León), Leon, Spain

**Background**

One of the most important problems in wine production regions is the premature death of young grapevines. It is due mainly by the infection of fungus that produces wood diseases, like Petri disease and black-foot disease. There are two principal ways to infection. One is the 'industrial process' in order to produce the commercial grafted plants. Another possibility is associated to 'natural processes' when the infection is produced on the field mainly by the pruning wounds or by natural infection through the root system. In fact, most of pathogens associated to these diseases are able to infect the grapevine through the root system.

**Objectives**

The main objective of this study is the use of actinomycetes isolated from the rhizosphere of young grapevines as biocontrol agents (BCAs) in order to reduce or avoid the infection through the root system by pathogenic fungus.

**Methods**

Several actinomycetes were isolated from rhizosphere of young plants of *Vitis vinifera*. These were unequivocally identified by molecular methods. Their capability as biocontrol agent were bioassayed *in vitro* against several pathogenic fungus. Those showing the best capabilities were selected for 'field studies' on grafted plants in order to know the real behaviour as BCAs.

**Conclusions**

Several actinomycetes have shown a good capability to reduce the infection rate through the root system of several fungal pathogens causing decline of young grapevines. They could be a good alternative in order to avoid chemical products in the establishment of new vineyards.

### Fungal bacterial interactions

#### EFFECT OF SOME LIGNICOLOUS EDIBLE AND MEDICINAL FUNGAL SPECIES AGAINST VIRAL (BACTERIOPHAGE) AND BACTERIAL DNA

M. Karaman<sup>1</sup>, D. Rajkovic<sup>2</sup>, P. Knezevic<sup>3</sup>, D. Obreht<sup>3</sup>, L. Janjusevic<sup>3</sup>, K. Tesanovic<sup>3</sup>, M. Matavulj<sup>3</sup>

<sup>1</sup>Department of Biology and Ecology, Faculty of Sciences University of Novi Sad, Novi Sad, Serbia

<sup>2</sup>Department of Biotechnology, Institute of Field and Vegetable Crops, Novi Sad, Serbia

<sup>3</sup>Faculty of Sciences University of Novi Sad, Department of Biology and Ecology, Novi Sad, Serbia

#### Background

Nowadays, when high resistance against common antibiotics is evident, a great attention has been focused on some new natural sources of antimicrobial agents, including mushrooms. Medicinal mushroom species mostly belong to lignicolous (wood-decaying) fungi and represent particularly promising organisms with bioactive compounds acting as antimicrobials.

#### Objectives

In the present study, the genotoxic effect of 80% ethanol and 70% methanol, extracts of some lignicolous edible and medicinal fungal species: *Agrocybe aegerita*, *Meripilus giganteus*, *Coriolus versicolor*, *Daedaleopsis confragosa*, and *Stereum fuscum* were investigated. *Ganoderma applanatum* extract was prepared in ethanol after hydrodistillation procedure. They have been tested against bacteriophage DNA ( $\delta$  - Podoviridae and  $\sigma$ -1 - Siphoviridae), as well as against DNA extracted from *Escherichia coli* (ATCC 25922) and *Micrococcus flavus* ATCC 40240.

#### Methods

The extracted DNAs from viruses and bacteria were analyzed after treatment with fungal extracts (initial concentrations 200 mg/ml and 500 mg/ml) after 24 h in broth medium. Activity of the analyzed extracts on DNA fragmentation was visually determined on agarose gel after electrophoresis.

#### Conclusions

After 24h, extracts of *C. versicolor* and *G. applanatum* lead to the disintegration of *E. coli* DNA, while the extract of *M. giganteus* showed slight effect. All extracts showed disintegration effect against both phage DNAs, except extract of edible species *A. aegerita*. The other extracts give effect in concentration 1:100, except *S. fuscum* and *C. versicolor* against  $\sigma$  -1 phage DNA. The phage DNAs were not disintegrated with

any extract in concentration 1:10 000. The results showed that some higher concentrations of extracts possess genotoxic activity.

### Fungal bacterial interactions

#### ANTIBACTERIAL AND GENOTOXIC ACTIVITY OF FOMES FOMENTARIUS (L.) FR. AND PLEUROTUS OSTREATUS (JACQ.) P. KUMM. FUNGAL EXTRACTS

L.J. Janjusevic<sup>1</sup>, M. Karaman<sup>1</sup>, D. Obreht<sup>1</sup>, P. Knezevic<sup>1</sup>, K. Tesanovic<sup>1</sup>, M. Matavulj<sup>1</sup>

<sup>1</sup>Department of Biology and Ecology, Faculty of Sciences-University of Novi Sad, Novi Sad, Serbia

#### Background

Since fungi share common microorganisms such as *E. coli*, *S. aureus* and *P. aeruginosa* with animals and humans, it is believed that the humanity will meet more benefits from fungi and mushrooms, as antibiotics producers, than from plants. Many lignicolous species have been detected to act as antimicrobials until now, but activities are mostly influenced by fungal strain specificities and habitat characteristics, including geographic position.

#### Objectives

Since antibiotic mechanisms of fungi are still unclear, the aim of this investigation was to find connection between antibacterial and DNA genotoxic activity. Two kinds of extracts were prepared from fresh samples of autochthonous fungal species: *Fomes fomentarius* and *Pleurotus ostreatus* after simple extraction and after pouring with liquid nitrogen in order to disintegrate sporoderm.

#### Methods

Antibacterial testing was done with 70% MeOH extracts using macro and micro-dilution methods. Genotoxic effect against two bacterial strains *E. coli* and *M. luteus* was checked with 20%, 10% for *P. ostreatus* and 10%, 2.5% for *F. fomentarius* extract concentration. After 24h incubation, isolated DNA was applied on agarose gel electrophoresis.

#### Conclusions

The best antibacterial activity was obtained for *F. fomentarius* extracts mostly against Gram positive strains: *M. flavus*<sup>ATCC40240</sup>, *S. aureus*<sup>ATCC25923</sup>, *C. perfringens*<sup>ATCC19404</sup> and *B. subtilis*<sup>ATCC6633</sup> and gram negative *E. coli*<sup>ATCC25922</sup>. Significant increase in the size of bacterial cells was detected.

The MIC showed significant *E. coli* DNA fragmentation, indicating that this can be a possible mechanism of antibacterial activity, but also that these extracts can have a potential genotoxic activity which should be further examined.

<sup>2</sup>Laboratory of Biogeosciences, Institute of Earth Sciences, University of Lausanne, Lausanne, Switzerland

<sup>3</sup>Vital-IT group, Swiss Institute of Bioinformatics, Lausanne, Switzerland

<sup>4</sup>Laboratory of Eco-ethology, Institute of Biology, University of Neuchâtel, Neuchâtel, Switzerland

#### **Background**

Fungi and bacteria have a long co-evolutionary history in terrestrial ecosystems. In soils, they are the basis for nutrient recycling. Therefore, not only do they co-exist, but they are also potential competitors for resources. In our laboratory, it was shown that the bacterium *Pseudomonas putida* benefits from interaction with fungi by using the so-called “Fungal Highways” to disperse in porous unsaturated soil-like media. Dispersal allows the bacteria to reach nutrient sources, as their mobility is limited in these conditions. However, the direct fitness benefit for the transporting fungi remains unknown. Until now, a long-term benefit was shown for the ectomycorrhizal and saprophytic fungus *Morchella crassipes*, which acted as a farmer of the dispersing bacteria and storing bacterial carbon into resting structures.

#### **Objectives**

We focus on the investigation of the benefit obtained by fungi during dispersal of bacteria.

#### **Methods**

Experiments were all undertaken on skimmed-milk agar medium (SMA; protein as N source) to see how extracellular proteolytic activity is used to access organic nitrogen. In addition, the fungal enzymes responsible were characterized according to their activity.

#### **Conclusions**

We have determined that fungal proteolysis can be enhanced by the presence of *P. putida* even when fungal cells are removed. The enhanced activity requires living bacterial cells, which is also observed for other bacteria dispersing in the fungal

mycelia. In conclusion, enhancement of proteolytic activity seems to be a direct fitness benefit for the interaction of *M. crassipes* with soil bacteria.

**Fungal bacterial interactions**

## **ENDOPHYTIC BACTERIA OF TOMATO: A SOURCE OF ANTIFUNGAL AND ANTIBACTERIAL COMPOUNDS**

A. Ruaud<sup>1</sup>, B. Nieuwesteeg<sup>1</sup>, C. Papazlatani<sup>1</sup>, H. Gibriel<sup>1</sup>, R. Nijland<sup>1</sup>

<sup>1</sup>Laboratory of Phytopathology, Wageningen University, Wageningen, Netherlands

### **Background**

Many microorganisms are found inside various plant tissues. There, they not only compete with the plant immune system, but also with other endophytes and pathogenic microorganisms. We study endophytes of two underexplored above ground niches inside the tomato plant, the xylem and the leaf apoplast. Xylem vessels are the habitat of vascular wilt causing pathogens such as the bacterium *Clavibacter michiganensis* and the fungus *Verticillium dahliae*, whereas the leaf apoplast harbours the leaf mould *Cladosporium fulvum* and the late blight oomycete *Phytophthora infestans*.

### **Objectives**

Study the mechanism of *in planta* inter-microbe competition. Identify biocontrol species

### **Methods**

Endophytic bacteria were isolated from tomato xylem and leaf apoplastic space. Colonies were picked after incubation on TSA for 2-10 days at 25°C. Isolated strains were inoculated on a lawn of fungal, bacterial or oomycete plant pathogens and the release of antimicrobial compounds was scored. Garden cress was inoculated with selected strains. Seedling development was followed, and after 20 days endophytic bacteria were re-isolated from the stems.

### **Conclusions**

We isolated >120 tomato associated bacteria. More than half have antifungal, antibacterial and/or anti-oomycete properties during *in vitro* co-culture. >75% of species isolated from above ground parts of tomato were gram-positive. Garden cress was inoculated with strains with strong antifungal properties. Most strains promoted plant growth, and could be re-isolated from the stems, indicating a true endophytic lifestyle. Currently we are elucidating the antagonistic mechanisms and testing their potential for inhibiting pathogens *in planta*. In conclusion, the above

ground tomato endophytic bacteria are a promising source of antimicrobial compounds.

## **EFFECT OF BACTERIAL DISPERSAL ON THE BIOAVAILABILITY OF SEMIVOLATILE ORGANIC CONTAMINANTS**

S. Otto<sup>1</sup>, T. Banitz<sup>2</sup>, K. Johst<sup>2</sup>, T. Hübschmann<sup>1</sup>, H. Harms<sup>1</sup>, L.Y. Wick<sup>1</sup>

<sup>1</sup>*Environmental Microbiology, Helmholtz Centre for Environmental Research, Leipzig, Germany*

<sup>2</sup>*Ecological Modelling, Helmholtz Centre for Environmental Research, Leipzig, Germany*

### **Background**

Contaminants bound to biogeochemical interfaces (BGI) are only hazardous if they become bioavailable. Therefore, the most effective remediation technique should lead to an optimal coverage of BGI with degrading microorganisms in order to prevent contaminant release to the environment. Simultaneously they should reduce the contaminant concentration at its source.

### **Objectives**

Here, we investigated the impact of bacterial dispersal on BGI on the outgassing of semivolatile phenanthrene (PHE). We tested the hypothesis whether the presence of previously described fungal transport networks ('fungal highways') of bacteria leads to: (i) bacterial distribution along the transport network, (ii) efficient bacterial distribution on the surface, and (iii) an increased biomass production fostering the degradation of PHE, that are released from the system.

### **Methods**

We designed a laboratory microcosm that mimicked a continuous PHE release to a model surface (agar) in the presence and absence of model dispersal networks (glass fibers) that facilitated the transport of the poorly motile PHE-degrading *Pseudomonas fluorescens* on agar surfaces.

### **Conclusions**

We observed that the presence of the dispersal network resulted in (i) an increased spatio-temporal spreading of bacteria, (ii) an increased bacterial coverage and growth on the agar surface, and (iii) a subsequent effective degradation of outgassing PHE and effective reduction of PHE contamination beyond the PHE hotspot. Our data suggest that fungal mycelia may promote the formation of an adapted microbial population that will degrade hazardous molecules that desorb from the contaminant source. Potentially, such an activity produce no emission of contaminants to the pore and groundwater, and hence, to higher organisms.

**STUDYING INITIAL FUSARIUM GRAMINEARUM-BIOCONTROL PSEUDOMONAS FLUORESCENS INTERACTIONS IN AN ESTABLISHING MICROTITER PLATE MICROCOSM SYSTEM**

H. Shahbazi<sup>1</sup>, K. Behboudi<sup>1</sup>, K. K. Brandt<sup>2</sup>, S. Olsson<sup>2</sup>

<sup>1</sup>Department of Plant Pathology,

College of Agriculture and Natural Resources University of Tehran, Karaj, Iran

<sup>2</sup>Department of Plant and Environmental Sciences, University of Copenhagen, Frederiksberg, Denmark

**Background**

The hyphosphere constitutes a microenvironment in which enzymes, metabolites and antibiotics secreted by the fungi are abundant which could attract bacteria.

**Objectives**

We here describe the first steps in establishing a microcosm system to study fungal-bacterial interaction under low-nutrient conditions emulating natural habitats like soil or the rhizosphere, then study fungal-bacterial interactions. *Fusarium graminearum* head blight in cereals was used as a model fungus, whereas *Pseudomonas fluorescens* strains P13, UTPF105, UTPF127, UTPF125 and B4 identified as biocontrol agents from Iranian soils were used as model bacteria.

**Methods**

For establishing this microcosm, 1000 spores of *F. graminearum* with 100 µl diluted medium was added to each microtiter well and incubated for 38 h at 20°C then the media was removed and inoculated with 100µl of 10<sup>4</sup>/ml bacterial suspension. After 24 h further incubation the microcosm system was stained by SYBR Green (SG) and Calcofluor white (CW) fluorescent stains. SG binds DNA and absorbs blue light and emits green light ( $\lambda = 520\text{nm}$ ). CW binds to chitin. Some photos of each CW (under UV light) and SG (under blue light) wells were taken. Both blue hyphae and green DNA signals were analyzed by ImageJ software. The experiment was arranged as randomized complete design with 4 replications. A Duncan test with a probability of 0.01 was used to show significant differences between treatments.

**Conclusions**

CW result showed that the biocontrol strains decreased fungal growth. In this reduction, UTPF125 was more successful. SG results showed that in a same hyphosphere, growth of different bacterial strains were significantly different.

## **A MECHANISM OF ALTERNATIVE SPLICING IN FILAMENTOUS FUNGI**

N. Ág<sup>1</sup>, M. Flippin<sup>1</sup>, C. Scazzocchio<sup>2</sup>, L. Karaffa<sup>1</sup>, E. Fekete<sup>1</sup>

<sup>1</sup>Department of Biochemical Engineering, University of Debrecen, Debrecen, Hungary

<sup>2</sup>Department of Microbiology, Imperial College, London, United Kingdom

### **Background**

Alternative intron splicing could lead to frame-shifted ORFs so that peptides with different terminal extensions can be produced. Alternative splicing of introns bordered by coding exons may yield the presence or absence of additional domains. We have found a *Penicillium chrysogenum* gene that yields two transcripts of different size.

### **Objectives**

An alternative intron gives rise to the two mature mRNAs using alternative, coupled lariat-branchpoint domain/acceptor sites. In *P. chrysogenum*, the short variant is 213 nt, the long variant is 891 nt long. Both transcripts yield a full-length protein. We found the presence of one canonical donor and one canonical lariat-branchpoint domain/acceptor couple within the short variant of the alternative intron, potentially defining an “internal” intron of 64 nt. We investigated whether this “internal” intron produces splicing intermediates.

### **Methods**

By sequencing cloned RT-PCR amplification products, we have elucidated the sequences of the mature mRNAs and that of splicing intermediates in *P. chrysogenum* and *Aspergillus nidulans*.

### **Conclusions**

We showed that contrary to “intron definition theory”, the “external” (5') donor was not used with the most 5' (“internal”) acceptor site. The “internal” (3') donor was not used with the most distal (most 3') acceptor site. It is the “internal” intron that is spliced alternatively using the 3' donor and either of the closely neighbouring lariat-domain/acceptor couples. The identity of the (more outward) acceptor used for the subsequent removal of the “external” intron and hence, the peptide ultimately produced, are thus primarily determined by the outcome of the first, alternative splicing reaction.

**Fungal development**

## **REGULATION OF THE CUTINOLITIC SYSTEM IN ASPERGILLUS NIDULANS**

E. Bermudez<sup>1</sup>, C. Peña<sup>1</sup>, A. Farrés<sup>1</sup>

<sup>1</sup>*Food and Biotechnology,*

*Facultad de Química Universidad Nacional Autónoma de México, Mexico City, Mexico*

### **Background**

Cutinases play a role in plant pathogenesis as they degrade cutin, a structural lipid component of plant cuticle. They also act on short- and long-chain fatty acids, a feature that makes them suitable for biotechnology applications (Carvalho C, 1998). In *Aspergillus nidulans* genome there are four putative genes of cutinases (ancut1,2,3, and 4) and neither their role in cutin degradation or the expression conditions and their regulation are well understood, although it may be related to lipid metabolism (Hynes MJ, 2006).

.

### **Objectives**

- Determine the expression levels of the cutinases encoded in the *A. nidulans* genome in response to different carbon sources that may act as repressors or inducers of the enzymes.
- Study the effect of two global TF (farA, farB) involved in lipid metabolism over the cutinase expression.
- Propose a regulation model of the cutinolytic system.

### **Methods**

*Aspergillus nidulans* was grown in minimal medium and different carbon sources were used. Mycelium was used for RNA's extraction with TRIzol. cDNA was synthesized using dT primers and Reverse Transcriptase. Finally the expression level of the genes was measured in Multiplex qRT-PCR assays and normalized with an endogenous gene. These expression levels were compared with the enzyme activity found in the supernatants in all the conditions studied.

## Conclusions

*ancut1*, *ancut2* and *farA* were upregulated with cutin and cutin monomers and showed CCR in presence of glucose. *ancut3* and *farB* were expressed constitutively and *ancut4* wasn't detected in any condition. Cutinase expression in *A. nidulans* resembles that found for *F. solani* (Li D, 1997).

**RNA-MEDIATED SILENCING OF A GENE ENCODING FOR A ZN(II)<sub>2</sub>CYS<sub>6</sub> PROTEIN CHANGES THE PHENOTYPE OF PENICILLIUM ROQUEFORTI**

R. Chavez<sup>1</sup>, C. Gil-Duran<sup>1</sup>, J.F. Rojas-Aedo<sup>1</sup>, E. Medina<sup>1</sup>, R.O. Garcia-Rico<sup>2</sup>, I. Vaca<sup>3</sup>

<sup>1</sup>Departament of Biology, Universidad de Santiago de Chile, Santiago, Chile

<sup>2</sup>Departament of Microbiology, Universidad de Pamplona, Pamplona, Colombia

<sup>3</sup>Departament of Chemistry, Universidad de Chile, Santiago, Chile

**Background**

The fungus *Penicillium roqueforti* has been poorly studied. Currently, we are studying a strain of this fungus that contains a dominant active Gai protein. This strain shows several phenotypic alterations compared with the wild-type strain. In a preliminary study, we observed a cDNA sequence differentially expressed in the wild-type strain. This sequence matched an unnamed ORF from *P. roqueforti* that encodes a putative Zn(II)<sub>2</sub>Cys<sub>6</sub> protein of unknown function. Proteins containing Zn(II)<sub>2</sub>Cys<sub>6</sub> domains are exclusively found in fungi, but few of them have been functionally characterized.

**Objectives**

To characterize a gene from the filamentous fungus *Penicillium roqueforti* that encodes a Zn(II)<sub>2</sub>Cys<sub>6</sub> protein, whose function to date remains unknown. We have named this gene *pcz1*.

**Methods**

*pcz1* was silenced using RNAi-silencing technology. Two transformants (named M9 and M11) showed dramatic reductions in the levels of *pcz1* transcript, confirming the successful knockdown of the gene. In these transformants, the apical extension rates, the conidiation, and the conidial germination were measured by standard methodologies.

**Conclusions**

The silencing of *pcz1* in the transformants altered the normal phenotype of *P. roqueforti*. **Specifically**, RNA-mediated silencing of *pcz1* resulted in the strong repression of conidiation, decreased apical growth, and the promotion of conidial germination in *P. roqueforti*, even in the absence of a carbon source. Our results suggest that *pcz1* may be involved in fungal development. Specifically, it may be a positive regulator of conidiation and apical growth, but it may be a repressor of conidial germination in *P. roqueforti*.

**PROMOTER ANALYSIS OF AN ACIDIC LACCASE GENE EXPRESSED BY  
EXTERNAL PH IN AN INKY CAP, COPRINELLUS CONGREGATUS**

H. Choi<sup>1</sup>

<sup>1</sup>*Biochemistry, Kangwon National University, Chuncheon-Si Gangwon-Do, Korea*

**Background**

*Coprinellus congregatus*, generates mushrooms from dikaryotic mycelia, and this fungus produces several laccases: hyphal tip laccase and primordial laccase and they are not secreted outside of cells. When the dikaryon was grown in an acidic medium (pH 4.0-4.5), a new laccase was secreted into the culture supernatant. We have also cloned its genomic and cDNA genes, and also confirmed its expression only under acid condition by Northern blot analysis.

**Objectives**

There must be two responsive regions in the promoter region which are related to the signals that the mycelia is a dikaryon and is under acid stress respectively. In order to determine the responsive domain in the promoter, a recombinant construct having the acidic laccase gene promoter and green fluorescent protein (GFP) gene was generated.

**Methods**

The construct was introduced into *C. congregatus* monokaryones (a1 and a2), and the transformants were selected. Heterozygotic and homozygotic transformants were generated by mating proper partners. These transformants were transferred to the acid liquid media. Fungal cells were collected and they were used for the analysis of the promoter expression under confocal microscope and/or real time RT-PCR.

**Conclusions**

Homozygotic transformants showed more than 25 times higher expression than the negative control: this system helped the promoter domain analysis. Different lengths of acid laccase gene promoter-GFP will be constructed, and these will be introduced to the monokaryons. When the transformants carrying these various lengths of promoter

were analyzed at the acid culture conditions, the responsible doamins for dikaryon and acid stress will be determined.

## **TRANSCRIPTIONAL LANDSCAPE OF A MODEL MUSHROOM SCHIZOPHYLLUM COMMUNE**

*I. Choi*<sup>1</sup>, *B. Min*<sup>1</sup>, *H. Park*<sup>1</sup>, *R. Ohm*<sup>2</sup>, *I. Grigoriev*<sup>3</sup>

<sup>1</sup>*Biotechnology, Korea University, Seoul, Korea*

<sup>2</sup>*Department of Microbiology, Utrecht University, Utrecht, Netherlands*

<sup>3</sup>*Fungal Genome Program, Joint Genome Institute, Walnut Creek, USA*

### **Background**

Transcription start site (TSS) sequencing gives a high resolution map of transcription initiation region for identifying promoters and fine-tuned transcriptional regulation mechanism. Although TSSs of various eukaryotic model organisms have been revealed, no species belonging to Basidiomycota has been known yet.

### **Objectives**

In order to understand transcriptional regulation in terms of promoters and transcriptional regulation on growth conditions, we report the first TSS analysis of Basidiomycota, the lignin-degrading fungus *Schizophyllum commune*

### **Methods**

Total 8.5 million RNA reads were generated by rapid amplification of cDNA ends (RACE) from two different growth conditions (cellulose or glucose as a sole carbon source) and mapped into the genome to allocate the transcription start sites.

### **Conclusions**

The positions of transcript head for the 4,959 genes were retrieved from both growth conditions. Comparing to the features of promoters found in eukaryotic model organisms, TSS distribution of *S. commune* were categorized into distinct groups such as single start sites ('sharp' promoter), multiple start sites ('broad' promoter) or mixed. To associate these features with DNA motifs in promoters, we examined the upstream 500 bp region of all genes. We found 16 motifs in the 'sharp' promoter upstream regions including typical TATA-box. The TSS analysis provides not only a basis for understanding of promoter structures but also a principle to build synthetic promoter construction for desired gene expression in *S. commune*.

### **THE PREVALENCE OF PNEUMOCYSTIS JIROVECII IS CHANGED?**

S. Ghafourian<sup>1</sup>, N. Sadeghifard<sup>2</sup>, M. Taherikalan<sup>2</sup>, E. Aboualigalehdar<sup>2</sup>

<sup>1</sup>Department of Medical Microbiology and Parasitology Faculty of Medicine and Health Sciences, University Putra Malaysia, putra, Malaysia

<sup>2</sup>Clinical Microbiology Research Center, Ilam University of Medical Sciences Ilam Iran, Ilam, Iran

#### **Background**

*Pneumocystis pneumonia* (PCP) that is caused by *Pneumocystis jirovecii* is prevalent in HIV-infected patients. Pneumocystis colonization of *Pneumocystis* is associated with airway inflammation and obstruction.

#### **Objectives**

The current study was conducted to identify the prevalence of *P. jirovecii* in suspected tuberculosis (TB) patients and four HIV positive patients in Ahvaz, Iran.

#### **Methods**

111 suspected TB positive patients and four HIV patients were investigated for *P. jirovecii* identification from Bronchoalveolar lavage specimens. The specimens were subjected for Grocott's methenamine silver (GMS) staining and then DNA extraction following Nested-PCR with specific primers. The PCR product then subjected for sequencing.

#### **Conclusions**

The findings demonstrated 50% of HIV positive patients were contaminated with *P. jirovecii* and 2 remaining patients showed negative results. In 111 suspected TB positive patients 25.2% were positive for TB, which 9 samples were positive for PCP by *P. jirovecii*. In negative TB patients, 19 positive *P. jirovecii* were identified. The analysis by Chi-square demonstrated that there was no significant difference between sex and presence of *P. jirovecii*. The current statistical analysis also presented no significant difference between TB and *P. jirovecii*. Finally, the GMS only detected *Pneumocystis jirovecii* in three patients. Our findings demonstrated high prevalence of *P. jirovecii* in Ahvaz which was more than the previous reports in Iran. Our investigation revealed that the *Pneumocystis jirovecii* is important in all respiratory tract infected patient not only in HIV or TB patients.

**AXL2, THE HOMOLOGUE OF THE YEAST BUD SITE SELECTION PROTEIN  
AXL2P AFFECTS ARTHROSPORE FORMATION IN ACREMONIUM  
CHRYSOGENUM**

J. Kluge<sup>1</sup>, U. Kück<sup>1</sup>

<sup>1</sup>Department of General und Molecular Botany, Ruhr-University Bochum, Bochum, Germany

**Background**

*Acremonium chrysogenum* is the natural producer of the  $\beta$ -lactam antibiotic cephalosporin C. Due to its antibacterial activity against gram-positive and gram-negative bacteria, this  $\beta$ -lactam antibiotic is of great biotechnological and medical relevance. To optimize cephalosporin C production efficiently, continuous and directed improvement of industrial strains is required.

**Objectives**

A typical morphological feature of *A. chrysogenum* is the fragmentation of vegetative mycelium into arthrospores. These are uni- or binuclear cells, which develop during a prolonged cultivation under limited nutrient supply. Due to the known correlation of cephalosporin C production and arthrospore formation, we are interested in the identification of specific regulatory factors affecting both, cephalosporin C biosynthesis and morphological development. Here, we present a functional characterization of Axl2 in *A. chrysogenum*, a homologue of the yeast bud site selection protein Axl2p. In addition to that we are interested in the localization of Axl2 and other proteins of the bud site selection complex to verify their direct regulation of arthrospore formation.

**Methods**

Homologous recombination through split-marker approach; microscopic analysis

**Conclusions**

An *axl2* deletion strain of *A. chrysogenum* shows an accelerated arthrospore formation in comparison to its recipient strain. Therefore it might act as putative regulator of septation processes of fungal hyphae and consequently affect the arthrospore formation. To further investigate this developmental process we were able to establish the visualization of filamentous actin with the live cell marker Lifeact.

**STUDY OF COLONIZATION MECHANISMS OF CONSTRUCTION AND DECORATION PRODUCTS BY MICROMYCETES APPLIED TO THE DEVELOPMENT OF A PREVENTIVE TREATMENT**

I. LACAZE<sup>1</sup>, S. MOULARAT<sup>1</sup>, M. DRAGHI<sup>1</sup>, E. ROBINE<sup>1</sup>, P. SILAR<sup>2</sup>

<sup>1</sup>Health and Comfort, CSTB, Champs-sur-Marne, France

<sup>2</sup>Matériaux et biomatériaux innovants, LIED, Paris, France

**Background**

In nature, saprotrophic fungi have an essential ecological role in decomposition of organic matter. In soils, they break down material like leaves, wood, dead bodies, etc. Fungal colonization in natural environments requires advanced functional relationships, including various antagonisms and synergisms, between the different components of the biotope. Colonization can be described, analyzed at different scales (macroscopic and molecular) and modeled. In indoor environment, fungi find niches favorable to their development, but are most often undesirable. Indeed, micromycetes induce pathologies to the occupants (allergies, poisoning and infections) and can also cause irreversible damages to the materials they infest. Colonization of different man-made substrates (construction and decoration products) by mold is insufficiently described to develop colonization models: Is artificial substrate colonization done serendipitously or is it determined like in natural environment by a defined succession of fungi driven by antagonisms and synergisms? A better knowledge of the dynamic of fungal colonization would be helpful to imagine preventive strategy for health and artifacts preservation.

**Objectives**

In this context, our research in microbial ecology aims to describe and understand the fungal colonization mechanisms in enclosed spaces.

**Methods**

First, a macroscopic characterization of the fungal succession on two artificial substrates has been made by culture and molecular methods. Secondly, Volatile Organic Compounds (VOC's) emitted by microfungi according to the growth substrates have been explored.

**Conclusions**

This new knowledge will offer alternatives to slow and limit fungal growth on building products to the use of traditional biocides.

## **IDENTIFICATION OF A SECOND LACTOSE PERMEASE GENE (LACPB) IN ASPERGILLUS NIDULANS**

A. Orosz<sup>1</sup>, L. Kulcsár<sup>1</sup>, E. Fekete<sup>1</sup>, M. Flippin<sup>1</sup>, L. Karaffa<sup>1</sup>

<sup>1</sup>Department of Biochemical Engineering, University of Debrecen, Debrecen, Hungary

### **Background**

For most micro-organisms, lactose is a gratuitous carbon source that is slowly assimilated. In the filamentous fungus *Aspergillus nidulans*, lactose hydrolysis occurs intracellularly. Transport of lactose, which was previously shown to involve the lactose permease LacpA, is the limiting step in its catabolism in *A. nidulans*. Since *lacpA* deletion mutants are still able to grow on lactose, we assumed the existence of a second, physiologically relevant uptake system.

### **Objectives**

Identification and characterization of the second lactose permease gene (*lacpB*, locus AN2814) in *A. nidulans*, which encodes a structural paralog of LacpA.

### **Methods**

Single (*lacpB*) and double (*lacpA*, *lacpB*) lactose permease deletion mutants were created to test their phenotype (both growth and carbon source uptake) on solid and liquid media. Transcription profiles of *lacpB* and *lacpA* were also compared using Northern blot analyses.

### **Conclusions**

Growth of *lacpB*-single and *lacpA/lacpB* double deletants was strongly reduced on lactose on solid media, while in submerged cultures, the lactose phenotype was even more pronounced. Expression of the two *lacp* genes differed markedly. In addition to lactose, *lacpA* transcription also responded to D-galactose and L-arabinose, while *lacpB* was found induced by cellobiose, sophorose as well as lactose. Neither of the genes appeared to be expressed on D-glucose, D-xylose or D-mannose. We conclude that *lacpA* and *lacpB* are jointly responsible for wild-type lactose uptake by *A. nidulans*.

**CONIDIAL ANASTOMOSIS TUBES AND HETEROKARYOSIS IN THE ASEXUAL PLANT PATHOGENIC ASCOMYCETE VERTICILLIUM DAHLIAE**

I.A. Papaioannou<sup>1</sup>, M.A. Typas<sup>1</sup>

<sup>1</sup>*Faculty of Biology Department of Genetics & Biotechnology, University of Athens, ATHENS, Greece*

**Background**

*Verticillium dahliae* is a ubiquitous soilborne fungus that is known to reproduce strictly asexually. Therefore, different strains can only exchange and recombine genetic information through the parasexual cycle, starting with fusion (anastomosis) between hyphae of different genotypes to the formation of heterokaryons. Recently it was shown that parasexuality may alternatively begin in other fungi with fusion between conidial germlings via conidial anastomosis tubes (CATs).

**Objectives**

(i) To explore the possibility of self-/non-self fusion between *V. dahliae* germlings via CAT formation and study CATs' physiology, (ii) to study nuclear dynamics and heterokaryon formation through CATs, (iii) to identify signaling pathways that are required for CAT formation in *V. dahliae*.

**Methods**

(i) Live-cell imaging and analysis of fixed germling preparations with differential interference contrast (DIC) and fluorescence microscopy, (ii) tagging of fungal nuclei with fluorescent proteins for the study of nuclear migration, (iii) use of specific inhibitors of major signaling components and generation of corresponding gene deletion mutants via *Agrobacterium tumefaciens*-mediated transformation.

**Conclusions**

Typical CAT formation is frequent between *V. dahliae* germlings, although it is inhibited by the presence of nutrients and varies significantly between different strains. It is also dependent on pH, conidial density, and the history of the fungal cultures used. Cytoplasmic mixing and nuclear migration are permitted through CATs, allowing the formation of heterokaryons when conidia of different genotypes are combined. The formation of CATs in *V. dahliae* requires functional MAP kinase and ROS signaling components, similarly to normal development/morphogenesis and pathogenicity of the fungus.

**CO<sub>2</sub> REPRESSION OF FRUITING BODY FORMATION IN SCHIZOPHYLLUM COMMUNE IS MEDIATED VIA cAMP**

J.F. Pelkmans<sup>1</sup>, S. Westhoff<sup>1</sup>, H.A.B. Wösten<sup>1</sup>, L.G. Lugones<sup>1</sup>

<sup>1</sup>Biology, Microbiology, Utrecht, Netherlands

**Background**

The most important environmental cues impacting fructification in *Schizophyllum commune* are light and CO<sub>2</sub>. Blue light is needed to initiate fructification, while high levels of CO<sub>2</sub> repress this process. The most ubiquitous mechanism of CO<sub>2</sub> sensing in prokaryotes and eukaryotes is based on cellular levels of cAMP. Regulation occurs through synthesis and degradation by adenylate cyclase (AC) and phosphodiesterase (PDE2), respectively. Most ACs localize to membranes and are activated by G proteins. However, there are also soluble ACs that are activated by bicarbonate or calcium ions. It has been proposed that fungal ACs are a hybrid between these two types and in most fungi there is only one gene for this protein.

**Objectives**

To study the mechanism for CO<sub>2</sub> sensing and its effect on fruiting body formation in *S. commune*.

**Methods**

cAMP was added to medium to assess its involvement in CO<sub>2</sub> sensing and fruiting in *S. commune*. Additional copies of *pde2* were introduced by transformation and verified by qPCR. IBMX was used to repress PDE activity.

**Conclusions**

Addition of cAMP to the medium inhibited fructification but did not impact growth. Inhibition of fruiting body formation could be counteracted by overexpressing *pde2*. The *pde2* overexpressor also fructified under repressing CO<sub>2</sub> levels where the wild type strain could not, reinforcing the existence of a link between CO<sub>2</sub> and cAMP levels. Addition of IBMX, an inhibitor of PDE2, to the medium abolished the effect of *pde2* overexpression. Taken together, these results show that CO<sub>2</sub> levels are sensed via cAMP.

**FUNCTIONS OF AUTOPHAGY-RELATED GENE SMATG12 IN FRUITING-BODY DEVELOPMENT OF SORDARIA MACROSPORA**

A. Werner<sup>1</sup>, B. Herzog<sup>1</sup>, S. Frey<sup>1</sup>, S. Pöggeler<sup>1</sup>

<sup>1</sup>Genetics of Eukaryotic Microorganisms, Institute of Microbiology and Genetics, Göttingen, Germany

**Background**

In eukaryotes, autophagy is a highly conserved degradation process by which cytoplasm including organelles is non-selectively engulfed by double-membrane vesicles called autophagosomes. After fusion of the outer membrane with the vacuole/lysosome a vesicle surrounded by the inner membrane, the autophagic body, is degraded by hydrolytic enzymes and building blocks are recycled into the cytoplasm

**Objectives**

In filamentous fungi, autophagy functions as a catabolic mechanism to overcome starvation conditions and to control diverse developmental processes under normal nutritional conditions. We recently showed that in the homothallic ascomycete *Sordaria macrospora*, autophagy related genes encoding components of the conjugation systems are required for fruiting body development or are essential for viability. Here, we cloned and characterized the *S. macrospora* (*Sm*)*atg12* gene, encoding a ubiquitin-fold protein.

**Methods**

To examine the role of *Smatg12* in detail, we replaced it with a hygromycin resistance cassette and generated a homokaryotic  $\Delta$ *Smatg12* deletion strain. GFP-labeled SmATG12 was used to localize the protein *in vivo*.

**Conclusions**

The  $\Delta$ *Smatg12* mutant displayed a decreased vegetative growth rate and was unable to form fruiting bodies. GFP-labeled SmATG12 was detected as punctured structures and co-localized with DsRED-SmATG8 at some places in the cytoplasm. We could show that lipidation of SmATG8 and proper autophagosome formation depends on SmATG12.

**ENZYME ACTIVITY AND MALDI TOF/TOF MS ANALYSIS OF RESPONSES TO STRESS INDUCED BY ARSENIC AND ANTIMONY IN ACIDOMYCES ACIDOPHILUS FROM TIN-MINING SOIL**

W.K. Chan<sup>1</sup>, D. Wildeboer<sup>1</sup>, H. Garelick<sup>1</sup>, D. Purchase<sup>1</sup>

<sup>1</sup>Science and Technology, Middlesex University, London, United Kingdom

**Background**

An *Acidomyces acidophilus* strain has been isolated from a tin mining soil in Cornwall, England that contained approximately 18970 mg kg<sup>-1</sup> arsenic (As) and 228 mg kg<sup>-1</sup> antimony (Sb) with the soil pH around 1. Culture experiments showed that the strain could tolerate up to 22500 mg kg<sup>-1</sup> of As(V) and 100 mg kg<sup>-1</sup> of Sb(V).

**Objectives**

This study examines the protein responses of *A. acidophilus* when exposed to As/Sb using MALDI TOF/TOF.

**Methods**

The strain was exposed for 24 h to 100 mg/L of sodium arsenate (Na<sub>2</sub>HAsO<sub>4</sub>) and potassium antimonate [KSb(OH)<sub>6</sub>]. MALDI TOF/TOF MS analysis was carried out and tentatively identified that the following proteins were up-regulated in response to Na<sub>2</sub>HAsO<sub>4</sub> and KSb(OH)<sub>6</sub>: malate dehydrogenase, phospholipase B, phosphoglycerate kinase, glyceraldehyde-3-phosphate dehydrogenase and 3-isopropylmalate dehydrogenase. In addition, the activities of enzymes glutathione reductase, glutathione transferase, superoxide dismutase and catalase in the presence of As and/or Sb are still being investigated. Also, the isolated *A. acidophilus* and three *A. acidophilus* reference type strains (CBS 335.97, CCF4251 and CCF3679) were characterised by MALDI TOF/TOF and all four strains showed very distinctive spectra that distinguish them readily. It has also been found that *A. acidophilus* grown in different media exhibited different mass spectra, thus affecting the identification of this strain.

**Conclusions**

This provides further and in-depth opportunity to understand the extreme resistance to heavy metals by *A. acidophilus* and also identify the enzymes that are involved in the resistance mechanisms and thus contain biotechnological potential and future scientific uses such as bioremediation and clinical studies.

**THE 7-TRANSMEMBRANE RECEPTOR GPR1 GOVERNS GROWTH, DEVELOPMENT AND MYCOPARASITISM-RELATED FUNCTIONS IN THE FUNGUS TRICHODERMA ATROVIRIDE AND INTERACTS WITH A SUR7 FAMILY MEMBRANE PROTEIN**

S. Zeilinger<sup>1,3</sup>, S. Gruber<sup>1</sup>, T. Radebner<sup>1</sup>, P. Labaf<sup>2</sup>, D.P. Kreil<sup>2</sup>

<sup>1</sup>Biotechnology and Microbiology,

Vienna University of Technology Institute of Chemical Engineering, Vienna, Austria

<sup>2</sup>Chair of Bioinformatics, University of Natural Resources and Life Sciences, Vienna, Austria

<sup>3</sup>Institute of Microbiology, University of Innsbruck, Innsbruck, Austria

**Background**

Species of the fungal genus *Trichoderma* are among the most successful biofungicides in today's agriculture although our understanding of the exact molecular mechanisms of their activity still is fragmentary. The biological control of plant diseases by *Trichoderma* includes direct antagonism of phytopathogenic fungi by parasitism. This mycoparasitic attack comprises sensing of the prey and chemotropic growth towards it followed by activation of "molecular weapons" such as cell wall-lytic enzymes, secondary metabolites, and infection structures. Consequently the receptors and signaling pathways involved in sensing and responding to the prey fungus are of special interest.

**Objectives**

The *Trichoderma atroviride* Gpr1 7-transmembrane receptor has been shown to be essential for regulating mycoparasitism-relevant processes and it is implicated in the recognition of prey-derived signals. For further characterization of Gpr1, respective target genes being regulated by the Gpr1 receptor upon prey recognition have been identified by comparative genome-wide microarray-based transcriptomics of *T. atroviride* wild-type as well as *gpr1* mutants.

**Methods**

Furthermore, direct interactors of Gpr1 were identified by the split-ubiquitin yeast-based two-hybrid system.

**Conclusions**

Functional characterization of one of the identified interactors, a plasma membrane protein belonging to the fungal-specific Sur7 family, by gene deletion revealed a role in the regulation of conidiation, polar growth, and the mycoparasitic attack of the prey fungus.

**Fungal pathogenicity in humans**

## **RAPID DETECTION OF CANDIDA SPECIES, CAUSING OCULAR INFECTION IN PAKISTANI POPULATION**

S. Ali<sup>1</sup>, A. Kanwal<sup>2</sup>

<sup>1</sup>*institute of agriculture sciences, University of the Punjab, Lahore, Pakistan*

<sup>2</sup>*Depart. of Bioinformatics and Biotchnology, Govt. College University Faisalabad, Faisalabad, Pakistan*

### **Background**

The present study was conducted on fungal pathogen (*Candida*) causing ocular infections. The basis for effective treatment is rapid diagnosis of the disease and identification of its causative agent. Due to the limitations of classical methods for the detection of systemic fungal infections, it has become essential to develop a quick, sensitive and specific detection assay.

### **Objectives**

A polymerase chain reaction (PCR) method was to be optimized that would be capable of detecting a wide range of medically important fungi from clinical specimens.

### **Methods**

Eight *Candida species* sequences were downloaded from GenBank or EMBL databases. A set of unique primers were designed based on the conserved region in the given fungal species. To verify the specificity of the designed primers, the BLAST program at the NCBI website was employed to search the primers in short, near exact sequences. These primers were then analyzed by the AmplifX tool.

### **Conclusions**

The results indicated that this study gives the strategy for the rapid detection of *Candida* species on the basis of genotype. A reproducible method for genotypic identification of *Candida species* will be very helpful for the doctors/practitioners to detect the specific species. In current medical facilities in Pakistan, the prediction of *Candida sp.* involved in ocular infection will be a valuable addition of information in the field of medicine. Pharmacists can make different antibiotics against different

diseases related to fungus *Candida* and can easily find out the specific cause of the related disease.

**TRANSCRIPTIONAL PROFILE OF FUSARIUM OXYSPORUM AND FUSARIUM SOLANI CHALLENGED WITH ANTIFUNGAL COMPOUNDS IN VITRO**

A. CASTILLO CASTAÑEDA<sup>1</sup>, J. CASTRO GORDILLO<sup>1</sup>,  
S. RESTREPO RESTREPO<sup>1</sup>, A. CELIS RAMIREZ<sup>1</sup>

<sup>1</sup>BIOLOGICAL SCIENCES, Universidad de los Andes, Bogotá, Colombia

**Background**

*Fusarium* is a genus of filamentous fungi widely distributed and of high importance because several species of the genus are pathogens of plants and humans. In humans *Fusarium* is associated with superficial mycoses as onychomycosis and fungal keratitis in immunocompetent patients. However in immunocompromised patients, the infection can be disseminated and can cause the death of the patient due to the high resistance to antifungal treatments

**Objectives**

This project aimed to analyze the gene expression profile of both *Fusarium oxysporum* and *Fusarium solani* after the exposure to Posaconazole and Amphotericin B

**Methods**

The expression profile was performed by RNA-Seq of *Fusarium* spp and the genes with a significant expression were validated by qRT-PCR. We found an average of 20-30 of differentially expressed genes of the exposed strains relative to the controls

**Conclusions**

Some genes were associated with oxidative stress, ergosterol synthesis and cell wall structure, among others. The role of these genes in resistance against antifungal compounds is discussed. This study contributes to the general knowledge and understanding of the resistance mechanisms of *Fusarium* spp, which could improve the implementation of treatment strategies.

**ANALYSIS OF GENE EXPRESSION PROFILES IN *M. FURFUR* USING NEXT GENERATION**

A. Celis<sup>1</sup>, Y. Amado<sup>2</sup>, D. Urbina<sup>2</sup>, H. De Cock<sup>1</sup>, S. Restrepo<sup>2</sup>

<sup>1</sup>*Biology, Microbiology, Utrecht, Netherlands*

<sup>2</sup>*Biological sciences, LAMFU, Bogotá, Colombia*

**Background**

The *Malassezia* genus is characterized by its lipophilic or lipid dependent species. These traits have been related with virulence, but until now the relation has not been clearly elucidated. *M. furfur* is a species presenting a high level of phenotypic variation. We previously described an atypical isolate of this species, which only assimilates tween 80. This finding suggested host adaptations mechanisms.

**Objectives**

We used microarray analysis to characterize the genetic expression that could give more clues about this metabolic advantage.

**Methods**

We analyzed gene expression differences between *M. furfur* CBS 1878 and the atypical *M. furfur* strain. In those experiments we used Dixon modified agar with and without tween 80. cDNA microarrays were designed and fabricated by Roche Nimblegen (NimbleGen Systems Inc., Madison, WI), using the *Malassezia globosa* genome. Normalization of the intensity values was performed using the VSN method. Differential expression analysis of the profiles was performed using pairwise comparisons and two different methods SAM and Ebayes algorithms. The enriched genes were analyzed by Gene Ontology (GO) terms.

**Conclusions**

The genes over expressed were associated with cyclophilins and thioredoxin, proteins involved in important cellular processes. We validated these results by qPCR. This analysis suggested that these candidate genes could be related with virulence.

**FEMS-1913**

**Fungal pathogenicity in humans**

**ANTIFUNGAL SUSCEPTIBILITY TESTING OF YEASTS ISOLATED FROM THE PATIENTS WITH NOSOCOMIAL INFECTION IN SLOVAKIA.**

V. Hrabovsky<sup>1</sup>, K. Curova<sup>1</sup>, L. Siegfried<sup>1</sup>

<sup>1</sup>*Pavol Jozef Šafárik University in Košice Faculty of Medicine,  
Department of Medical and Clinical Microbiology, Kosice, Slovakia*

**Background**

Yeasts are common fungal opportunistic pathogens in humans playing a significant role in the morbidity and mortality of immunocompromised patients.

**Objectives**

The aim of the study was antifungal susceptibility testing of yeasts isolates to fluconazole, voriconazole, caspofungin, and anidulafungin.

**Methods**

From January 2013 through October 2014, 3200 isolates were obtained from hospitalized patients with nosocomial yeast infection. The distribution of the species obtained was *Candida albicans* (75.4%), *C. glabrata* (8.2%), *C. tropicalis* (4.8%), *C. kefyr* (3.4%), *C. parapsilosis* (2.5%), *C. lusitanae* (1.9%), *C. famata* (1.4%), *C. krusei* (1.4%), *C. guilliermondii* (1%), *C. sake* (1%), *T. asahii* (1%) and *T. mucoides* (1%). MICs of antifungal agents were determined by Etest method.

**Conclusions**

All the isolates of *C. albicans* were susceptible to the fluconazole. Higher voriconazole MICs were observed in isolates exhibiting higher fluconazole MICs, frequently in *C. krusei* and *C. glabrata*. Isolates with echinocandins MICs suggesting reduced susceptibility were only sporadic cases.

**Fungal pathogenicity in humans**

**VICISSITUDES IN ADHESION TO DENTURE ACRYLIC SURFACES OF ORAL CANDIDA DUBLINIENSIS ISOLATES FOLLOWING BRIEF EXPOSURE TO SUB-CIDAL CONCENTRATIONS OF POLYENES, ECHINOCANDINS, AZOLES AND CHLORHEXIDINE GLUCONATE**

A. Ellepola<sup>1</sup>, B. Joseph<sup>1</sup>, Y. Al-Tarakemah<sup>1</sup>, L. Samaranayake<sup>2</sup>, Z. Khan<sup>3</sup>

<sup>1</sup>Faculty of Dentistry, Kuwait University, Safat, Kuwait

<sup>2</sup>School of Dentistry, University of Queensland, Brisbane, Australia

<sup>3</sup>Faculty of Medicine, Kuwait University, Safat, Kuwait

**Background**

Adherence of *Candida* to denture acrylic surfaces is implicated as the initial process in the pathogenesis of *Candida*-associated denture stomatitis. This condition can be treated with antimycotic agents belonging to polyene, echinocandin and azole groups of antimycotics. In addition chlorhexidine is also used in its management. In the niches of the mouth the intraoral concentration of these drugs fluctuates considerably due to the dynamics of the oral environment and *Candida* may undergo only to a brief exposure to therapeutic agents. It has been suggested that *Candida dubliniensis* may play an important role in the establishment and persistence of *C. dubliniensis* induced-denture stomatitis.

**Objectives**

Hence, the effect of brief exposure to sub-lethal concentrations of nystatin, amphotericin B, caspofungin, ketoconazole, fluconazole and chlorhexidine gluconate on adhesion of these isolates to denture acrylic surfaces was investigated.

**Methods**

After determining the minimum inhibitory concentration of the drugs, twenty oral isolates of *C. dubliniensis* were exposed to sub-lethal concentrations of these six drugs for one hour. Subsequently, the drugs were removed by dilution and the adhesion of these isolates to denture acrylic strips was assessed by an *in vitro* adhesion assay.

**Conclusions**

Compared to controls, exposure to nystatin, amphotericin B, caspofungin, ketoconazole, fluconazole and chlorhexidine gluconate suppressed the ability of *C. dubliniensis* isolates to adhere to denture acrylic surfaces by 74.68%, 74.27%, 73.33%, 57.31%, 44.57% and 56.53% ( $P < 0.001$  for all drugs), respectively. Hence, brief exposure to sub-lethal concentrations of antimycotics seems to exert an antifungal effect by suppressing the adhesion to denture acrylic surfaces of *C. dubliniensis* oral isolates.

**IDENTIFICATION OF EXTRACELLULAR ASPERGILLUS SPP COMPONENTS THAT INTERACT WITH IMMUNE RECEPTORS.**

N. Escobar<sup>1</sup>, S. Braem<sup>2</sup>, P. Punt<sup>3</sup>, A. Ram<sup>3</sup>, J. Van Strijp<sup>2</sup>, P.J. Haas<sup>2</sup>, H. Wosten<sup>1</sup>, H. de Cock<sup>1</sup>

<sup>1</sup>Microbiology, University of Utrecht, Utrecht, Netherlands

<sup>2</sup>Microbiology, UMCU, Utrecht, Netherlands

<sup>3</sup>Institute of Biology, Leiden University, Leiden, Netherlands

**Background**

*Aspergillus* species are worldwide distributed and ubiquitous in the environment, among this genus relevant industrial and medical relevant species are present. For instance, *A. niger* is used in industrial production systems and has also been reported to cause infections. Extracellular compounds from *Aspergillus* spp can play various roles during human infections, for example by modulation of immune system response.

**Objectives**

Identify novel extracellular fungal components that interact with immune receptors.

**Methods**

Culture supernatants from various *A. niger* strains (WT and mutants strains) were screened via a *Tricolor Assay* enabling identification of components that interact with cellular immune receptors. Briefly, the culture supernatant was first co-incubated with a human immune cell mix (neutrophils, monocytes and lymphocytes). Subsequently, fluorescently labeled immune receptor antibodies were incubated with the pre-incubated supernatant-cells mix in a 96-well plate. Subsequently, the plate was centrifuged, washed and cells were fixed. Finally, antibody-antigen interactions were measured using FACS analysis

**Conclusions**

We did not detect extracellular components in supernatants of *A. niger* wt (N402) that interact with immune receptor. However, a derivative of this *A. niger* wt strain, the mutant D15#26, did produce such components and which appear to be small since a 3 kDa filtrated supernatant was still active. This *A. niger* mutant strain lacks extracellular proteases due to a PrtT mutation. However, it also contains additional undefined mutations due to UV mutagenesis and which for example prevents acidification of the medium. We are characterizing this mutant to identify the components and genes that are involved.

#### **B39 - INVESTIGATION OF DERMATOLOGICAL SPECIMENS FOR SUPERFICIAL MYCOSES**

I. Ezeajugh<sup>1</sup>, A. Lual<sup>1</sup>, R. Siddiqui<sup>1</sup>, C. Harris<sup>1</sup>

<sup>1</sup>*Standards Unit, Public Health England, London, United Kingdom*

#### **Background**

The term ‘superficial mycoses’ refers to fungal infections usually confined to the outer layers of the skin, hair and nails. Superficial fungal infections are chronic and recurring conditions and are caused by dermatophytes as well as non-dermatophytes.

Infection by dermatophytes is cutaneous and generally restricted to the non-living cornified layers in patients who are immunocompetent. They are generally unable to penetrate tissues which are not fully keratinised. Reactions to infections can range from mild to severe depending upon the host’s immune response, the virulence of the infecting species, the site of infection and environmental factors. The dermatophytes are classified in three genera: *Epidermophyton*, *Microsporum* and *Trichophyton* species.

There are non-dermatophytes that can infect healthy skin, nails damaged by physical trauma, or pre-existing infection with a dermatophyte.

#### **Objectives**

Aimed at practising professionals in the field of microbiology, B39 is a diagnostic tool which describes and recommends the procedures that can be used to visualise and isolate dermatophytes, non-dermatophytes and other fungi from skin, nail and hair specimens.

B39 is developed by professionals in the field with specialist input and is intended as a general resource for laboratory staff, clinicians and healthcare commissioners. This document focuses on how detection and accurate identification can aid the management and control of superficial mycoses.

#### **Methods**

-

#### **Conclusions**

B39 provides guidance on the best minimum practice when investigating infection caused by dermatophytes, non-dermatophytes and other fungi. It provides information on rapid molecular methods and culture testing for these fungi and aims to help drive pathology modernisation by recommending new technologies.

**Fungal pathogenicity in humans**

**ANTIFUNGAL ACTIVITY AND REDUCTION OF ERGOSTEROL CONTENT OF TRICHOPHYTON RUBRUM CAUSED BY GLYCOALKALOID ALFA-SOLANINE**

A. Fachin<sup>1</sup>, F. Barbosa<sup>1</sup>, T. Bitencourt<sup>1</sup>, M. Marins<sup>1</sup>

<sup>1</sup>Unidade de Biotecnologia, Unaerp, Ribeirão Preto São Paulo, Brazil

**Background**

The dermatophyte *Trichophyton rubrum* is the most common causative agent of dermatophytosis in the world. Due the prominence of dermatophytosis and its socio-economic consequences, there is a need to develop of new antifungal agents. Most of the currently available drugs presents side effects and are ineffective against resistant strains of fungi. The plants are a significant source of biologically active natural products and many chemical structures are models for the synthesis of new drugs. The  $\alpha$ -solanine is a glycoalkaloid extracted from potato sprouts (Solanaceae) and has several biological activities, including antimicrobial activity.

**Objectives**

The aim of this study was to determine the minimum inhibitory concentration (MIC) of  $\alpha$  solanine and to quantify the ergosterol content of *T.rubrum* exposed to natural compound  $\alpha$ -solanine.

**Methods**

The susceptibility assay was performed using the microdilution test of  $\alpha$ -solanine and control fluconazole in the range of to 1000-1.9 $\mu$ g/mL toward the strain ATCC MYA-3108 of *T. rubrum*. Ergosterol content was extracted from mycelia exposed for 48 hours to MIC concentration of antifungals and was quantified by spectrophotometry.

**Conclusions**

The  $\alpha$ -solanine compound showed a MIC of 3.12  $\mu$ g /mL and fluconazole showed a MIC of 63  $\mu$ g/mL toward the strain ATCC MYA-3108. The  $\alpha$ - Solanine and fluconazole reduced 35% and 40.95% of ergosterol content, respectively. The  $\alpha$ -solanine showed significant activity toward *T.rubrum* and reduced the level of ergosterol of cell membrane, which is a specific target of the fungal cell.

**MOLECULAR IDENTIFICATION OF CANDIDA SPECIES ISOLATED FROM PATIENTS WITH VULVOVAGINAL CANDIDIASIS IN IRAN**

H. fakhim<sup>1</sup>, H. badali<sup>1</sup>

<sup>1</sup>medical mycology, Mazandaran University of Medical Sciences, Sari, Iran

**Background**

Candidal vulvovaginitis is an infection of the vagina's mucous membranes by *Candida* species. Up to 75% of women will have this infection at some point in their lives, and approximately 5% will have recurring episodes. It is the second most common cause of vaginal inflammation after bacterial vaginosis and usually caused by *C. albicans* but other species, including *C. glabrata*, *C. tropicalis*, *C. krusei* and *C. africana*.

**Objectives**

The aim of the present study was to molecular identification of *Candida* species isolated from patients with vulvovaginal candidiasis.

**Methods**

A total of 150 patients refer to Mazandaran University of Medical Sciences from 2013-2014. The vaginal swab specimens were cultured on Sabouraud Dextrose Agar (SDA) and identified based on conventional methods (Germ Tube Test, Chlamydospore production) and subsequently confirmed by PCR-HWP1 (produces 3 different DNA fragments: approximately 780 bp for *C. africana*, 941 bp for *C. albicans* and 250 bp for *C. glabrata*).

**Conclusions**

The current study shows that *C. albicans* as predominant species isolated from vulvovaginitis. It can be concluded that molecular diagnostic methods are reliable and would be useful for identification of medically important *Candida* species in clinical samples. Therefore considerable attention has been paid to prevention and treatment of microbial growth, which has resulted in improvement of patient management. Although recently molecular approaches have been developed for the identification and discrimination of *Candida* species, novel techniques for the diagnosis based on species level have been established in routine laboratories.

<sup>4</sup>Department of Social Medicine, Alborz University of Medical Sciences, KARAJ, Iran

<sup>5</sup>School of Nursing and Midwifery, Alborz University of Medical Sciences, KARAJ, Iran

### **Background**

*Candida albicans* is a frequent component of oral ecology found in up to 75% of humans; particularly among immunocompromised patients. *Candida* species can cause a multitude of disease ranging from mild oral disease to disseminated candidiasis.

### **Objectives**

In this study, an attempt has been made to determine susceptibility pattern of four antifungal agents against the *Candida* species isolated from cancer patients with oropharyngeal candidiasis.

### **Methods**

Isolation and identification of *Candida* spp was done based on standard procedures. Antifungal resistance pattern was carried out according to CLSI guideline. Identification of *Candida* species were confirm using the 18s Ribosomal RNA.

### **Conclusions**

Leukemia and lymphoma were the most frequent cancer in the studied group, accounting for 17 (34%) and 12 (24%) respectively. A total of 29 *Candida* spp were isolated from 29 of cancer patients; of which 17 were *C. albicans* and 12 were *C. non – albicans*. All the *Candida* spp were confirmed using the 18s Ribosomal RNA. Among all the *Candida* spp, *Candida non – albicans* showed a high resistance pattern to amphotericin B (MIC 07 µg / ml) and ketokenazole (MIC=05 µg / ml). In conclusion, oropharyngeal Candidiasis is a serious infection among cancer patients. The isolated *candida* spp were resistant to common antifungal agents which may leads to longer hospital stay, more expensive/ toxic drugs and higher mortality. Therefore, interval surveillance is necessary in developing institutional guidelines.

**Fungal pathogenicity in humans**

**XANTHOMEGNIN DETECTION DOES NOT DISCRIMINATE BETWEEN TRICHOPHYTON RUBRUM AND T. MENTAGROPHYTES COMPLEXES**

A. KANDEMİR<sup>1</sup>, M. ILKIT<sup>1</sup>, A. CURUK<sup>2</sup>

<sup>1</sup>Medical Microbiology, Cukurova University School of Medicine, Adana, Turkey

<sup>2</sup>Medical Biochemistry, Cukurova University School of Medicine, Adana, Turkey

**Background**

High-performance liquid chromatography (HPLC) is a reliable and robust methodology in medical diagnostics, including the detection of hemoglobin variants, vitamin D levels, and *Trichophyton rubrum* in skin and nail materials. Previous information reported that the latter was reliably identified using xanthomegnin activity via HPLC.

**Objectives**

In the present study, we aimed to discriminate between the two most common human pathogenic dermatophytic fungi, *T. rubrum* and *T. mentagrophytes* complexes, via the detection of xanthomegnin using HPLC methodology.

**Methods**

Hence, we investigated 32 reference dermatophyte strains: *Arthroderma* spp. ( $n=7$ ), *T. rubrum* ( $n=18$ ), and *T. mentagrophytes* complex ( $n=7$ ) strains. In addition, we analyzed both clinical samples and strains from 13 samples identified as *T. rubrum* ( $n=9$ ) and *T. interdigitale* ( $n=4$ ) using ITS-sequencing. Twelve of 18 reference *T. rubrum* complex strains produced detectable amounts of xanthomegnin. Moreover, and more importantly, 2 *A. vanbreuseghemii* and 1 *T. interdigitale* reference strains also demonstrated xanthomegnin activity. Furthermore, from a total of 13 clinical samples, 11 clinical samples and 11 clinical strains were positive for xanthomegnin, including *T. interdigitale* strains.

**Conclusions**

Although xanthomegnin detection is a rapid and inexpensive method, we concluded that it is not a reliable method for discriminating between *T. rubrum* and *T. mentagrophytes* complexes given that only two-thirds of the reference *T. rubrum* complex strains and 3 strains from the *T. mentagrophytes* complex produced xanthomegnin activity. In addition, we believe that the results of the present study should be of interest to scientists and clinicians specifically in the field of medical mycology.

**Fungal pathogenicity in humans**

**INTERACTIONS BETWEEN HUMAN EXTRACELLULAR MATRIX PROTEINS AND CANDIDA GLABRATA CELL WALL, STUDIED BY CHEMICAL CROSSLINKING AND MASS SPECTROMETRY**

J. Karkowska-Kuleta<sup>1</sup>, D. Zajac<sup>1</sup>, O. Bochenska<sup>1</sup>, A. Kozik<sup>1</sup>

<sup>1</sup>Department of Analytical Biochemistry,  
Jagiellonian University Faculty of Biochemistry Biophysics and Biotechnology,  
Krakow, Poland

**Background**

*Candida glabrata* causes almost 20% of all fungal infections in humans. This yeast is distantly related to other medically important *Candida* species (such as the most widespread fungal pathogen *C. albicans*) and significantly differs from those species in the pathogenicity profile. One of essential steps in the microbial colonisation of human organism is the adherence of pathogen to host cells and the supporting extracellular matrix (ECM).

**Objectives**

*C. glabrata* cell surface is involved in initiating the contact between fungus and host during infection. The current study aims at identifying the major cell wall components that interact with human ECM proteins.

**Methods**

*C. glabrata* cell wall-associated proteins were isolated with  $\beta$ -1,3- or  $\beta$ -1,6-glucanases and allowed to interact with biotin-labelled fibronectin, vitronectin and laminin. The formed protein-protein complexes were fixed by chemical crosslinking with a heterobifunctional, photoactivatable reagent, sulfosuccinimidyl 2-[(4,4'-azipentanamido)ethyl]-1,3'-dithiopropionate. The stably coupled proteins were adsorbed on streptavidin-conjugated beads and identified by tandem mass spectrometry.

**Conclusions**

Binding of fibronectin, vitronectin and laminin to *C. glabrata* cell surface was confirmed and several fungal proteins involved in these interactions were identified. Some of them are common binders for all three investigated ECM proteins and predominantly belong to a group of loosely bound with the cell surface, cytoplasm-derived proteins. Examples of these ECM-binding proteins include enolase, alcohol dehydrogenase, glyceraldehyde-3-phosphate dehydrogenase, 6-phosphogluconate dehydrogenase and malate synthase.

This work was supported by the Jagiellonian University in Krakow (Statutory Funds of the Faculty of Biochemistry, Biophysics and Biotechnology No.BMN13/2014, K/DSC/002510/ awarded to JKK).

**USE OF PCR-RFLP AND PCR-HWP1 FOR IDENTIFICATION OF CANDIDA SPECIES ISOLATED FROM CYSTIC FIBROSIS PATIENTS.**

S. Khodaveisi<sup>1</sup>, H. Badali<sup>2</sup>, P. Solimani<sup>3</sup>

<sup>1</sup>Department of Medical Mycology and Parasitology,  
Tehran University of Medical Sciences, Tehran, Iran

<sup>2</sup>Department of Medical Mycology and Parasitology,  
Mazandaran University of Medical Sciences, Sari, Iran

<sup>3</sup>Department of Medical Mycology and Parasitology,  
Kerman University of Medical Sciences, Kerman, Iran

**Background**

Due to the predisposing conditions in patients with cystic fibrosis (CF) caused by defective mucociliary clearance facilitates of colonization and invasion with *Candida* species has dramatically increased. Molecular techniques utilizing amplification of target DNA provide quick and precise methods for diagnosis and identification of *Candida* species.

**Objectives**

The aim of current study was identification of the most medically common isolated *Candida* species from the air way of CF patients by PCR-RFLP and amplification of HWP1 gene.

**Methods**

A total of 42 CF patients presenting symptoms referred to pediatric respiratory diseases research center were screened for the presence of *Candida* spp. The isolates initially were phenotypically identified and confirmed by molecular approaches based on restriction fragment length polymorphism (PCR-RFLP) for discrimination of *C. albicans* of non *albicans* and amplification of HWP1 gene for discrimination of *C. albicans* from *C. dubliniensis* and *C. africana* was conducted.

**Conclusions**

Results show that *C. albicans* was the most frequently isolated species (83.8%) followed by non-*albicans* included *C. parapsilosis* (7.1%), *C. glabrata* (3.2%), and *C. tropicalis* (3.2%). The restriction patterns of each *Candida* species were perfectly specific. Since *MspI* is not able to discriminate between three morphological similar species, *C. albicans*, *C. dubliniensis* and *C. africana*, we used PCR amplification of *hwp1* gene, which (7.1%) species from *C. albicans* identified as *C. dubliniensis*, however *C. africana* strains were not found. It can be concluded that molecular diagnostic methods are reliable and would be useful for identification of medically important *Candida* species in clinical samples.

<sup>6</sup>Department of Microbiology,

Aravind Eye Hospital and Postgraduate Institute of Ophthalmology, Coimbatore, India

#### Background

Fungal keratitis is a serious suppurative, usually ulcerative corneal infection which may result in blindness or reduced vision.

#### Objectives

Our aim was to study the spectrum of fungi causing keratitis in South India based on the data collected at the Aravind Eye Hospital and Postgraduate Institute of Ophthalmology, Coimbatore, Tamilnadu between 2005 and 2014.

#### Methods

Fungal strains were isolated from corneal scrapings of keratitis patients. Morphological examination of the isolates and nucleotide sequence-based identification were performed.

#### Conclusions

The most frequently occurring genus was *Fusarium*. Representatives of five *Fusarium* species complexes were detected. Members of *Fusarium solani* species complex (FSSC) were the most frequent, followed by the species complexes *Fusarium dimerum* (FDSC), *Fusarium fujikuroi* (FFSC), *Fusarium oxysporum* (FOSC) and *Fusarium incarnatum-equiseti* (FIESC). *Fusarium napiforme* from FFSC and the sexual fungus *Neocosmospora vasinfecta* from FOSC were firstly detected from keratitis. *Aspergillus* proved to be the second most frequent genus with *Aspergillus*

*flavus* as the predominant species, followed by *Aspergillus fumigatus* and *Aspergillus terreus*. *Aspergillus tamarai*, *Aspergillus nomius* and *Aspergillus pseudotamarai* from section *Flavi*, *Aspergillus tubingensis*, *Aspergillus brasiliensis*, *Aspergillus neoniger* and *Aspergillus welwitschiae* from section *Nigri*, *Aspergillus sydowii* and *Aspergillus variegator* from section *Nidulantes*, *Aspergillus amstelodami* from section *Aspergillus*, *Aspergillus melleus* from section *Circumdati* and *Aspergillus lentulus* from section *Fumigati* of the genus were firstly recognized as potential causal agents of fungal keratitis.

This work was supported within the frames of the Indo-Hungarian bilateral exchange program (Ref. IA/INSA-HAS Project/2007 & 2010). Csaba Vágvölgyi thanks the visiting professor program, Deanship of Scientific Research, King Saud University, Riyadh.

**Fungal pathogenicity in humans**

**FUGEMIA IN HOSPITALIZED PATIENTS WITH PROLONGED FEVER WITH BACTEC METHOD**

*R. Razzaghi<sup>1</sup>, M. Momen-Heravi<sup>1</sup>, M. Erami<sup>1</sup>*

*<sup>1</sup>infectious disease, Kashan University of Medical Sciences, Kashan, Iran*

**Background**

fungemia is a very important infection in terms of incidence and mortality. It can be caused by several species of the genus *Candida* and should be diagnosed and treated quickly

**Objectives**

This study was performed to assess prevalence of fungemia in patients with prolonged fever using two blood culture method

**Methods**

This descriptive study was carried on 330 blood samples obtained from patients with prolonged fever despite widespread antibiotic in Beheshti hospital of Kashan using both BHI and BACTEC blood culture within 2010-2013

**Conclusions**

Among 330 patients with prolonged fever, 16 cases of fungemia were detected which all of them were positive in BACTEC method and 12 were positive in BHI method. All of the isolated fungus were *Candida* and the most frequent agent of candidemia was *Candida Albicans*. The predisposing underlying factors were malignancy, diabetes, using of widespread antibiotics and corticosteroid, trauma and surgery. The rate of fungemia was 4.8% (16/330). We found *Candida Albicans* as the most common causative agent of candidemia in our samples.

**Fungal pathogenicity in humans**

### **CASE SERIES OF RHINOCEREBRAL MUCORMYCOSIS**

M. Momen-Heravi<sup>1</sup>, R. Razzaghi<sup>1</sup>, H. Afzali<sup>1</sup>, M. Erami<sup>1</sup>

<sup>1</sup>*infectious disease, Kashan University of Medical Sciences, Kashan, Iran*

#### **Background**

Rhinocerebral mucormycosis (RCM) is a rare, fulminating opportunistic fungal infection caused by a fungus of order Mucorales

#### **Objectives**

The purpose of this paper is to draw attention to the clinical presentation of RCM and to emphasize need for high index of suspicion in diagnosis and treatment

#### **Methods**

This was a case series study conducted in Beheshti Hospital of Kashan, from 2001 to 2013. The charts of identified patients were reviewed for the following information: demographics, predisposing conditions, anatomical location of infection, treatment, length of hospital stay

#### **Conclusions**

Cases were between 21 to 88 year old. The most patient were female (sex ratio: 2). The clinical sign and symptoms of patients were hematemesis, epistaxis, melena, headache, pain, swelling and tenderness on the face and paranasal sinuses, malaise and weakness, fever, blurred vision, periorbital edema, black secretion and necrosis of nasal septum or hard palate, cranial nerve palsy. All the patients had history of diabetes. CT scan of PNS revealed consolidation, increased thickness, necrosis and disruption of mucosal wall of sinuses. Amphotericin B was prescribed for all the patients. The length of hospital stay was more than 20 days. Blindness occurred in one patient. 3 patients died and the rest recovered

The diagnosis of rhinocerebral mucormycosis should be considered in the clinical setting of necrotic sinusitis in diabetic patients. Early diagnosis and treatment are crucial factors leading to a good outcome.

**Fungal pathogenicity in humans**

**BGL2P FROM SACCHAROMYCES CEREVISIAE CELL WALL – THE HOMOLOG OF CANDIDIASIS BIOMARKER FROM CANDIDA ALBICANS IS ABLE TO FORM FIBRILS**

V. Rekstina<sup>1</sup>, T. Kalebina<sup>1</sup>

<sup>1</sup>Faculty of Biology, Lomonosov Moscow State University, Moscow, Russia

**Background**

The most common fungal infections in humans are candidiasis caused by *Candida* yeast. A major, highly conserved yeast cell wall (CW) protein Bgl2p, which can also be secreted into the growth medium, plays a significant role in candidiasis. It was shown that the injected into a mouse's bloodstream *C.albicans* with *BGL2* deletion possessed decreased infectivity compared to the one without *BGL2* deletion (Sarthý et al., 1997). On the other hand, high level of antibodies against Bgl2p is prognostic factor, which defines the risk of mortality (Pitarch et al., 2006). Authors proposed to use Bgl2p from *C.albicans* for vaccine development. Earlier we demonstrated that Bgl2p from *S.cerevisiae* CW (Bgl2p homolog from *C.albicans*) could reveal amyloid properties (Kalebina et al., 2008). At the beginning of our work the process of Bgl2p amyloid formation remained unclear.

**Objectives**

It was suggested that Bgl2p as well as many other proteins of microorganisms appeared as a virulence factor due to its amyloid forming ability. In order to verify it we needed to study whether Bgl2p was able to form fibrils under conditions similar to those of a bloodstream. Primarily we were interested in investigating the influence of two factors on Bgl2p fibrillation: the pH value within a neutral range and the presence of regulatory molecules such as polyphosphates.

**Methods**

We investigated Bgl2p from non-pathogenic *S.cerevisiae* as a model using fluorescence confocal and electron microscopy, fluorescence spectroscopy, bioinformatics analysis.

**Conclusions**

Bgl2p fibril formation ability was strongly regulated by pH value (Bezsonov et al., 2013), polyphosphates, divalent cations and buffer components. The results obtained allowed us to conclude that Bgl2p might exist in fibrillary form under bloodstream-like conditions. The described Bgl2p amyloid formation ability is important for further fighting the candidiasis including vaccine development, using Bgl2p from non-pathogenic *S.cerevisiae*.

<sup>6</sup>Laboratório de Micologia Clínica, Universidade Estadual Júlio de Mesquita Melo, Araraquara, Brazil

### Background

*Paracoccidioides* spp, a complex of several phylogenetic species, is the agent of paracoccidioidomycosis (PCM). PCM is endemic in Latin America, with 80% of cases reported in Brazil, where it is the eighth-leading cause of mortality among infectious and parasitic diseases, establishing it as a serious public health problem. The use of small molecules of natural origin as medicines or as prototypes of drugs is a well established theme in the drugs development.

### Objectives

Argentilactone, bioactive metabolite isolated from *Hyptis ovalifolia* and inhibited the isocitrate lyase from *Paracoccidioides*. Thiosemicarbazide is a small molecule terpene camphene derivative that inhibits the growth of *Trichophyton mentagrophytes*. Indole alkaloids due their already described antifungal activity, we have included several carboline alkaloids isolated from *Rubiaceae* species in our screening antifungal program aiming to discover compounds with potential to inhibit malate synthase from *Paracoccidioides*.

### Methods

In this study we performed the transcriptome, proteome analysis and virtual screening of *Paracoccidioides* spp. yeast cells growth in the presence of compounds and/or itraconazole and amphotericin B.

### Conclusions

A total of 1.058 genes were identified, of which 208 were up-regulated and 850 down-regulated in argentilactone response. Four indol alkaloids showed ability to reduce the *PbMLSr* activity and inhibit the adhesion of the fungus and *PbMLS* to extracellular matrix components. In our proteomic analyzes various classes of proteases were suppressed in the presence of thiosemicarbazide, were identified and sequenced 11

differentially expressed proteins in the condition with itraconazole, and 29 for the condition treated with amphotericin B.

**Fungal pathogenicity in humans**

## **ORAL MICROFLORA AND THEIR RELATION TO RISK FACTORS IN HIV+ PATIENTS WITH OROPHARYNGEAL CANDIDIASIS**

H. Shokri<sup>1</sup>

<sup>1</sup>*Mycology Research Center,*

*Faculty of Veterinary Medicine Amol University of Special Modern Technologies, Amol, Iran*

### **Background**

Oropharyngeal candidiasis (OPC) is considered an opportunistic infection caused by a ubiquitous fungal organism that is routinely seen as normal oral flora.

### **Objectives**

The purpose of this study was to determine the prevalence of oral microflora and association of oral candidiasis and multiple risk factors in HIV<sup>+</sup> patients.

### **Methods**

The present study included 100 HIV-infected patients participated in Imam Khomeini Hospital, Tehran, Iran for OPC and HIV. Samples were obtained from the oral cavity and direct microscopic examination, gram staining and culture on standard microbiological media were performed in all patients. CD<sub>4</sub><sup>+</sup> cell count/CD<sub>4</sub><sup>+</sup> percentage were also calculated.

### **Conclusions**

A total of 460 bacterial colonies were obtained and *Streptococcus mutans* (15.4%) was the most frequently isolated species in the HIV<sup>+</sup> patients. In addition, 254 yeasts (from 4 different genera) were isolated from the patient under study. *Candida* species (94.4%) were the most frequently obtained genera, followed by *Saccharomyces* (2.4%), *Kluyveromyces* and *Cryptococcus* (1.6% for both) species. *Candida albicans* (37.2%) was the most common species isolated from HIV<sup>+</sup> patients with OPC. The mean CD<sub>4</sub><sup>+</sup> cell counts were 154.5 cells/μL, with a range of 8 to 611 cells/μL. Thirty percent (30%) patients had a CD<sub>4</sub><sup>+</sup> cell count between 101 and 200 cells/μL (28.7% of total yeasts isolated). Our results showed that yeasts of the genus *Candida* were isolated at a comparable rate from the oral cavity of HIV<sup>+</sup> patients and there was no significant difference of the variables CD<sub>4</sub><sup>+</sup> cell count and yeast counts.

**FEMS-0586**

**Fungal pathogenicity in humans**

**DIFFERENTIAL EXPRESSION OF THE VACUOLAR ASPARTIC PROTEINASE (APR1) GENE IN CANDIDA ALBICANS STRAINS ISOLATED FROM MALAYSIAN AND IRANIAN HUMAN AND MICE BLOOD**

H. Shokri<sup>1</sup>

<sup>1</sup>*Mycology Research Center,*

*Faculty of Veterinary Medicine Amol University of Special Modern Technologies, Amol, Iran*

**Background**

Intracellular proteinase A is an aspartic enzyme in *Candida albicans* that is expressed by *APR1* gene.

**Objectives**

The aims of this study were to evaluate and to compare *APR1* gene expression in *C. albicans* strains isolated from Malaysian and Iranian patients and mice infected by *C. albicans* obtained from Malaysian and Iranian patients.

**Methods**

The evaluation of *APR1* gene expression was performed using reverse transcriptase-polymerase chain reaction (RT-PCR) with two-pair primers and 18S rRNA as housekeeping gene. The expression of *APR1* gene and 18S rRNA was determined on agarose gel electrophoresis.

**Conclusions**

The results did not show any significant difference in *APR1* gene expression between *C. albicans* isolated from mice blood infected by *C. albicans* isolated from Malaysian and Iranian patients ( $p>0.05$ ). The expression of *APR1* gene in *C. albicans* strains isolated from Malaysian patients was more than Iranian patients ( $p<0.05$ ). In addition, the gene expression in *C. albicans* strains obtained from mice blood was significantly higher than *C. albicans* strains isolated from both Malaysian and Iranian patients ( $p<0.05$ ). Considering to the important role of intracellular proteinase A in *C. albicans*, *APR1* gene as producer of this enzyme can act as an important gene in virulence of *C. albicans* in different environmental situations.

**Fungal pathogenicity in humans**

**ANTIFUNGAL ACTIVITY OF ZATARIA MULTIFLORA, PLARGONIUM GRAVEOLENS AND CUMINUM CYMINUM ESSENTIAL OILS TOWARDS THREE SPECIES OF MALASSEZIA ISOLATED FROM PATIENTS WITH PITYRIASIS VERSICOLOR**

H. Shokri<sup>1</sup>

<sup>1</sup>*Mycology Research Center,*

*Faculty of Veterinary Medicine Amol University of Special Modern Technologies, Amol, Iran*

**Background**

*Malassezia* species have been recognized as members of the microbiological flora of human skin that cause skin diseases such as pityriasis versicolor (PV).

**Objectives**

To investigate the anti-*Malassezia* activities of *Zataria multiflora*, *Plargonium graveolens* and *Cuminum cyminum* essential oils (EOs) against different pathogenic *Malassezia* species isolated from patients with pityriasis versicolor (PV).

**Methods**

The EOs were obtained by water-distillation using a Clevenger-type system. Anti-*Malassezia* activity against *Malassezia* species was carried out using disk diffusion method in Dixon agar.

**Conclusions**

The main oil components were carvacrol (61.3%) and thymol (25.2%) for *Z. multiflora*,  $\alpha$ -pinene (30%) and limonene (21%) for *C. cyminum* and citronelol (28.2%) and geraniol (22.1%) for *P. graveolens*. The three *Malassezia* species showed a similar susceptibility to the three plants tested, *C. cyminum* (mean value: 48.3 mm) being the most active, followed by *Z. multiflora* (mean value: 28.1 mm) and *P. graveolens* (mean value: 26.1 mm). This study indicated that *Z. multiflora*, *P. graveolens* and *C. cyminum* EOs have considerable anti-*Malassezia* activities, deserving further investigation for clinical applications for the treatment of PV.

**FEMS-1192**

**Fungal pathogenicity in humans**

**DELETION LIBRARY REVEALS POTENTIAL GENES INVOLVED IN THE VIRULENCE OF CANDIDA PARAPSILOSIS**

R. Toth<sup>1</sup>, V. Cabra<sup>2</sup>, J.D. Nosanchuk<sup>2</sup>, C. Vagvolgyi<sup>1</sup>, A. Gacser<sup>1</sup>

<sup>1</sup>Department of Microbiology, University of Szeged, Szeged, Hungary

<sup>2</sup>Department of Microbiology and Immunology, Albert Einstein College of Medicine, New York, USA

**Background**

Since the 1980s, fungi have emerged as causes of human disease. Some fungal species are opportunistic pathogens, that are only able to cause diseases in individuals with damaged physical barriers or/and altered immune status. The incidence of *C. parapsilosis* caused candidemia has dramatically increased over the past decade, therefore, the understanding of the pathomechanism of this species becomes urgent.

**Objectives**

Despite the growth of genome sequence information, a large number of fungal genes remain uncharacterized. In our previous work several fungal transcriptional factors have been identified using RNA-Seq data that were over expressed during host-pathogen interactions. Based on these data we aimed to generate a knock out library to be able to analyze these genes individually.

**Methods**

Fusion PCR was applied to generate gene specific deletion constructions to disrupt genes from the genome of a *C. parapsilosis* double auxotrophic strain. The growth abilities of the null mutant strains were tested in different conditions such as different medias and temperatures along with survival in the presence of various stressors.

**Conclusions**

We have found null mutants that show differences in appearance such as increased pseudohyphae formation, regressed growth on different temperatures and alkali-phobic phenotype. Comparison of the virulence of these deletion strains using infectious models is now in progress. In the future with the use of this method we are able to identify key regulatory factors that may play a role in the virulence of *C. parapsilosis* during host-pathogen interactions.

### **Fungal pathogenicity in humans**

#### **THE CFEM HEME-IRON ACQUISITION NETWORK IN PATHOGENIC FUNGI**

Z. weissman<sup>1</sup>, D. kornitzer<sup>1</sup>, L. nasser<sup>2</sup>, H. dvir<sup>2</sup>

<sup>1</sup>*mol. microbiology, Technion-Israel Institute of Technology, Haifa, Israel*

<sup>2</sup>*biology, Technion-Israel Institute of Technology, Haifa, Israel*

#### **Background**

Iron acquisition represents a challenge for all organisms due to the low solubility of iron under oxidizing conditions. This challenge is particularly acute for pathogenic microorganisms, due to the iron withholding mechanisms deployed by the host. Many microbial pathogens have therefore evolved mechanisms to extract iron from hemoglobin, the largest iron store in the host, by removing the heme cofactor from the globins and transferring it to the microbe's cytoplasm. The fungal pathogen *Candida albicans* uses a family of conserved extracellular proteins for that purpose, the CFEM proteins <sup>1</sup>.

#### **Objectives**

. The cell wall-anchored CFEM proteins Rbt5 and Pga7 are both able to extract heme from hemoglobin <sup>2</sup>. The heme can then subsequently be transferred from one CFEM protein to the next <sup>2</sup> until it reaches the plasma membrane, whereupon it is endocytosed by a mechanism involving the ESCRT pathway <sup>3</sup>. A third, secreted CFEM protein, Csa2, is shown here to also participate in the heme-iron acquisition relay

#### **Methods**

. Biochemical and structural analysis

#### **Conclusions**

Biochemical and structural analysis of Csa2 reveals that CFEM proteins are unrelated, at either the sequence or structure level, to the known bacterial heme-scavenging proteins, suggesting that microbes have evolved several different independent solutions to the heme-iron acquisition problem.

**Background**

*Trichoderma* includes a great diversity of species, some of them with the ability to control the growth of fungal phytopathogens. Many of these strains produce secondary metabolites that are able to inhibit the growth of their fungal preys. However, pathogens can also produce metabolites that in some cases belong to the same family of those produced by *Trichoderma*.

**Objectives**

In the present work we study the interaction between Harzianum A (HA) produced by *T. arundinaceum* (Ta37) and botrydial (BOT) produced by *Botrytis cinerea*. HA exhibits antifungal activity, and BOT is a strong virulence factor in plant disease.

**Methods**

A procedure of confrontation between these two strains was implemented, followed by the analysis of gene expression by real-time PCR using mycelia isolated from the confrontation areas. To better characterize the regulatory responses produced by HA, the TaDTri5 mutant, isolated by disruption of *tri5* gene and blocked in the synthesis of HA, was also used.

**Conclusions**

It was observed that HA induced expression of genes involved in BOT biosynthesis when HA was added to *B. cinerea* growing alone. However, in confrontation experiments against TaDTri5 the expression of these genes was higher than in confrontation with Ta37, indicating that the mutant must produce some metabolite/s, responsible for such induction. A different metabolite production pattern was described for Ta37 and TaDTri5<sup>(a)</sup>, which is in agreement with the proteomic characterization of these two strains, suggesting that genetic disruption of *tri5* had a systemic effect of the fungal physiology not only restricted to the terpene pathway.

## **CHANGES OF THE ALTERNATIVE OXIDASE ACTIVITY OF BOTRYTIS CINEREA ISOLATES UNDER VARIOUS CONDITIONS**

A. Bérczesné Szojka<sup>1</sup>, A.P. Molnár<sup>2</sup>, M. Asadollah<sup>2</sup>, E. Fekete<sup>2</sup>, L. Karaffa<sup>2</sup>,  
E. Karaffa<sup>1</sup>

<sup>1</sup>*Institute of Food Science, University of Debrecen, Debrecen, Hungary*

<sup>2</sup>*Department of Biochemical Engineering, University of Debrecen, Debrecen, Hungary*

### **Background**

*Botrytis cinerea* (teleomorph *Botryotinia fuckeliana* [de Bary] Whetzel) is the causal agent of grey mould on a wide range of crops. Some of the pesticides used for chemical control inhibit the respiration electron transport chain. Resistance develops rapidly due to the high genetic variability of *B. cinerea*. In addition, a functional alternative oxidase (AOX) may also play a role in the survival of the fungus. Expression of AOX is often increased under biotic and abiotic stress, providing the organism adaptation capacity to different environmental conditions. It may also provide the respiratory electron transport chain an extra capacity when the cytochrome pathway is inhibited or saturated.

*B. cinerea* includes two cryptic species: group I (*B. pseudocinerea*) and group II (*B. cinerea sensu stricto*), which could differ in their pathogenicity, fungicide resistance, host variability and genetic diversity.

### **Objectives**

In this study the differences between the alternative respiratory activity of *B. cinerea* belonging to group I and II were investigated. We also studied the effects of osmotic stress and the temperatures on the respiratory system.

### **Methods**

Measurements were carried out and analyzed with polarographic oxygen electrode system. The cytochrome pathway was inhibited with KCN while SHAM was used for blocking the alternative respiration.

### **Conclusions**

More intense alternative respiratory activity was observed in group II isolates under optimal growth conditions. The alternative pathway was more profoundly induced by osmotic and temperature stress compared to the cytochrome pathway, and this

correlated well with increased transcript formation of the *aox1* gene encoding the AOX enzyme.

**CHARACTERIZATION OF COMPONENTS PRODUCED BY AUREOBASIDIUM PULLULANS, ANTAGONISTIC AGAINST MANGO ANTHRACNOSE DERIVED BY COLLETOTRICHUM GLEOSPORIOIDES**

C.F. Lee<sup>1</sup>, H.F. Chen<sup>1</sup>

<sup>1</sup>Department of Applied Science, National Hsinchu University of Education, Hsinchu, Taiwan

**Background**

Mango anthracnose derived from *Colletotrichum gleosporioides* reveal severe symptoms in terms of surface pitting, skin browning in the surface of mango fruits.

**Objectives**

In this study, We explore to screen the antagonistic yeasts against mango anthracnose and study the antagonistic mechanisms and characteristics of the components produced by the antagonistic yeasts.

**Methods**

Seven strains of *C. gleosporioides* were isolated from 8 infected mangoes. On the pathogenic test, strain WU2L01-1 could infect mangoes and reveal pitting and skin browning as that of anthracnose, indicating the strain is a phytopathogen to mango.

**Conclusions**

Twelve of 578 yeasts exhibited antagonistic activity against *C. gleosporioides*. These strains were classified into the member of the genus *Aureobasidium*, *Cryptococcus* and *Jaminalia* species, based on the sequences of the LSU D1/D domain of rRNA gene. The antagonistic components were characterized by analyzing the activity of degradative enzyme, siderophore and glycolipid. All the experiments demonstrated that these strains cannot produce high activity of siderophore and degradative enzymes,  $\beta$ -1.3 -glucanase, chitinase, amylase, and ?. While, the extracts from culture broth derived from different yeast strains by methanol, ethyl acetate or dichloromethane were confirmed to have the antagonistic activity against *C. gleosporioides*. The optimum medium was tested and obtained for producing antagonistic components. Till now, strains NN5L07, NN5L08, NN9L05,

GY10L05 and HM4L10 and could produce higher productivity of antagonistic components based on these results.

## **AGROTRANSFORMATION SYSTEM APPLIED IN COLLETOTRICHUM CITRUS PATHOGEN**

E.H. Goulin<sup>1</sup>, C. Glienke<sup>2</sup>, M.A. Machado<sup>3</sup>

<sup>1</sup>*Institute of Biology, State University of Campinas, Campinas, Brazil*

<sup>2</sup>*Genetics, Federal University of Paraná, Curitiba, Brazil*

<sup>3</sup>*Centro de Citricultura Sylvio Moreira, Agronomic Institute of Campinas, Cordeirópolis, Brazil*

### **Background**

Brazil is responsible for a third of world production of orange, as well as for 80% of international orange juice market. The European Union is the main market in this Brazilian agribusiness. But, the citrus crop is affected by a range of pathogens that decrease the production and the business viability. One of these diseases is Postbloom Fruit Drop (PFD) caused by one fungal species from the *Colletotrichum acutatum* species complex, which causes serious losses in citrus fruit production. Many works are being developed to study and control this phytopathogenic fungus.

### **Objectives**

An alternative method to investigate the fungus infection process is the use of fluorescence protein.

### **Methods**

For that, we applied the agrotransformation system to transform a *Colletotrichum* isolate from citrus symptomatic blossom, proven as pathogenic.

### **Conclusions**

The methodology became efficient to insert genes in the fungus. The transformers have the ability to express the red fluorescent protein due the insertion of DsRed gene into the fungal genome. They were evaluated in fluorescence microscopy and is possible to identify spores, apressoria and fungus hyphae. Therewith, we efficiently applied the transformation methodology by *Agrobacterium tumefaciens* in the *Colletotrichum* citrus pathogen and these transformants can be used to infection process studies and evaluated for eventual pathogenic alterations as result of insertion mutagenesis.

## **ESTABLISHMENT OF GENETIC MANIPULATION SYSTEM FOR USTILAGO ESCULENTA**

Z. Ye<sup>1</sup>, J. Yu<sup>1</sup>, Y. Zhang<sup>1</sup>, H. Cui<sup>1</sup>, Z. Ma<sup>1</sup>, X. Yu<sup>1</sup>

<sup>1</sup>College of Life Sciences, China Jiliang University, Hangzhou, China

**Background:** *Ustilago esculenta* is a fungal endophyte that triggers stem swelling of *Zizania latifolia* resulting in an edible aquatic vegetable. To date, characterization of the interaction between *U. esculenta* and *Z. latifolia* remains descriptive due to a lack of genetic manipulation and re-infection strategies.

**Objective:** In this study, a transformation system for *U. esculenta* was developed based on methods developed for *U. maydis* and evaluated.

**Methods:** To improve protoplast yield, regeneration rate and transformation efficiency, we systematically adapted several factors, including enzyme digesting conditions, osmotic pressure stabilizers, vectors and antibiotics. The adapted transformation protocol was confirmed by knocking out the *UeICL* (coding isocitrate lyase) gene and over-expressing the *EGFP* gene. Correct transformants were detected by PCR and fluorescence microscopy analysis.

**Conclusions:** The protocol was optimized that 100 mg fresh fungus yielded the maximum number of protoplasts after digested for 3 hours at 30°C in 2 ml SCS solution containing 15 mg/ml Lywallzyme with the osmotic pressure stabilizer of 0.4 M sucrose. The protoplasts obtained highest regeneration rate when growing on Reg-light-Agar medium containing 0.8 M sucrose. *Bsa*I-mediated Golden Gate Reactions and counter-selection with hygromycin of 50 µg/ml or carboxin of 5 µg/ml were successfully used in constructing plasmids and identifying mutants. Similar to most filamentous fungi, flank length around 1kb with homologous ends was efficient for *U. esculenta*. Some sequences of *U. maydis*, like P<sub>otef</sub> and NLS (nuclear localization signal), worked well in *U. esculenta*. We successfully established a genetic manipulation protocol for *U. esculenta* through protoplast transformation.

**FIRST REPORT OF ANTHRACNOSE ON CASSAVA CAUSED BY *C. GLOEOSPORIOIDES* F. SP. *AESCHYNOMENE* IN THAILAND**

*R. Sangpueak*<sup>1</sup>, *S. Wongkaew*<sup>1</sup>, *N. Buensantea*<sup>1</sup>

<sup>1</sup>*School of Crop Production Technology, Suranaree University of Technology, Nakhon Ratchasima, Thailand*

**Background**

Anthrachnose cassava incited by *Colletotrichum* is a prevalent disease in cassava producing regions.

**Objectives**

The aim of this study was to identify the *Colletotrichum* associated with cassava in Thailand.

**Methods**

Cassava anthracnose symptoms (circular, sunken lesions with spore masses produced in black acervuli) were observed on cassava leaves in Nakhon Sawan, Thailand. Four single-spore isolates were derived from fungal cultures isolated from 4 different infected cassava samples.

**Conclusions**

Colonies grown on HPDA changed from white to grey with an average colony diameter of 8.45x8.60 cm after 7 days. Their conidia were cylindrical and 4.75x 14.00 µm in size. To test the four isolates for pathogenicity, after 3 days, typical anthracnose symptoms had developed on the inoculated cassava leaves but not on that of the control treatment. The pathogen was re-isolated from the inoculated cassava but not from the control cassava. Based upon these morphological and cultural characteristics, the 4 isolates were initially identified as *C. gloeosporioides* f. sp. *aeschynomene*. To confirm identity of the four isolates, their internal transcribed spacer (ITS) regions of ribosomal DNA (rDNA), were amplified with ITS3 and ITS4 universal primers. The amplified DNA sequences of these isolates shared 99% homology with the ITS sequences of *C. gloeosporioides* f. sp. *aeschynomene* in the GenBank (JX131331, KC816043, JX139578 and JX258732). To our knowledge, this is the first report of *C. gloeosporioides* f. sp. *aeschynomene* causing anthracnose on cassava.

## **Background**

“Penja Pepper” (*Piper nigrum* L.) is cultivated in the Penja region of Cameroon. It is famous for its exceptional aroma and taste. However, in Cameroon pepper is attacked by various diseases. Moreover, the support tree used for growing pepper vines in Cameroon, *Spondias mombin*, is also subject to disease attacks.

### **Objectives**

In order to maintain the viability of Penja Pepper cultivation, these diseases must be identified and controlled. The aim of this study was to identify the principal pathogens of black pepper vines and its support tree.

### **Methods**

Samples from pepper vines, *S. mombin* and the soil were collected from various fields in the Penja region. Using a combination of baiting and selective agar medium techniques several potential causal agents were isolated. The isolated microorganisms were identified based on morphology as well as ITS sequencing.

### **Conclusions**

Eight oomycete isolates were obtained from pepper and 18 basidiomycete isolates from either pepper or *S. mombin*. The eight oomycete isolates of Pepper were tentatively identified as *Phytophthora vexans* and/or *P. cucurbitacearum*. The morphological identification of the basidiomycete isolates show that it is an *Armillaria* sp. Pathogenicity tests were carried out with 180 days old pepper plants. The plants were inoculated with discs of mycelium introduced in the soil and on the collar. This is the first time that *Armillaria* is found to be pathogenic to pepper as well as its support

tree *Spondias mombin*. The importance of these finding for controlling these diseases to safeguard the sustainable production of the Penja Pepper of Cameroon is discussed

**CATALASE FROM BACILLUS SP. M10 AND ITS POTENTIAL BIOCONTROL ROLE IN THE PROPHYLACTIC AND SYMPTOMATIC TREATMENT OF THE TOMATO ANTHRACNOSE FUNGUS, COLLETOTRICHUM CAPSICI**

P. Rerngsamran<sup>1</sup>, P. Srikhong<sup>1</sup>

<sup>1</sup>Microbiology, Chulalongkorn University, Bangkok, Thailand

**Background**

Anthrachnose which is caused by *Colletotrichum* spp. is the major disease of tomato crops around the world. Antifungal substances have been reported as biocontrol agents against several phytopathogenic fungi. Previously, *Bacillus* sp. M10 was found to inhibit the growth of several fungal pathogens of tomato including *Colletotrichum capsici*.

**Objectives**

To purify and identify the antifungal protein from *Bacillus* sp. M10, and subsequently determine the effects of the antifungal protein to the fungus and its ability to prevent and/or protect tomato fruits from the post-harvest anthracnose disease caused by *C. capsici*.

**Methods**

Ammonium sulfate precipitation and DEAE anion exchange chromatography were performed to purify the antifungal protein. Excised band from SDS-PAGE was analyzed by MALDI-TOF MS. Light and scanning electron microscopy were used to observe the effects of the protein to the fungus. Finally, prevention and protection of postharvest anthracnose disease using the antifungal protein were evaluated.

**Conclusions**

After 40–60% ammonium sulfate precipitation and DEAE anion exchange chromatography, the antifungal protein was enriched 11-fold and was found to retain a specific activity of 189.57 AU/mg. SDS-PAGE revealed that the purified protein has a molecular weight of ~55.4 kDa. MALDI-TOF MS of the excised, enriched protein band revealed the closest similarity to the vegetative catalase (KatA) from *Bacillus amyloquefaciens*. Microscopic observation showed that the protein induced abnormal hyphal elongation and conidial swelling and rupture. The protein caused a marked inhibition of anthracnose development on tomato fruits. Thus, this putative catalase may potentially be useful as a biocontrol agent against anthracnose disease.

**Fungal pathogenicity in plants**

### **AUXIN ROLE AND PRODUCTION IN CLAVICEPS PURPUREA**

J. Vrabka<sup>1</sup>, M. Hradilová<sup>1</sup>, O. Rypárová<sup>1</sup>, A. Pěňčík<sup>2</sup>, J. Hinsch<sup>3</sup>, P. Tudzynski<sup>3</sup>,  
P. Galuszka<sup>1</sup>

<sup>1</sup>CRH Department of Molecular Biology, Palacky University Olomouc, Olomouc, Czech Republic

<sup>2</sup>CRH Department of Chemical Biology and Genetics, Palacky University Olomouc, Olomouc, Czech Republic

<sup>3</sup>Institute of Plant Biology and Biotechnology, Westfälische Wilhelms-University Münster, Münster, Germany

### **Background**

Biotrophic fungus *Claviceps purpurea* is known as a parasite of monocots, invading mainly rye florets (*Secale cereale*). The late infection is characteristic by the formation of dark purple sclerotia, which are the source of ergot alkaloids, substances used in pharmaceutical industry. During the infection, host plant does not show any symptoms of immune response and fungal hyphae grow unrecognized through the plant tissue. Plant defence responses are driven by phytohormone crosstalk and the fungus might utilize its own phytohormone biosynthesis for the host manipulation. Preliminary results showed that mycelium of *Claviceps purpurea* contains high amount of major auxin – indole-3-acetic acid (IAA).

### **Objectives**

The aim of this work is to characterize an auxin biosynthesis in *Claviceps purpurea* and to determine an auxin role in *Claviceps* infection strategy

### **Methods**

IAA concentration and its precursors and conjugates was analysed by TLC and HPLC coupled with the MS detection. Putative genes participating on different auxin biosynthesis pathways and translocation mechanism were deleted by the homologous recombination and transformants have been characterized upon the infection and in axenic cultures.

### **Conclusions**

Genome data mining and measurements of auxin biosynthesis intermediates identified two possible pathways of IAA biosynthesis in *Claviceps purpurea* based on plant and bacterial models. Detailed characteristic of several deletion mutants and WT showed interested features indicating that auxin is secreted from fungal tissue upon the infection and actively translocated in fungi itself.

**Mycobacteria**

## **ROLE OF TETRAZOLIUM BROMIDE REDUCTION ASSAY IN DIAGNOSIS OF SUSPECTED CASES OF MULTIDRUG RESISTANT(MDR)PULMONARY TUBERCULOSIS**

C.P. Baveja<sup>1</sup>, K. Santhosh<sup>1</sup>, M. Hanif<sup>2</sup>, S.K. Prakash<sup>1</sup>

<sup>1</sup>Microbiology, Maulana Azad Medical College, Delhi, India

<sup>2</sup>Microbiology, New Delhi Tuberculosis Center, Delhi, India

### **Background**

Early detection of multidrug resistant tuberculosis (MDR-TB) is of primary importance for both management & infection control. It is complicating TB control efforts in several low- & middle-income countries. Colorimetric method is one of the useful techniques for early detection of MDR-TB.

### **Objectives**

To evaluate drug susceptibility testing by 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyl-tetrazolium bromide (MTT) assay and proportion method to diagnose suspected cases of MDR-TB.

### **Methods**

Sputum from 37 previously treated smear positive patients with pulmonary tuberculosis having clinical suspicion of MDR-TB were included in the study. Culture from Lowenstein-Jensen(LJ) media was inoculated into 7H9 broth and after 7days the inoculum was tested for isoniazid(INH) & rifampicin(RIF) susceptibility testing by MTT assay. The formation of formazan product after addition of MTT (after 7days) was taken as positive for *Mycobacterium tuberculosis*.

### **Conclusions**

In this study 18 cases were sensitive and 15 cases resistant to isoniazid by MTT assay. Twenty one cases were sensitive and 12 cases resistant by drug susceptibility testing of rifampicin by MTT assay. The sensitivity & specificity of MTT assay for INH was 90% & 100% and for RIF 90.90% & 90.90% respectively. The MTT assay is a simple, low cost susceptibility test that can be completed in approximately 7 days. Due to its high levels of agreement with proportion method, the MTT method has the potential to provide rapid detection of INH & RIF-resistant *M. tuberculosis* in clinical use.

**Methods**

Clinical specimens were cultured and the susceptibilities of isolates to the major ATBDs were tested using the BACTEC MGIT 960 system. In a period of six years, 280 MTC strains are isolated from 10121 clinical samples. A decreasing trend was found on the MTC isolation rates from clinical samples with years (7.5% in 2009 to 1.5% in 2014). Of the 197 (70.4%) isolates were found sensitive to all four tested ATBDs and 83 (29.6%) of the isolates were found resistant to at least one ATBD.

Rate of single drug resistance for isoniazid was 10.4% (n=29), for ethambutol 3.9% (n=11), for streptomycin 2.1% (n=6) and for rifampicin 1.4% (n=4). Resistance rates of isoniazid, which was found as the most resistant drug among others, were decreasing (13.4% to 2.9%) while only rifampicin resistance was increasing (1.2% to 5.9%) by years. Rate of at least isoniazid and rifampicin resistant -multidrug resistant (MDR)- isolates was 9,6% (n=27). Number of MDR isolates was decreasing by years.

### **Conclusions**

Even though TB rates are decreasing by years, persistence of high isoniazid resistance rates and increasing resistance of rifampicin requires more strict applications of precautions and limitation of rifampicin use both for treatment and prophylactic purposes in other diseases than TB.

**EXPLORING THE EVOLUTIONARY SUCCESS OF MYCOBACTERIUM  
TUBERCULOSIS BY INVESTIGATION OF RARE CLINICAL ISOLATES WITH  
SMOOTH COLONY MORPHOLOGY**

E. Boritsch<sup>1</sup>, W. Frigui<sup>1</sup>, A. Cascioferro<sup>1</sup>, W. Malaga<sup>2</sup>, A. Pawlik<sup>1</sup>, M. Orgeur<sup>1</sup>,  
P. Supply<sup>3</sup>, C. Guilhot<sup>2</sup>, R. Brosch<sup>1</sup>

<sup>1</sup>Genomes and Genetics, Institut Pasteur, Paris, France

<sup>2</sup>Pharmacology and Structural Biology, CNRS, Toulouse, France

<sup>3</sup>Center for Infection and Immunity, Institut Pasteur, Lille, France

**Background**

*Mycobacterium tuberculosis*, one of the most successful human pathogens, and other members of the *M. tuberculosis* complex (MTBC) show a mainly clonal population structure with 99.9% of genetic similarity. In contrast to these strains with predominantly rough colony morphology, rare clinical isolates with smooth morphology (*M. canettii*) show a greater genetic divergence yet are less virulent and less persistent.

**Objectives**

In order to better understand the mechanism underlying the smooth/rough variation and its implication in virulence, we are currently investigating smooth and rough morphotypes of *M. canettii* strains in more detail.

**Methods**

Stable smooth and rough morphotypes of different *M. canettii* strains were isolated after several passages on solid medium and were subjected to a whole genome sequence analysis by Illumina technology. Single-end short reads were aligned against the reference genome by using SHRiMP. Lipid analysis was done by chloroform/methanol/water extraction followed by thin layer chromatography.

**Conclusions**

Comparative genome analysis of the smooth and the rough morphotype revealed a difference in the *pks5* gene locus, which codes for a polyketide synthase that was found to be involved in lipooligosaccharide (LOS) synthesis in the fish pathogen *M. marinum*. More detailed analysis of this locus suggested the importance of *pks5* and a gene of the *pap* family (polyketide synthase associated protein) to be involved in

the phenomenon. Thus, the *pks5* locus seems to be involved in the smooth/rough variation in *M. canettii* through production of lipooligosaccharides, which could also play a role in the reduced virulence phenotype.

**IDENTIFICATION OF NONTUBERCULOUS MYCOBACTERIA IN POTABLE AND RECYCLED WATER IN MEXICO CITY UNIVERSITY**

Y.Y. Gómez-Alvarez<sup>1</sup>, L. Lloret y Sánchez<sup>1</sup>, M. Paredes Mendoza<sup>1</sup>, Y. López-Vidal<sup>1</sup>, A.I. Castillo-Rodal<sup>1</sup>

<sup>1</sup>*Microbiología y Parasitología Facultad de Medicina,  
Universidad Nacional Autónoma de México, Mexico City, Mexico*

**Background**

Nontuberculous mycobacteria (NTM) are ubiquitous microorganisms that can act as human pathogens in both, immunocompromised and immunocompetent individuals. Because until now it has not been described human-to-human transmission, the main source appears to be the exposure to water containing the microorganisms. All over the world an increasing number of NTM species with different profiles causing human disease represent a public health threat. However, a fast and reliable method to identify NTM in the water distribution system is lacking. The water distribution system and the recycled water for irrigation of Ciudad Universitaria campus of Universidad Nacional Autónoma de México (UNAM) were screened for NTM. We compared *hsp65* gene and 16S rRNA-23S rRNA (ITS) sequence in its ability to distinguish between NTM closely related species.

**Objectives**

The aim of this work was to compare the ITS and *hsp65* gene PCR-RFLP to identify NTM species isolated from recycled water and human use water in distribution systems of UNAM

**Methods**

56 recycled water samples and 163 potable water samples NTM's were grown in Lowenstein- Jensen medium and Middlebrook 7H10 medium. DNA from the isolated strains were identified by ITS and *hsp65* gene PCR-RFLP specific sequences. Amplifications were digested by HaeIII and CfoI for ITS and HaeIII and BstEII for *hsp65* gene. The electrophoresis gels of digested products were analysed with the Roth and Telenti algorithm.

**Conclusions**

Markers ITS and *hsp65* gene PCR-RFLP identified twelve species. Moreover the use of ITS complemented the *hsp65* restriction profiles. The sequences used are a good molecular tool for NTM species and subspecies identification.

**THE ANALYSIS OF PEDIGREE AMONG MYCOBACTERIUM AVIUM SPP.  
PARATUBERCULOSIS INFECTED DAIRY HERD**

Y.I. CHO<sup>1</sup>, S.J. KANG<sup>1</sup>, C. CHOE<sup>1</sup>, Y.H. JUNG<sup>1</sup>, T.Y. HUR<sup>1</sup>, T.I. KIM<sup>1</sup>, S.K. IM<sup>1</sup>,  
E.G. KWON<sup>1</sup>, H.T. PARK<sup>2</sup>, H.S. YOO<sup>2</sup>

<sup>1</sup>*Department of Animal Resources Development, National Institute of animal science,  
Cheonan, Korea*

<sup>2</sup>*Department of Infectious Disease,  
College of Veterinary Medicine Seoul National University, Seoul, Korea*

**Background**

Johne's disease, chronic granulomatous enteric disease in dairy cattle, is caused by *Mycobacterium avium* spp. *paratuberculosis* (MAP) infection. The prevalence of the pathogen in US dairy farm is an approximately 68% and the pathogen induced \$200 to \$250 million economic loss in US dairy industry due to decreasing milk production and increasing cow replacement costs.

**Objectives**

Analysis of MAP positive pedigree for the evaluation of vertical MAP infection comparison with horizontal infection among dairy herd last 10years.

**Methods**

The serum MAP antibody detection enzyme-linked immunosorbent assay (ELISA) was applied for the identification of MAP infection among dairy herd and the test was performed biannually. The MAP positive or negative dam, offspring, sibling and offspring of sibling were recorded for 10 years (2005-2015).

**Conclusions**

The MAP positive or negative pedigree was constructed based on the ELISA test record and the association of each MAP positive individuals among dairy herd was not related with each other. The result from this study could suggest that the horizontal infection would be more considered MAP transmission rather than vertical infection among dairy herds, and it could provide a guideline of future MAP intervention program among dairy herds.

*<sup>2</sup>Biochemistry and Microbiology, Nelson Mandela Metropolitan University,  
Port Elisabeth, South Africa*

*<sup>3</sup>Tuberculosis Section, National Health Laboratory Services, Port Elisabeth,  
South Africa*

**Background**

Tuberculosis (TB) in both animals and humans is caused by Mycobacterium tuberculosis complex

(MTBC) primarily transmitted by inhalation of aerosolized droplets containing the organism. Multi-drug resistance

(MDR) and extensive drug resistance (XDR) are evolutionary features of Mycobacterium tuberculosis to subvert the antibiotic regimes in place.

**Objectives**

The heavy burden of TB in South Africa motivated the investigation of MTBC prevalence among TB patients, amplification and sequencing of DNA amplicons known to confer resistance to TB drugs in Port Elizabeth.

**Methods**

Three thousand eight hundred and ten (3810) sputum specimens were processed and DNA isolated from the Eastern Cape Province, South Africa. DNA was amplified using the Seeplex® MTB Nested ACE detection assay. The agar-dilution proportion method was used to perform drug-sensitivity testing using 7H10 Middlebrook medium. Target genes known to confer resistance to first and second-line drugs were amplified and the amplicons sequenced.

**Conclusions**

One hundred and ninety (5%) DNA samples tested positive for MTBC and from the resistant profiles of the 190 positive samples, we noted that multidrug-resistant TB was identified in 189 (99.5%) with 190 (100%) patients infected with MTB resistant to isoniazid and 189 (99.5%) having MTB resistant to rifampicin. Other percentages of drug resistance observed including 40% pre-XDR and 60% of XDR. This study provides valuable data on the different kinds of mutations occurring at various target loci in resistant MTBC strains isolated from samples obtained from the Eastern Cape Province and reveal a high incidence of MDR amongst the positive samples from

Eastern Cape Province, South Africa.

**MYCOBACTERIUM TUBERCULOSIS CELLWALL ASSOCIATED PROTEIN  
PROMOTES BACILLARY SURVIVAL BY INHIBITING OXIDATIVE STRESS AND  
AUTOPHAGY PATHWAYS IN MACROPHAGES AND ZEBRAFISH.**

S. Mohanty<sup>1</sup>, A. Sonawane<sup>1</sup>

<sup>1</sup>School of Biotechnology, KIIT University, Bhubaneswar Orissa, India

**Background**

*Mycobacterium tuberculosis* (*Mtb*) cellwall associated glycoproteins are involved in host pathgen interactions and pathogenesis.

**Objectives**

In our study, we identified mannosylated glycoproteins from purified *Mtb* cell wall. Our objective was to functionally elucidate the role of this protein in host immune responses and in pathogenesis.

**Methods**

*Mycobacterium tuberculosis* gene is cloned and expressed in *Mycobacterium smegmatis*. Orthologue of *Mtb* gene in *Mycobacterium marinum* was also deleted. Invasion assay was performed in HCT-116 and intracellular survival assay, ROS, autophagic and MAPK pathways were analyzed in infected macrophages.

**Conclusions**

The PRT activity measurement in *Mycobacterium smegmatis* expressing recombinant gene confirmed the mass spectrometry data. Using *Mycobacterium marinum*-zebrafish and the surrogate *MsmPRT* infection models, we proved that PRT is indeed involved in mycobacterial virulence. Histological and infection assays showed that *M. marinum* mutant was strongly attenuated in adult zebrafish and also survived less in macrophages; whereas infection with wild-type and the complemented PRT *M. marinum* strains showed prominent pathological features such as severe emaciation, skin lesions, hemorrhaging, greater weight loss and more zebrafish death. This intracellular survival reveals inhibition of autophagy, reactive oxygen species and reduced activities of superoxide dismutase and catalase enzymes in infected macrophages. Infection with *MsmPRT* also activated the MAPK pathway, NF- $\kappa$ B and inflammatory cytokines. In summary, we show that a novel mycobacterial mannosylated PRT acts both as a virulence and an immunomodulatory factor, suggesting that it may constitute a novel target for antimycobacterial drugs.

<sup>3</sup>-, Institut for Integrative Cell Biology (I2BC UMR9198) CNRS-Université Paris-Saclay. Centre Muraz Bobo-Dioulasso Burkina Faso., Orsay, France

<sup>4</sup>-, Corpogen Corp., Bogota, Colombia

<sup>5</sup>-, National Tuberculosis and Infectious Diseases University Hospital., Vilnius, Lithuania

**Background**

New cost-effective, portable and personalized molecular methods to predict *Mycobacterium tuberculosis* drug-resistance are needed

**Objectives**

To up-grade 'TB-SPRINT', a previously developed assay that targets simultaneously CRISPR polymorphism and first-line drug resistance, to detect resistance to second-line drugs.

**Methods**

An assay targeting *gyrA* codon 94, *rrs* nucleotides 1401, 1402 and 1484, *eis* promoter -10, -12 and -14, and *embB* codon 306 was built on 16 reference DNA. The previous 59-Plex complexity was thus increased to a 75-Plex. To validate this assay a first set of 111 DNA samples from different geographical origin (Lithuania and Colombia) were blindly analyzed. Thirty-eight samples with pyrosequencing data allowed first estimates of performances.

**Conclusions**

Sensitivity, specificity and overall concordance rates of the first version of TB-SPRINT ultra in comparison with pyrosequencing were: 66.7% (6/9), 96.2% (25/26) and 88.6% (31/35), respectively, for FLQ; 96.2% (25/26), 100% (10/10) and 97.2% (35/36), respectively, for KAN; 90.9% (10/11), 100% (25/25) and 97.2% (35/36),

respectively, for AMK; 100% (2/2), 100% (35/35) and 100% (37/37), respectively, for CAP; and 100% (12/12), 100% (5/5) and 100% (17/17), respectively, for EMB. Altogether, 'TB-SPRINT ultra 1.0" was able to detect most prevalent mutations associated with second-line drug resistance with very good specificities on pure and concentrated samples. We are in the process of increasing sensitivity to broaden the applicability of this test. This work shows that tuberculosis resistance to first- and second-line drugs will soon be available as an 'all-in-one tube" assay. This assay will later be tested on biological samples directly.

**INFECTIOUSNESS RATE IN PULMONARY TUBERCULOSIS PATIENTS WITH  
SMEAR POSITIVE OF SPUTUM IN KASHAN,IRAN**

*R. Razzaghi<sup>1</sup>, M. Momen-Heravi<sup>1</sup>, H. Akbari<sup>1</sup>*

*<sup>1</sup>infectious disease, Kashan University of Medical Sciences, Kashan, Iran*

**Introduction**

Identifying time predictors of sputum smear conversion in patients with pulmonary tuberculosis (TB) could be used for planning and the counseling of TB patients. This study was conducted to assess the duration in which sputum smear was turned negative and end of infectiousness of smear positive in pulmonary tuberculosis patients in Kashan.

**Materials & Methods**

This was a cohort study was conducted on 50 smear positive Tb patients in Kashan from the year 2012 to 2013. Sputum smear was taken from pulmonary TB patients in Moslem TB Control Center. Sputum smear was done at the end of first, 2nd, 3rd, 4th and 8th week of treatment. A questionnaire including demographic information and clinical symptoms in addition to the result of HB and ESR were collected. Data analyzed was performed by SPSS 16.0.

**Results**

The result of analysis indicated that 23(46%) of the AFB smear positive tuberculosis were male and 27(54%) were female. The mean age of the patients was  $54.7 \pm 22.7$  years, while 21(42%) were under the age 49 and 29(58%) were over the age 49 years. The result also showed that 20 (40%) patients were Iranian and 30(60%) was from Afghanistan. The most frequently observed cases (90%) were from urban areas and 68% of the cases were outpatient. The highest frequency of clinical symptoms were fever 36 (72%) and dyspnea 21(42%), respectively. The negative result of sputum smear at the end of 2th week was observed in 8(16%), 3th week in 20 (40%), 4th week in 23(46%) and 8th week in 31(62%) patients, respectively. There was positive smear in 19(38%) patients. There was no significant association between the age, sex, nationality and positive result of smear at the second month of treatment. The result of ANOVA revealed that there was a significant effect of time on the infectiousness.

**Conclusion**

Considering the high rate of smear positive AFB at the end of second month of treatment, assessment of Dots quality and the incident of drug resistance among mycobacterium tuberculosis in Kashan is necessary and important.

## **MULTIPLE COLD ABSCESSSES DUE TO MYCOBACTERIUM TUBERCULOSIS**

*H. Afzali<sup>1</sup>, M. Momen-Heravi<sup>1</sup>*

*<sup>1</sup>infectious disease, Kashan University of Medical Sciences, Kashan, Iran*

### **Background**

The musculoskeletal system involvement of tuberculosis (TB) other than spinal TB is a rare and less-known entity. Furthermore symptoms of musculoskeletal involvement of TB infection are non-specific, relatively slow and indolent

### **Objectives**

We report a 55-year-old patient suffering multiple cold abscesses in adjacent soft tissues; emphasising significant clinical and imaging findings

### **Methods**

### ***Case presentation:***

A 55 year old man from Kashan-Iran presented with a 4×4 cm mass without discharge and pain in left buttock from 9 months ago treatment with cephalexin was not successful and other masses appeared in anterior of left leg, left clavicle and under right 12 th rib and right scapula. other complains were 30 kg weight loss, anorexia, anemia and occasional night fever. he was cachectic and pale and afebrile.

there was no tenderness and discharge in all masses. in sonography, collection having debris and gas extending from bone to soft tissue was reported. Mass of elbow was aspirated and acid fast bacilli was seen in smear of aspirated sample. anti TB treatment was started and after 6 months he was well and all masses were disappeared

### **Conclusions**

TB must be considered in differential diagnosis of multiple cold abscesses even in an immunocompetent patient and treatment can be effective even in advanced stage.

## **MOLECULAR TYPING OF MULTIDRUG-RESISTANT AND DRUG SUSCEPTIBLE MYCOBACTERIUM TUBERCULOSIS IN ASIAN COUNTRIES**

C. Nakajima<sup>1</sup>, A. Poudel<sup>1</sup>, Z. Rahim<sup>2</sup>, A. Tamaru<sup>3</sup>, B. Maharjan<sup>4</sup>, Y. Suzuki<sup>1</sup>

<sup>1</sup>*Division of Bioresources, Hokkaido University Research Center for Zoonosis Control, Sapporo, Japan*

<sup>2</sup>*Tuberculosis Laboratory, International Centre for Diarrhoeal Disease Research Bangladesh, Dhaka, Bangladesh*

<sup>3</sup>*Department of Infectious Diseases, Osaka Prefectural Institute of Public Health, Osaka, Japan*

<sup>4</sup>*Tuberculosis Laboratory, German Nepal Tuberculosis Project, Kathmandu, Nepal*

### **Background**

Emergence and spread of multidrug-resistant *Mycobacterium tuberculosis* (MDR-TB) is a serious problem. The treatment needs significantly longer period than in drug susceptible TB and the outcome tends to be disappointing.

### **Objectives**

To understand the mechanism of the development of MDR-TB, we should have information about the genetic background of each *M. tuberculosis* strain. In current study, we collected TB isolates in three Asian countries, Nepal, Bangladesh and Japan, and compared the genetic characteristics between MDR-TB and drug susceptible TB groups.

### **Methods**

TB isolates were collected in each country as follows and the spoligotype was determined, Nepal: 154 MDR-TB and 95 susceptible, Bangladesh: 182 MDR-TB and 50 susceptible, Japan: 88 MDR-TB and 29 susceptible. In MDR-TB, drug resistance determining regions of *rpoB*, *katG* and *inhA* were also analyzed.

### **Conclusions**

In current study, we found some of the spoligotype lineages increased its percentage among MDR-TB, e.g. Beijing type and T1 (SIT53), which seemed to suggest their clonal expansion. Those isolates usually possessed a so-called low-fitness-cost mutation, *katG* G944C, and they might have additional advantageous characteristics.

Further investigation seems to be needed to elucidate the mechanism of the emergence of transmissible MDR-TB to prevent the spread of the lethal pathogen.

**Background**

The reemergence of tuberculosis worldwide has forced efforts to control infections caused by mycobacteria, developing tools to assist in the diagnosis of early, quickly and efficiently, with the aim of reducing morbidity related to Mycobacteria.

**Objectives**

The aim of this work was to detect and differentiate between an infection caused by *Mycobacterium tuberculosis* complex (MTBC) and atypical mycobacteria (NTM) in patients with clinically suspected pulmonary tuberculosis.

**Methods**

Multiplex PCR for detection of CMTB and NTM was assessed; 120 sputum samples were collect from patients with suspected TB, which were divided for PCR analysis and culture.

**Conclusions**

In 39.2% of the samples, mycobacterial DNA was detected; by culture, only 12.5% were positive. These results highlight the importance of the implementation of molecular techniques in the detection of mycobacterial infection with clinical correspondence. In the samples we detect MTBC (38%), *M. avium* (4.2%), *M. intracellulare* (4.2%); *M. indicus* (2.1%), and the remaining 51.5% identification was not possible since only the 16S rRNA and rpoB genes were detected, representing a high percentage of infection NTM, most of these samples were not possible to cultured. In previous years it has been detect by culturing *M. fortuitum* infection, the next step is to design specific primers for the precise identification of the NTM that represent a high percentage of infection in the population of Oaxaca.

**RAPID DIAGNOSIS OF MYCOBACTERIUM TUBERCULOSIS WITH TRUENAT  
MTB: A NEAR CARE APPROACH**

C. Nikam<sup>1</sup>, C. Nair<sup>2</sup>, A. Shetty<sup>1</sup>, C. Rodrigues<sup>1</sup>

<sup>1</sup>*Microbiology, P. D. Hinduja National Hospital, Mumbai, India*

<sup>2</sup>*Microbiology, bigtec laboratories, Bangalore, India*

**Background**

Control of the global Tuberculosis (TB) burden is hindered by the lack of a simple and effective diagnostic test that can be utilized in resource-limited settings. There has been considerable interest in the miniaturization of the PCR platform as this would confer advantages such as reduction in cost of instruments and tests, faster turnaround times and enhancement in the availability and accessibility of PCR tests in resource-poor geographies. With the combined advantages of affordability, simplicity in operations, diagnostic sensitivity and portability, micro-PCR devices are strong candidates for widescale use among the peripheral laboratories of India

**Objectives**

Objectives are as follows:

## Methods

We evaluated the performance of Truenat MTBTM, a chip-based nucleic acid amplification test in the detection of Mycobacterium tuberculosis (MTB) in clinical sputum specimens from 226 patients with suspected pulmonary tuberculosis (TB). The test involved sputum processing using Trueprep-MAGTM (nanoparticle-based protocol run on a battery-operated device) and real-time PCR performed on the Truelab UnoTM analyzer (handheld, battery-operated thermal cycler). Specimens were also examined for presence of MTB using smear microscopy, liquid culture and an in-house nested PCR protocol. Results were assessed in comparison to a composite reference standard (CRS) consisting of smear and culture results, clinical treatment and follow-up, and radiology findings.

## Conclusions

This preliminary study shows that the Truenat MTB test allows detection of TB in approximately one hour and can be utilized in near-care settings to provide quick and accurate diagnosis.

<sup>2</sup>Department of Microbiology, Chungnam National University School of Medicine,  
Daejeon, Korea

### **Background**

Isoniazid (INH) is known to have a bactericidal action against actively replicating *M. tuberculosis* (Mtb). However, it has little effects against slowly replicating bacilli. Mtb reverts from nongrowing bacilli in M1 macrophages to growing bacilli in M2 macrophages and can be susceptible to INH. Therefore, the modification of host immune system is crucial for more effective elimination of persisters in non-replicating state.

### **Objectives**

Therefore, the modification of host immune system is crucial for more effective elimination of persisters in non-replicating state.

### **Methods**

Mouse splenocytes were cultured for 5 days and non-adherent cells were removed. The fermented soybean paste isolated *Bacillus lentus* (BL) was applied to cells for M1 and *Lactobacillus brevis* (LB) isolated from Kimchi, the fermented vegetable, for M2 with 48 hours of infection period. LPS for M1 and IL-4 for M2 were used as a positive control and were run in parallel with every assay. Activated cells were infected with *M. tuberculosis* H37Rv and INH was added 3 days after infection. After 4 days of incubation, number of intracellular Mtb was determined at 14-16 days of infection.

### **Conclusions**

BL had been shown to induce M1. However, LB induced high levels of IL-10 and arginase-1 secretion which is characteristics of M2 macrophage polarization. LB was shown to induce M2 allowing the replication of mycobacteria that increased the efficacy of INH. It could be concluded that the combined use of anti-tuberculosis chemotherapy and immunotherapeutic microbiology might be more effective for eradication of persisters Mtb in macrophages.

## **IDENTIFICATION OF A PUTATIVE TETR REGULATOR IN MYCOBACTERIUM SMEGMATIS**

F. Perrone<sup>1</sup>, G. Merola<sup>1</sup>, V. Vastano<sup>1</sup>, R. Marasco<sup>1</sup>, M. Sacco<sup>1</sup>, L. Muscariello<sup>1</sup>

<sup>1</sup>*Dipartimento di Scienze e Tecnologie Ambientali Biologiche e Farmaceutiche, S.U.N., Caserta, Italy*

### **Background**

*Mycobacterium tuberculosis* (MTB) is able to survive under physical chemical insults, such as nitrosative and acid stress, within the macrophage host niche. By gene expression studies under stress conditions in the model organism *Mycobacterium smegmatis* mc<sup>2</sup>155 we show the down regulation of the *MSMEG\_3765* gene, whose deduced amino acid sequence shares 74% identity with *Mycobacterium tuberculosis* H37Rv *Rv1685c* gene product. Both genes are defined as members of TetR transcriptional regulators, often serving as repressors.

### **Objectives**

Role of the *MSMEG\_3765* gene in stress response. Isolation and characterization of a *M.smegmatis* mutant strain, carrying a null mutation in *MSMEG\_3765*.

### **Methods**

Transcriptional analysis of the *MSMEG\_3765* locus was performed by RT-PCR; the *MSMEG\_3765* gene expression was evaluated by Real Time PCR after acid-nitrosative multi-stress.

The mutant strain was constructed by a two step homologous recombination process. The upstream and downstream regions of *MSMEG\_3765* (1-Kb flanking region) were cloned into a pNIL series vector together with marker genes obtained from the pGOAL series, leading to a suicide delivery system. The pFP1 recombinant vector was used to transform *M.smegmatis* competent cells, and the *M.smegmatis*  $\Delta 3765$  mutant strain was isolated.

### **Conclusions**

The *MSMEG\_3765* was shown to be the last of a four genes operon. Real Time PCR analysis revealed that *MSMEG\_3765* is four times less expressed under acid-nitrosative multi-stress than standard growth conditions. To elucidate the role of *MSMEG\_3765* gene under stress conditions, stress survival and proteome analyses of mutant strain are in progress.

**INCIDENCE OF PARATUBERCULOSIS IN WILD RUMINANTS IN BULGARIA -  
FIRST VETERINARY STUDY WITH IMPLEMENTED COMPLEX DIAGNOSTIC  
TECHNIQUES**

T. Savova-Lalkovska<sup>1</sup>, V. Valcheva<sup>2</sup>, M. Bonovska<sup>2</sup>, H. Najdenski<sup>2</sup>

<sup>1</sup>*Department of Bacteriology,*

*National Diagnostic and Research Veterinary Medical Institute, Sofia, Bulgaria*

<sup>2</sup>*Department of Infectious Microbiology,*

*Institute of Microbiology Bulgarian Academy of Sciences, Sofia, Bulgaria*

Background: Paratuberculosis is one of the most important diseases in cattle and wild animals and with great importance to the international trade market. That is why the application of combination of rapid methods will allow developing a methodology for control of paratuberculosis in Bulgaria, to conduct epidemiological analysis and to assess the risk to animals and humans.

Objectives Application of pathomorphological, microbiological and molecular methods for detection and identification of *Mycobacterium avium* subsp. paratuberculosis (MAP) in tissue samples.

Methods: Study samples included 50 diagnostic materials (mesenteric lymph nodes, small intestine) from deers and mouflons in Bulgaria, suspected for paratuberculosis in the period of 2009-2013. Bacterial cultivation was carried out by using Middlebrook 7H9, Herrolds and Löwenstein-Jensen media. For molecular methods was used MAP Vet kit (Sacace Biotechnologies, Italy).

Results and Conclusions: Typical for MAP pathomorphological lesions were observed in 4 mouflons and 3 deers. MAP isolates grow very well in the Middlebrook 7H9 and Herrold media but did not grow on the Löwenstein-Jensen medium even after 6 months cultivation. The presence of MAP was confirmed by PCR methods. In conclusion, we present here the first veterinary data for diagnostics of paratuberculosis in wild animals in Bulgaria. Development of this scientific field will deepen the knowledge of the properties and early detection of MAP, its significance for infectious pathology, prevention and control and will add new information to the global database for distribution of paratuberculosis in Bulgaria.

**THE PEPTIDOGLYCAN REMODELLING ENZYME RPF<sub>B</sub> OF MYCOBACTERIUM TUBERCULOSIS IS TRANSCRIPTIONALLY REGULATED BY MTR<sub>A</sub> AND SIGMA FACTOR B.**

A. Sharma<sup>1</sup>, A. Chatterjee<sup>1</sup>, S. Gupta<sup>1</sup>, R. Banerjee<sup>1</sup>, S. Manda<sup>2</sup>, J. Mukhopadhyay<sup>1</sup>, J. Basu<sup>1</sup>, M. Kundu<sup>1</sup>

<sup>1</sup>Chemistry, Bose Institute, Kolkata, India

<sup>2</sup>Biochemistry, Bose Institute, Kolkata, India

**Background**

*Mycobacterium tuberculosis*, the causative pathogen of tuberculosis, is a global burden to human health. With the emergence of multi drug resistance, extensive drug resistance and co-infection with HIV, tuberculosis kills 1.7 million people every year. *Mycobacterium tuberculosis* lies dormant within its host over a long time, emerging from dormancy only when conditions are favorable. Both dormancy and reactivation represent processes which are likely to be good therapeutic targets.

**Objectives**

The resuscitation promoting factors are hydrolytic enzymes, which are required for resuscitation of dormant mycobacteria. Resuscitation promoting factor B (RpfB), a peptidoglycan remodelling enzyme is required for reactivation of mycobacterium from chronic infection *in vivo*, underscoring the need to understand its transcriptional regulation.

**Methods**

Transcriptional regulation of *rpfB* has been analyzed using promoter GFP- fusions and in vitro transcription assays. Transcription start point was determined by 5'-RACE. In vitro transcription and EMSA confirmed the recognition of the *rpfB* promoter by sigma factor, SigB and transcription factor, MtrA respectively. Streptavidin pull down assay with a biotinylated DNA fragment and chromatin immunoprecipitation confirmed association of MtrA with the *rpfB* promoter region. Binding site of MtrA on the *rpfB* promoter was identified by DNaseI footprinting assay.

## Conclusions

SigB and MtrA are the two regulators of *rpfB*. MtrAB coordinates cell wall homeostasis. A likely role in cell wall metabolism is strengthened by this report that MtrA regulates expression of the peptidoglycan hydrolase, RpfB. The insights into regulation of *rpfB* are therefore relevant in our quest to uncover new bacterial targets for drug development.

**ROLE OF THE N-TERMINUS OF THE MYCOBACTERIAL MEMBRANE PROTEIN MCTB IN THE LOCALIZATION, STRUCTURE AND RESISTANCE TO COPPER.**

**Background**

We previously described the protein Rv1698 of *Mycobacterium tuberculosis* as involved in an unknown mechanism of resistance to toxic copper ions: mutants of *M. tuberculosis* and *M. smegmatis* lacking functional expression of the gene accumulated copper while wild-type cells did not. Rv1698 is a cell envelope, channel-forming protein and we hypothesized it could be part of a copper efflux machinery. We named it MctB (Mycobacterial copper transport protein B).

**Objectives**

To gain insight on the contribution of MctB to copper resistance, we aimed to characterize its structure.

**Methods**

We solved the structure of recombinant MctB lacking its putative signal peptide by X-ray crystallography. We determined the composition of the mature protein by mass spectrometry analysis. By expressing translational fusions of *mctB* to various reporter genes within phenotypic assays, we investigated the role of the N-terminal hydrophobic  $\alpha$ -helix on the localization and function of the protein. We analyzed the oligomeric state of MctB by size-exclusion chromatography and electron microscopy (EM).

**Conclusions**

In contrast with the established biophysical properties, the crystal structure of recombinant MctB did not show characteristics of a classical channel protein, namely the presence of a channel or contiguous hydrophobic surfaces. We showed that the N-terminus – thought to be a classical signal peptide – (i) is still present in the mature form of MctB, (ii) is required for the translocation and activity of MctB outside the cytosol and (iii) plays a critical role in its oligomerization. Finally, we propose an oligomeric model of MctB based on EM data that helps explain MctB properties.

## **MOLECULAR CHARACTERIZATION OF MYCOBACTERIUM ORYGIS ISOLATES FROM WILD ANIMALS OF NEPAL**

J. Thapa<sup>1</sup>, C. Nakajima<sup>1</sup>, B. Maharjan<sup>2</sup>, A. Poudel<sup>1</sup>, Y. Suzuki<sup>1</sup>

<sup>1</sup>Division of Bioresources, Hokkaido University Research Center for Zoonosis Control, Sapporo, Japan

<sup>2</sup>Tuberculosis Laboratory, German Nepal Tuberculosis Project, Kathmandu, Nepal

### **Background**

*Mycobacterium tuberculosis* complex (MTC) species cause tuberculosis (TB) in humans and animals. Recently, we isolated acid fast bacilli from a spotted deer (*Axis axis*) and a blue bull (*Boselaphus tragocamelus*) in Nepal. They showed atypical colony characteristics.

### **Objectives**

Genotypic characterization of bacterial isolates helps to understand the nature of bacteria. In this study, we aimed to characterize the bacilli isolated from the spotted deer and the blue bull in detail.

### **Methods**

TB suspected lesions from the lung and lymph node in the deer and the lung in the blue bull were collected during postmortem and cultured on Löwenstein-Jensen media. Spoligotyping, multi-locus variable number of tandem repeats analysis (MLVA), region of difference analysis (cfp32, RD9 and RD12) and SNP typing were performed to identify species and to get molecular epidemiological insights.

### **Conclusions**

Isolates from both animals showed a spoligotype SIT587 in SITVIT WEB database as of January 2015. RD analysis results (cfp32: +, RD9 - and RD12-) and SNP data in *gyrB*, *mmpL6*, *TbD1*, *PPE55* and *Rv2042c* identified these isolates to be *M. orygis*. In addition, MLVA of these isolates showed a similar pattern with many other reported *M. orygis* isolates. *M. orygis* have been isolated from many animals and humans of South Asian countries. Our finding may indicate *M. orygis* to be endemic in the sub-continent. Additionally, the identification of a new member of MTC in Nepal may suggest the complexity of tuberculosis in the country. Further investigation with increased sample size and various host animals including human will help to understand the ecology and epidemiology of *M. orygis*.

**MIXED INFECTION IN TUBERCULOSIS: THE CRUCIAL PHENOMENA IN  
OUTCOME OF TREATMENT**

F. Vaziri<sup>1</sup>, E. Hajimir<sup>2</sup>, M. Masoumi<sup>1</sup>, N. Ebrahimzadeh<sup>1</sup>, A. Hadizadeh<sup>1</sup>, S.D. Siadat<sup>1</sup>,  
A.R. Bahrmand<sup>1</sup>

<sup>1</sup>*Mycobacteriology and Pulmonary Research Department, Pasteur Institute of Iran,  
Tehran, Iran*

<sup>2</sup>*Microbiology Department, Islamic Azad University Zanjan branch, Tehran, Iran*

**Background**

*Mycobacterium tuberculosis* (MTB) is among the most successful human pathogenic bacteria worldwide and is responsible for extensive morbidity and mortality, with approximately 2 million deaths each year thought to be due to primary infection, reactivation of latent infection, or re-infection with a new strain. Molecular fingerprinting has differentiated the MTB strains. Most of these studies have shown that each patient is infected with one strain. However, by using more sensitive PCR based technique such as MIRU-VNTR, it is possible to determine co infection with multiple strains of MTB.

**Objectives**

The aim of the current study was to determine the prevalence of mixed infection and clonal complexity in Iranian patients by MIRU-VNTR technique. Additionally, we aimed to determine whether mixed infection results in differences in clinical manifestation or response to treatment.

**Methods**

The PCR was designed to amplify a standard set of 24 MIRU-VNTR loci from genomic DNA extracted using primers described by Supply et al. PCR products were electrophoretically separated on 1.8% agarose gels. In addition, the presence of double alleles was confirmed by two independent rounds of PCRs

**Conclusions**

The MIRU-VNTR method was able to identify mixed infection in at least 25% (17/67) of the cases. Mixed infections occur at high prevalence among Iranian TB patients. The presence of multiple strain infections had high impact on the clinical manifestation and response to anti tuberculosis treatment for individual patients.

**PRESENCE OF MUTATIONS IN GENES ASSOCIATED WITH ANTIBIOTIC RESISTANCE IN MYCOBACTERIUM TUBERCULOSIS STRAINS FROM MICHOACÁN, MEXICO**

L. Pérez-Reyes<sup>1</sup>, G. Vázquez-Marrufo<sup>2</sup>, C. Serrato-Morales<sup>3</sup>, W.V. Padilla-Cabrera<sup>3</sup>, M.S. Vázquez-Garcidueñas<sup>1</sup>

<sup>1</sup>*División de Estudios de Posgrado Facultad de Ciencias Médicas y Biológicas "Dr. Ignacio Chávez", Universidad Michoacana de San Nicolás de Hidalgo, Morelia, Mexico*

<sup>2</sup>*Centro Multidisciplinario de Estudios en Biotecnología Facultad de Medicina Veterinaria y Zootecnia, Universidad Michoacana de San Nicolás de Hidalgo, Tarímbaro, Mexico*

<sup>3</sup>*Laboratorio Estatal de Salud Pública, Secretaría de Salud del Estado de Michoacán, Morelia, Mexico*

**Background**

The six-month treatment against tuberculosis involves rifampin, isoniazid, pyrazinamide, ethambutol and streptomycin. Associations between mutations in specific genes (*rpoB* to rifampicin; *katG* and promoter *mabA* to isoniazid; *pncA* to pyrazinamide; *embB* to ethambutol; *rrs* and *rpsL* to streptomycin) and resistance to antibiotics have been reported. The frequency of these mutations varies in each country and region within a country, so in order to design diagnostics tools, the relationship between mutations and first line resistance patterns in each country must be known.

**Objectives**

Identify mutations associated to antibiotic resistance in strains of *M. tuberculosis* from patients in the state of Michoacán, Mexico.

**Methods**

Thirty-three strains of *Mycobacterium tuberculosis* were analyzed. The susceptibility patterns were determined using BACTEC-MGIT. Mutations were detected by PCR amplification, sequencing, and comparison with the TB Drug Resistance Mutation Database.

**Conclusions**

21.2% of the studied strains were resistant to rifampin. The genes *katG* and *rpoB* showed the highest mutation percentage (30.3% and 27.2%, respectively). 54.5% of the strains presented at least one mutation in any of the analyzed genes. Our analysis of resistant strains found both new and previously reported mutations such

as the *katG* Ser315Thr. The four analyzed strains isolated from patients with meningeal tuberculosis showed extensive drug susceptibility of first line antibiotics. Only two of the latter strains had mutations in the *katG* gene: strain 049 with synonymous Ala411Ala mutation having no influence on antibiotics sensitivity, and 040 with Arg463Leu mutation reported as producing resistance in some cases. 62.5% of the strains resistant to drugs showed some resistance mutation.

**VARIATIONS IN THE SEQUENCES OF VIRULENCE GENES HARBORED BY MYCOBACTERIUM TUBERCULOSIS STRAINS FROM MICHOACAN**

*E. Frutos-Hernández*<sup>1</sup>, *G. Vázquez-Marrufo*<sup>2</sup>, *A.L. Guillén-Nepita*<sup>3</sup>, *C. Serrato-Morales*<sup>4</sup>, *W.V. Padilla-Cabrera*<sup>4</sup>, *M.S. Vázquez-Garcidueñas*<sup>1</sup>

<sup>1</sup>*Facultad de Ciencias Médicas y Biológicas "Dr. Ignacio Chávez", Universidad Michoacana de San Nicolás de Hidalgo, Morelia, Mexico*

<sup>2</sup>*CMEB-Facultad de Medicina Veterinaria y Zootecnia, Universidad Michoacana de San Nicolás de Hidalgo, Tarímbaro, Mexico*

<sup>3</sup>*Facultad de Ingeniería, Universidad Autónoma de Querétaro, Querétaro, Mexico*

<sup>4</sup>*Laboratorio Estatal de Salud Pública, Secretaría de Salud del Estado de Michoacán, Morelia, Mexico*

**Background**

The *Mycobacterium tuberculosis* genome contains two large families of genes called *pe* and *ppe*, some of which encode proteins involve in virulence and the evasion of the immune response. These genes are highly polymorphic and these polymorphisms have been associated with the pathogenicity of strains that are presented.

**Objectives**

To find relationships between polymorphisms in *pe/ppe* gene families and certain genotypes.

**Methods**

59 *M. tuberculosis* strains obtained of tuberculosis patients from Michoacán, México, were analyzed. The species, lineage, family and genotype of the strains were previously determined. The *pe\_pgrs18* and *pe\_pgrs26* genes were amplified and sequenced. Polymorphisms were found by alignment with ClustalX and MEGA6 software against homologous sequences retrieved from GenBank.

**Conclusions**

The *pe\_pgrs18* gene sequences from strains belonging to T, LAM and some not previously reported (NPR) families from the Euro American lineage, EAI strains from Indo Oceanic lineage and Beijing strains from East Asia lineage, harbor SNPs in positions 54-266. Sequences from the same gene, but from Harlem, X and different NPR strains from Euro American lineage, NPR strains from Indo Oceanic lineage and Ghana strains from West Africa lineage, showed SNPs and insertions in positions 295-510. The *pe\_pgrs26* gene harbor SNPs, insertions and deletions; X and T strains shared the same SNPs, while EAI strains showed their own set of shared SNPs. Some detected polymorphisms are consistent with previous reports, while others are not. The gene *pe\_pgrs18* was highly polymorphic. There is a relationship between genotypes and certain polymorphisms in *pe* and *ppe* families.

**GENE EXPRESSION PROFILE OF BIOMARKER CANDIDATES IN  
MYCOBACTERIUM AVIUM SUBSP. PARATUBERCULOSIS INFECTED CATTLE**

H.E. Park<sup>1</sup>, H.T. Park<sup>1</sup>, M.K. Shin<sup>1</sup>, Y.B. Im<sup>1</sup>, H.S. Yoo<sup>1</sup>

<sup>1</sup>Department of Infectious Diseases, College of Veterinary Medicine,  
Seoul National University, Seoul, Korea

**Background**

Johne's disease(JD) is a chronic disease of ruminants caused by *Mycobacterium avium* subsp. *paratuberculosis* (MAP). JD has very long incubation periods, resulting in difficulties in diagnosing the disease, especially regarding the fecal shedders of MAP without any clinical signs. Current MAP diagnosis techniques lack sensitivity in the detection of early stage of MAP infection. Therefore, attempts were made to findout biomarker to detect early responses to MAP infection.

**Objectives**

To develop enhanced diagnosis of early stage of MAP infection, biomarkers were evaluated by analysis of immune-related genes in MAP-infected cattle.

**Methods**

Total RNA was extracted from whole blood of 32 cattle characterized by ELISA and IS900/IS-MAP PCR. Expression of 24 genes was analyzed by real-time PCR to validate the biomarker candidates. The expression level was determined by the 2<sup>- $\Delta\Delta$ Ct</sup> method using  $\beta$ -actin, as a reference. The expression level was compared to the control group to determine the expression-fold change of each gene.

**Conclusions**

Based on the present study, four biomarker candidates showing significant changes were proposed as potential biomarkers of JD. CCL4 and CXCR3 expression were significantly decreased in group 1. On the contrary, CXCL9 expression was significantly decreased in group 2. KLRB1 expression was significantly increased in group 2. These biomarkers might be used for development of enhanced diagnostic tool of early stage of MAP infection in further study. This work was carried out by the grant from RDA, Korea(Project No. PJ008970012015)

**EVALUATION OF MYCOBACTERIUM AVIUM SUBSP. PARATUBERCULOSIS ANTIGENS TO DETECT SUBCLINICAL STAGE OF INFECTION IN CATTLE**

H.T. Park<sup>1</sup>, M.K. Shin<sup>1</sup>, H.E. Park<sup>1</sup>, Y.I. Cho<sup>2</sup>, H.S. Yoo<sup>1</sup>

<sup>1</sup>Department of Infectious Diseases,

College of Veterinary Medicine Seoul National University, Seoul, Korea

<sup>2</sup>Department of Animal Resources Development,

National Institute of Animal Science Rural Development Administration, Cheonan, Korea

**Background**

Johne's disease, caused by *Mycobacterium avium* subsp. *paratuberculosis*(MAP) is one of the most widespread and economically important disease in cattle. Current diagnostic methods are based on detection of MAP antibodies in milk or serum samples or isolation of causative agent. However, these diagnostic techniques are often not applicable in subclinical infection because of relatively low sensitivity. Therefore, finding new antigen candidates highly react with host immune system has been required.

**Objectives**

To detect subclinical stage of infection effectively, several antigen candidates were selected from previous reports. Selected antigen candidates were analyzed about their efficiency.

**Methods**

Complete gene sequences of antigen candidates were cloned and expressed by cold shock expression system with pCold™ I vectors and One shot® chemically competent *E. coli* Top10 cells. Recombinant proteins were tagged by 6-histidine and purified by His SpinTrap™. Serological samples were prepared from cows with different stages of the disease divided into four groups according to stage of infection. Reactivity with these four groups of sera and each antigen was evaluated by western blot.

**Conclusions**

Total of 9 antigen candidates were selected(MAP0862, MAP3817c, MAP2077c, MAP0860c, MAP3954, MAP3155c, MAP1204, MAP1087, MAP2963c) which have MAP specific and/or have high immune responsibility to infected animals. Using four groups of serological samples, it could be evaluated whether the antigen possibly

detect subclinical infection or not. Possible antigen cocktail will be used for development of sensitive ELISA. This work was carried out with Project No. PJ008970012015.

**COMPLEX INFECTION AS A POTENTIAL MECHANISM FOR HETERO-RESISTANCE AND RIFAMPIN RESISTANCE IN MYCOBACTERIUM TUBERCULOSIS**

C. Zheng<sup>1</sup>, S. Li<sup>1</sup>, H. Sun<sup>1</sup>, M. Luo<sup>2</sup>, Q. Sun<sup>1</sup>

<sup>1</sup>College of Life Sciences, Sichuan University, Chengdu, China

<sup>2</sup>Anti-Tuberculosis, Chengdu Public Health Clinical Center, Chengdu, China

**Background**

Rifampin is a key component of the first-line therapy against *Mycobacterium tuberculosis*. Rifampin resistance was reported to be caused by mutation in *rpoB* gene, while 5% of the resistant strains showed no mutation. Hetero-resistance is considered as the preliminary stage to the full resistance in *M. tuberculosis*.

**Objectives**

This study investigated the possible mechanisms conferring hetero-resistance and rifampin resistance without *rpoB* gene mutations.

**Methods**

Two hundred and twelve clinical isolates were subjected to *rpoB* gene sequencing to examine the occurrences of *rpoB* mutations and hetero-resistance. The standard 24-locus variable-number tandem repeat (VNTR) method was used to identify complex infection, which consisted of mixed infection (the presence of strains with different VNTR patterns at  $\geq 2$  loci in one sample) and clonal heterogeneity (different VNTR patterns at a single locus).

**Conclusions**

We found that 3.8% of isolates ( $n = 8$ ) had rifampin resistance of no mutation in *rpoB* gene, in three among which dual peaks from the sequencing results were revealed and therefore identified as rifampin hetero-resistant. The main peak was wild type and the secondary one was mutated (Cys-526, Leu-531 and Tyr-526). All three hetero-resistant isolates were caused by complex infection (18, 8.5%), which included mixed infection (7, 3.3%) and clonal heterogeneity (11, 5.2%). Rifampin resistance with no mutation in *rpoB* gene was significantly associated with complex infection ( $\chi^2$ , 31.21,  $P < 0.01$ ), especially mixed infection ( $\chi^2$ , 56.78,  $P < 0.01$ ). Accordingly, it is necessary to examine complex infection, a possible mechanism for hetero-resistance and rifampin resistance without *rpoB* gene mutations.

## **CYTOXIC AND ANTIMICROBIAL POTENTIAL OF PREMNA RESINOSA**

N. Al Musayeib<sup>1</sup>, A. Dina<sup>1</sup>, R. Muthana<sup>1</sup>

<sup>1</sup>Pharmacy, King Saud University, Riyadh, Saudi Arabia

### **Background**

Herbal drugs have been used since ancient times as remedies for the treatment of a variety of ailments. *Premna* is a member of family Verbenaceae. Some of *Premna* species are known to exhibit cytotoxic, antimicrobial, antioxidant, antipyretic, hypoglycemic and cardiogenic activities.

### **Objectives**

In this study *P. resinosa* methanolic extract as well as its constituents were evaluated for antimicrobial and cytotoxic activity.

### **Methods**

*Premna resinosa* powdered plant was extracted with methanol and constituents were isolated by different chromatographic techniques and identified by spectroscopic methods. The extracts and compounds were tested for antimicrobial *in vitro* against *Staphylococcus aureus*, *Bacillus subtilis*, *Acinetobacter baumannii*, *E. coli*, *Salmonella typhimurium*, *Shigella flexneri* and *Enterococcus faecalis*. In addition, they were tested against human medulloblastoma (Daoy), human hepatocellular carcinoma (HepG2) and human melanoma (SK-Mel-28).

### **Conclusions**

Seven constituents were identified from *P. resinosa*. They are Quercetin (1), 3-Methoxyquercetin (2), Kaempferol (3), 3-Methoxykaempferol (4), Myricetin 3,7,3'-trimethyl ether (5), Lupeol (6), Stigmasterol (7). The dichloromethane extract exhibited the highest antimicrobial effect, meanwhile, Noticeable cytotoxic activity was shown by the crude methanolic extract against Daoy cell line. The antimicrobial activity of the isolated compounds showed higher sensitivity of Gram-positive bacterial strains than the Gram-negative.

**NEW INSIGHTS IN THE BUTYRATE PHOTOASSIMILATION IN  
RHODOSPIRILLUM RUBRUM S1H**

Q. De Meur<sup>1</sup>, B. Leroy<sup>1</sup>, R. Wattiez<sup>1</sup>

<sup>1</sup>*Proteomics and Microbiology, University of Mons, Mons, Belgium*

**Background**

Purple non-sulfur bacteria display a great metabolic versatility and are able to assimilate volatile fatty acids (VFAs) through photoheterotrophic metabolism. One of these bacteria, Rhodospirillum rubrum S1H, was subsequently selected by the European Space Agency for its ability to metabolize VFAs and to remove them in its bioregenerative life support system.

**Objectives**

Here we aim to offer a better view of the still misunderstood photoheterotrophic metabolism of butyrate.

**Methods**

A global understanding of butyrate photoassimilation in purple non-sulfur bacteria was obtained through a multidisciplinary approach including quantitative SWATH-MS proteomic analysis, activity assays, bacterial growth analysis and VFAs consumption monitoring.

**Conclusions**

Butyrate is partially converted into acetyl-coA. Because R. rubrum is an isocitrate lyase lacking organism, an alternative anaplerotic pathway to glyoxylate cycle should be used to replenish the TCA cycle with intermediates for biosynthesis. We suggest here that butyrate could be converted into propionyl-CoA and succinate through ethylmalonyl-CoA pathway and valine degradation pathway.

We also observed that butyrate assimilation occurs only if carbonate is supplied. In accordance with the observed upregulation of RuBisCO, CO<sub>2</sub> fixation is most probably used as redox balancing reaction necessary to sustain butyrate assimilation.

Finally, we showed an inhibition of the butyrate assimilation by acetate when they are provided together at an equivalent net carbon concentration. This effect could be due

to the observed downregulation of key enzymes of the butyrate assimilation pathway when acetate is used as carbon source.

Altogether our data allows better understanding of metabolic pathway involved in butyrate photoassimilation in *R. rubrum*.

**Microbial cell biology and structure**

## **THE UNIQUE SHEATHS OF METHANOGENIC ARCHAEA ARE FUNCTIONAL AMYLOID STRUCTURES**

M.S. Dueholm<sup>1</sup>, P. Larsen<sup>1</sup>, K. Finster<sup>2</sup>, M.R. Stenvang<sup>3</sup>, G. Christiansen<sup>4</sup>, D. Otzen<sup>3</sup>, P.H. Nielsen<sup>1</sup>

<sup>1</sup>Department of Chemistry and Biosciences, Aalborg University, Aalborg East, Denmark

<sup>2</sup>Department of Biosciences, Aarhus University, Aarhus, Denmark

<sup>3</sup>Department of Molecular Biology and Genetics, Aarhus University, Aarhus, Denmark

<sup>4</sup>Department of Biomedicine, Aarhus University, Aarhus, Denmark

### **Background**

Amyloids are highly organized protein or peptide polymers characterized by a cross- $\beta$ -sheet structure. These protein structures were for many years solely considered an abomination associated with incorrect protein folding, leading to devastating neurodegenerative diseases, such as Alzheimer's disease. However, within the last decade it became clear that the amyloid protein fold has many beneficial roles in nature. In bacteria they are used as adhesive fimbriae and for the coating of spores. Fungi use them to modulate the hydrophobicity of aerial hyphae and spores and in the form of prions as a means of phenotype regulation. In mammals, amyloids are used as a scaffold for the skin pigmentation and as a storage form for hormones. However, functional amyloids have never been shown within the Archaea domain of life.

### **Objectives**

Members of the archaeal genera *Methanospirillum* and *Methanosaeta* grow as filamentous chains of rod-shaped cells within tubular paracrystalline sheaths. These sheaths share many properties with the functional amyloids. They are proteinaceous and display high stability toward chemical and thermal denaturation and display a cross- $\beta$ -sheet structure. Accordingly, we hypothesized that the archaeal sheaths could represent a novel type of functional amyloid.

### **Methods**

We employed amyloid-specific conformation antibodies and biophysical techniques to confirm the amyloid nature of the sheaths.

### **Conclusions**

Our work represents the first report of a functional amyloid from the archaeal domain of life. The amyloid nature explains the extreme resistance of the sheath, the elastic properties that allow penetration of diffusible substrates, and how the sheaths are able to split and elongate outside the cell.

### Microbial cell biology and structure

#### EXTRACELLULAR STRUCTURES OF PELAGIC FORMOSA

T. Fischer<sup>1</sup>, E. Rhiel<sup>2</sup>, S. Littmann<sup>3</sup>, T. Schweder<sup>4</sup>, J. Harder<sup>1</sup>

<sup>1</sup>Microbiology, Max Planck Institute for Marine Microbiology, Bremen, Germany

<sup>2</sup>Institute for Chemistry and Biology of the Marine Environment (ICBM), Carl-von-Ossietzky-University, Oldenburg, Germany

<sup>3</sup>Biogeochemistry, Max Planck Institute for Marine Microbiology, Bremen, Germany

<sup>4</sup>Institute of Pharmacy, Ernst Moritz Arndt University of Greifswald, Greifswald, Germany

#### Background

*Flavobacteria* contribute to the degradation of complex organic matter, in particular proteins and polysaccharides. During the decay of a spring phytoplankton bloom in the German Bight of the North Sea near Helgoland in 2009 a successive occurrence of different *Flavobacteria* clades represented up to 60% of the bacterial community (Teeling, H. *et al.*, 2012). Strains of the genus *Formosa* in the marine clade of *Flavobacteriaceae* were recently isolated from this site (Hahnke, R.L. *et al.*, 2014). Large extracellular structures were detected (Hahnke, R.L. *et al.*, 2014), however their function is still not understood.

#### Objectives

We started to study such appendages to gain new insights into their biological role within the pelagic bacterioplankton.

#### Methods

Light microscopy, transmission electron microscopy (TEM) and scanning electron microscopy (SEM) showed at cells of *Formosa* clade A segmented chain-like appendages with a width between 40 to 100 nm. A first membrane preparation by cells disintegrated by pressure change and by differential centrifugation revealed TonB-dependent receptors, an OmpA protein, one SusD-like protein and two hypothetical proteins in the outer membrane enriched fraction. Similarities in the protein pattern were observed for the other pelagic strain, *Formosa* clade B. In contrast, *Formosa agariphila* isolated from green algae revealed a different protein pattern.

#### Conclusions

In this contribution, we will report the outer membrane/appendage proteome as prepared by different protocols. In addition, the appearance of appendages as

response to the physiological situation of the cells may provide first insight into the ecological importance of these appendages.

**Microbial cell biology and structure**

**INVESTIGATION OF THE SIGNAL LEADING TO SURFACE LOCALIZATION OF LIPOPROTEINS IN CAPNOCYTOPHAGA CANIMORSUS**

F. Lauber<sup>1</sup>, F. Renzi<sup>1</sup>, G.R. Cornelis<sup>1</sup>

<sup>1</sup>URBM, UNamur, Namur, Belgium

**Background**

The gram negative *Bacteroidetes* are prominent members of the human intestinal flora, where they are responsible for the breakdown of all major classes of host and dietary glycans. This ability is encoded by so-called Polysaccharide Utilization Loci (PUL), of which the starch utilization system (Sus) of *B. thetaiotaomicron* is the archetype. The Sus is a cell envelope-associated multiprotein complex characterized by the coordinated action of several proteins and lipoproteins involved in starch binding, degradation and internalization into the periplasm. *Bacteroidetes* genome sequencing projects showed that PUL are a hallmark of the phylum. PUL-encoded lipoproteins are surface exposed and little is known on how these proteins are recognized and targeted to the cell envelope.

**Objectives**

We aimed at understanding how the bacterial cell distinguishes between periplasmic and surface lipoproteins.

**Methods**

We used as model organism *Capnocytophaga canimorsus*, an oral commensal of dogs and cats, which can cause severe human infections. An *in silico* approach allowed the identification of a putative signal region at the N-terminus of the lipoproteins and we therefore performed a mutagenic screen on this region on the PUL-encoded surface mucinase Ccan\_17430. The mucinase surface localization of the N-terminal mutants was detected by monitoring mucin degradation.

**Conclusions**

We found a region needed for protein stability, preventing proteolytic cleavage and/or miss-localization of the protein. Further work is needed to characterize the signal and to determine whether the protein degradation observed for several mutants is due to protein instability or is a consequence of miss-localization.

**THE STACK: A NEW BACTERIAL STRUCTURE ANALYZED IN THE ANTARCTIC BACTERIUM *PSEUDOMONAS DECEPTIONENSIS* M1T BY TEM CRYO-TEM AND TOMOGRAPHY**

E. Mercade<sup>1</sup>, L. Delgado<sup>1</sup>, C. Lopez-Iglesias<sup>2</sup>

<sup>1</sup>Health Microbiology and Parasitology, University of Barcelona, Barcelona, Spain

<sup>2</sup>Cryo-Electron Microscopy Scientific and Technological Centers, University of Barcelona, Barcelona, Spain

**Background**

Improvements in TEM and Cryo-TEM techniques and the use of Cryo-electron tomography (CET) of plunge-frozen whole bacteria and vitreous sections (CETOVIS), allow visualization of biological samples close to their native state, enabling us to refine our knowledge of already known bacterial structures and to discover new ones.

**Objectives**

Application of these techniques to the Antarctic cold-adapted bacterium *Pseudomonas deceptionensis* M1<sup>T</sup> to demonstrate the existence of a previously undescribed cytoplasmic structure.

**Methods**

We used cryo-immobilization of specimens by rapid cooling followed by freeze substitution (FS) and sectioning, freeze fracture (FF) and observation of replica, cryoelectron microscopy of vitreous sections (CEMOVIS) and CET of plunge-frozen whole bacteria and vitreous sections to analyze this new structure.

**Conclusions**

*P. deceptionensis* M1<sup>T</sup> and other bacteria contain a new structure we termed 'Stack'. Each 'Stack' consisted of a pile of oval disc-like subunits, each disc being surrounded by a lipid bilayer membrane. They are found at different locations within the cell cytoplasm, in variable number, separately or grouped together, very close to the plasma membrane (PM) and oriented at different angles (from 35° to 90°) to the PM. Stacks did not appear to be invaginations of the PM. Regardless of their position, stacks were mostly observed very close to DNA fibers. This new structure deserves further study to refine its configuration and to establish whether its function could be related to chromosome dynamics.

**STRUCTURAL AND FUNCTIONAL INSIGHT IN THE *HELICOBACTER PYLORI* BLOOD GROUP ANTIGEN BINDING ADHESIN BAB A**

K. Moonens<sup>1</sup>, S. Subedi<sup>1</sup>, E. Romač<sup>2</sup>, G. Castaldo<sup>1</sup>, A. Lo<sup>1</sup>, S. Oscarson<sup>3</sup>,  
S. Muyldermans<sup>2</sup>, T. Borén<sup>4</sup>, H. Remaut<sup>1</sup>

<sup>1</sup>Structural Molecular Microbiology, Vrije Universiteit Brussel, Brussels, Belgium

<sup>2</sup>Research Group Cellular and Molecular Immunology, Vrije Universiteit Brussel, Brussels, Belgium

<sup>3</sup>Centre for Synthesis and Chemical Biology, University College Dublin, Dublin, Ireland

<sup>4</sup>Medical Biochemistry and Biophysics, Umeå universitet, Umeå, Sweden

**Background**

*Helicobacter pylori* is one of the most successful human pathogens, chronically infecting up to half the world population and thereby causing chronic gastritis, duodenal ulcers and even gastric cancer. The blood group antigen binding adhesin (BabA) of *H. pylori* mediates attachment to stomach glycoreceptors containing ABO and Lewis b blood group antigens.

**Objectives**

Our aim was to gain structural insight in the interaction between BabA and ABO/Lewis b blood group antigens.

**Methods**

BabA belongs to a paralogous family of *Helicobacter* outer membrane proteins (Hops) and we demonstrate BabA to feature a novel topology with an OmpA-like 8-stranded non-contiguous  $\beta$ -barrel that is disrupted by an extracellular domain that mediates the adhesive properties to BabA. The crystal and small angle X-ray scattering structure for the BabA extracellular domain reveals a two-domain architecture composed of an  $\alpha$ -helical head domain and a coiled-coil stem domain making the connection to the  $\beta$ -barrel domain. The X-ray structure of the BabA ectodomain bound to its natural glycan receptor Lewis b is presented. Receptor binding is located in a small subdomain grafted into the conserved head domain and critically depends on a disulphide-bound loop in the binding site. The ligand-bound structures of two BabA isomorphs provide a molecular rationalization of the observed blood group antigen polymorphisms in *H. pylori* clinical isolates.

**Conclusions**

Our results represent the first structural insight in how the important human pathogen *H. pylori* recognizes and interacts with its human host.

**FEMS-1009**

## **FUNCTIONAL STUDIES ON THE HMG-COA REDUCTASE GENES OF MUCOR CIRCINELLOIDES**

T. Papp<sup>1</sup>, G. Nagy<sup>1</sup>, D. Toth<sup>1</sup>, O. Pall<sup>1</sup>, C. Vagvolgyi<sup>1</sup>

<sup>1</sup>*Department of Microbiology Faculty of Science and Informatics,  
University of Szeged, Szeged, Hungary*

### **Background**

Terpenoids have several biological functions. Among others, members of this family of chemical compounds are cell membrane components (e.g. ergosterol in fungi), pigments (e.g. carotenoids) or functional groups of certain proteins (e.g. RAS proteins). HMG-CoA reductase is a membrane anchored protein catalysing the central step of the acetate-mevalonate pathway of the terpenoid biosynthesis. Genome of the carotenoid producing zygomycete fungus *Mucor circinelloides* contains three HMG-CoA reductase genes (i.e. *hmgR1*, *hmgR2* and *hmgR3*). Earlier, we analysed the expression of these genes under different growth conditions by qPCR studies (1).

### **Objectives**

In this study, function of these genes and subcellular localization of the encoded proteins were analysed. Functional studies were carried out by overexpression and silencing the three genes.

### **Methods**

For silencing, the antisense RNA technique was used. Carotene and ergosterol content and morphology of the overexpressed and silenced transformants were examined. To analyse the subcellular localization of the enzymes, they were fused with the green fluorescent protein and different dyes were used to analyse their co-localization to different compartments of the cell.

### **Conclusions**

Our results suggest that HMGR2 and HMGR3 co-localize to the endoplasmic reticulum. HMGR2 plays role in the general isoprenoid biosynthesis, while HMGR3 is especially active under anaerobic growth condition and participates in the morphogenesis and the germination of the spores.

This study was supported by the grant OTKA NN106394 and the Hungarian-German Intergovernmental S & T Cooperation Programme TÉT\_12\_DE-1-2013-0009.

## **OUTER-INNER MEMBRANE VESICLES NATURALLY SECRETED BY GRAM-NEGATIVE PATHOGENIC BACTERIA**

C. Perez Cruz<sup>1</sup>, C. López-Iglesias<sup>2</sup>, E. Mercade<sup>1</sup>

<sup>1</sup>Health Microbiology and Parasitology, University of Barcelona, Barcelona, Spain

<sup>2</sup>Scientific and technological centers, University of Barcelona, Barcelona, Spain

### **Background**

Outer-inner membrane vesicles (O-IMVs) were recently described as a new type of membrane vesicle (MV) secreted by the Antarctic bacterium *Shewanella vesiculosa* M7<sup>T</sup>. Their formation is characterized by the protrusion of both outer and plasma membranes, which pulls cytoplasmic components into the vesicles [1].

### **Objectives**

The aim of the current study was to determine whether these new O-IMVs are also secreted by pathogenic Gram-negative bacteria whose MVs have been repeatedly reported to contain cytoplasmic components and DNA.

### **Methods**

For this purpose, three pathogenic bacteria: *Pseudomonas aeruginosa* PAO1, *Acinetobacter baumannii* AB41 and *Neisseria gonorrhoeae* DSM15130 and their derived MVs were analyzed by Transmission Electron Microscopy (TEM) and Cryo-TEM. The presence of the cytoplasmic constituents such as DNA and ATP was also evaluated. The encapsulation of DNA inside the O-IMVs was confirmed by gold DNA immunolabeling. A proteomic analysis of *N. gonorrhoeae*-derived membrane vesicles was performed to identify proteins from the cytoplasm and plasma membrane.

### **Conclusions**

TEM and Cryo-TEM techniques enabled us to demonstrate that Gram-negative pathogenic bacteria produce the recently described new type of vesicles, O-IMVs, together with conventional outer membrane vesicles (OMVs). The existence of O-IMV extends the hitherto uniform definition of MVs in Gram-negative bacteria and explains the presence of components in MVs such as DNA, cytoplasmic and inner membrane proteins, as well as ATP [2].

## **ADAPTATION OF THE BACTERIAL CHEMOTAXIS SYSTEM TO THE ARCHAEAL MOTILITY MACHINERY**

T.E.F. Quax<sup>1</sup>, J. Schuhmacher<sup>2</sup>, G. Bange<sup>2</sup>, S.V. Albers<sup>1</sup>

<sup>1</sup>*Institute of Biology II - Microbiology, University of Freiburg, Freiburg, Germany*

<sup>2</sup>*Analysis and Design of Metabolic Networks, LOEWE-Centrum of Synthetic Microbiology, Marburg, Germany*

### **Background**

The ability to sense and respond to external stimuli is a key feature of all living organisms. Motility is essential to achieve this goal. Archaea are able to swim using a rotating surface structure, the archaellum. It functions analogous to the bacterial flagellum, but its components are unrelated. Instead the archaellum subunits are homologous to components of type IV pili. In bacteria, transfer of external stimuli to the flagellum is mediated by the chemotaxis system. The response regulator CheY plays herein a central role. Euryarchaea display photoaxis, aerotaxis and chemotaxis. Euryarchaea have acquired chemotaxis components from bacteria via horizontal gene transfer. This raises the question how the bacterial chemotaxis machinery has been evolutionary adapted in order to interact with subunits of the archaeal motility structure.

### **Objectives**

We aim to elucidate the functional and structural details interaction of the archaeal CheY with the archaellum motor complex to alter the direction of swimming.

### **Methods**

We have applied crystallography to reveal the structure of the euryarchaeal CheY in 1.6 Å resolution. In addition we have determined its phosphorylation state, as well as that of CheA. CheA is an upstream chemotaxis signaling component, which in bacteria is responsible for phosphorylation of CheY.

### **Conclusions**

The crystal structure of the archaeal CheY shows high similarity to the bacterial CheY. However, the interface of flagellum interaction is very basic in the bacterial CheY, while this same site shows a negative charge in the archaeal CheY. This suggests that the archaeal CheY is structurally adapted for interaction with the archaellum.

## **IDENTIFICATION OF NOVEL BINDING PARTNERS OF CAMPYLOBACTER JEJUNI FLAGELLINS**

K.A. Radomska<sup>1</sup>, M.M.S.M. Wösten<sup>1</sup>, J.A. Wagenaar<sup>1</sup>, J.P.M. van Putten<sup>1</sup>

<sup>1</sup>Department of Infectious Diseases & Immunology, Utrecht University, Utrecht, Netherlands

### **Background**

Flagella are propeller-like structures embedded in the bacterial envelope, which allow bacteria to swim in directions dictated by diverse sensory signals. In many pathogenic bacterial species, flagellar motility is required to reach the ultimate infection niche and to establish infection. The human pathogen *Campylobacter jejuni* is a highly motile organism that possess a flagellum on each pole. As many as 20,000 subunits of flagellin are assembled into a single filament *via* highly regulated process. Most flagellar proteins are bound to specific chaperones before export by the flagella assembly machinery. *C.jejuni* encodes for three different flagellins, however flagellar chaperones have not been characterized yet.

### **Objectives**

Flagellar chaperones are well-studied in Gammaproteobacteria but not Epsilonproteobacteria including the human pathogens: *Campylobacter jejuni* and *Helicobacter pylori*. The goal of this study is to characterize the flagellar chaperones in *C.jejuni*, the main cause of bacterial food-borne infections.

### **Methods**

Potential flagellar chaperones of *C.jejuni* were cloned and expressed in *E. coli*. Interaction of the recombinant putative chaperones with purified *C.jejuni* FlaA flagellin was tested via *in vitro* and *in vivo* pull-down experiments. The effect of targeted mutagenesis of the chaperones on flagella production was tested by a motility soft agar assay and (electron)microscopy methods. Western-blotting and qRT-PCR were used to detect differences in the FlaA, FlaB or FlaC flagellin expression levels.

### **Conclusions**

Targeted mutagenesis of putative flagellar chaperones influenced bacterial motility, flagellin levels and flagella length. The observed phenotype can be explained by direct interaction of chaperones with FlaA flagellin as demonstrated by pull-down experiments.

**LEA PROTEINS ARE INVOLVED ON DESICCATION RESISTANCE AND OTHER ABIOTIC STRESSES IN AZOTOBACTER VINELANDII**

J. RODRIGUEZ<sup>1</sup>, S. Moreno<sup>1</sup>, G. Espin<sup>1</sup>

<sup>1</sup>*Microbiología molecular, Instituto de Biotecnología, Cuernavaca Morelos, Mexico*

**Background**

In plants, the expression of Late Embryogenesis Abundant Proteins (LEA) correlates closely with the acquisition of tolerance against drought, freezing and salinity stresses. In *A. vinelandii* we found two genes with homology sharing identity to putative LEA proteins from *Arabidopsis thaliana*, the sequence of the genes contains a part of the LEA eukaryotic motif, but differs from the distinctive motive found in other bacteria, so this could be an example for the possibility of horizontal gene transfer between domains of life.

**Objectives**

The aim of this work is to analyze if LEA proteins are involved on the resistance to desiccation, heat, freezing and osmotic stress in both cysts and vegetative cells of *A. vinelandii*.

**Fig. 1** Tolerance to osmotic stress caused by a) NaCl and b) Sorbitol in *A. vinelandii* cells

Fig. 4 Tolerance to high temperatures in a) vegetative cells , b) cysts of *A. vinelandii* .

Fig. 5 Tolerance to freezing in *A. vinelandii* vegetative cells.

% Desiccation Resistant Cysts

Strain	WT	LEA1
1	9.52%	1.40%
2	16.23%	0.0%
3	7.25%	2.30%
Mean	11.00%	1.23%

## Methods

We constructed mutants for these genes, LEA1 and LEA2 and a double mutant LEA12. Cysts and vegetative cells were treated to desiccation for 3 months; osmotic stress was caused by different concentrations of NaCl and Sorbitol. We tested the tolerance of these mutants to high temperatures (60°C for 15 minutes) and freezing (-20°C for three month) for both cysts and vegetative cells.

## Conclusions

LEA proteins are necessary to confer tolerance to desiccation on cyst cells after 3 months treatment and are necessary to survive at high osmotic agents concentrations in vegetative cells too. LEA proteins can also protect cyst and vegetative cells against high and low temperatures since LEA mutants were unable to grow at 50°C or -20°C

<sup>1</sup>*Structural Biology Brussels, Vrije Universiteit Brussel, Brussels, Belgium*

<sup>2</sup>*Department of Chemistry, Institute for Structural and Molecular Biology University College London, London, United Kingdom*

**Background**

Curli are proteinacious fibers that constitute the major component of the extracellular matrix in pellicle biofilms in many Gram-negative bacteria.

**Objectives**

Numerous fundamental questions about the curli biogenesis pathway remain unsolved. Curli formation requires a dedicated protein secretion machinery comprised of the outer membrane lipoprotein CsgG responsible for the transport of curli subunits across the outer membrane and two soluble accessory proteins.

Here we propose a novel diffusion-based and entropy-driven transport mechanism that is as a working model for the CsgG translocator.

**Methods**

Recently the X-ray structure of this protein was solved within our group, revealing a nonameric complex embedded in the outer membrane by a 36-stranded  $\beta$ -barrel. Based on this structure and pre-eliminary single-channel results we observe that the CsgG pore on its own is an ungated, non-selective protein secretion channel. As earlier described in literature we confirm that the addition of certain amounts of the CsgE chaperon protein blocks the CsgG pore.

**Conclusions**

Together these findings support the working model we propose. Future structural and single-channel analysis give even more insight in the process and will probe how subunit secretion is coupled with fiber assembly.

<sup>2</sup>Cell Biology and Molecular Genetics, University of Maryland, Maryland, USA

<sup>3</sup>Molecular Microbiology, University of Dundee, Dundee, United Kingdom

<sup>4</sup>Biological Chemistry and Drug Discovery, University of Dundee, Dundee, United Kingdom

**Background**

Group A *Streptococcus* (GAS) is a preeminent Gram-positive human pathogen. GAS expresses a characteristic cell wall polysaccharide, known as Group A Carbohydrate (GAC), consisting of rhamnose and *N*-acetylglucosamine (GlcNAc), which is critical for full virulence. The final step of the four-step dTDP-L-rhamnose biosynthesis process is catalyzed by dTDP-4-dehydrorhamnose reductase (RmlD) in an NAD(P)H-dependent manner. Previous structure elucidation of RmlD from *Salmonella enterica* demonstrated that Mg<sup>2+</sup>-dependent dimerization is essential for enzymatic activity. The first gene in the GAC gene cluster, *gacA*, is annotated as an RmlD enzyme.

**Objectives**

We aimed to identify the structure, function and biological importance of the *gacA* gene product.

**Methods**

We generated recombinant GacA protein for biochemical and structural analysis. Also, a saturated transposon library of GAS was screened by whole genome sequencing (Tn-seq) and subjected to Bayesian analysis to identify essential genes. Finally, *gacA* was expressed in a *S. mutans rmlD* knockout to analyse whether this would restore its attenuated phenotype.

**Conclusions**

GacA catalyses the biosynthesis of dTDP-rhamnose in a novel Mg<sup>2+</sup>-independent monomeric manner. The 1.1 Å high-resolution structure of GacA confirms conservation of key active site residues, but GacA lacks the dimerization motif characteristic for RmlD in Gram-negative bacteria. GacA may therefore represent a new class of monomeric RmlD enzymes. We identified *gacA* as an essential gene and confirmed enzymatic function by restoring the growth and morphology of an *S. mutans rmlD* mutant. Our report provides a framework for future screenings to identify novel inhibitors that interfere with dTDP-rhamnose biosynthesis in human pathogens.

**CYDIV, A CRITICAL PROTEIN IN THE CELL DIVISION IN ANABAENA SP. PCC7120.**

*D. Andrade<sup>1</sup>, C. Trigo<sup>1</sup>, D. Mandakovic<sup>1</sup>, B. Riquelme<sup>1</sup>, M. Vásquez<sup>1</sup>*

*<sup>1</sup>Molecular Genetics and Microbiology, Pontificia Universidad Católica de Chile, Santiago, Chile*

**Background**

Bacterial cell division is a fundamental and complex process that requires coordinated mechanisms for elongation and septal formation in the middle of the cell. Most researches in cyanobacterial division have been focused on identifying proteins that interact specifically with the FtsZ protein, also revealing that the division machinery presents differences in composition and regulation compared to the division of gram-negative and gram-positive model microorganism. Studies carried out in our laboratory have determined a gene common to all filamentous cyanobacteria (cyDiv), which encodes a protein with one transmembrane and coiled-coil domains. The phenotype of the mutant strain in this gene presents serious defects in cell division.

**Objectives**

To determine the participation of CyDiv protein in the cell division process of the filamentous cyanobacteria *Anabaena* sp. PCC7120.

**Methods**

We analyzed CyDiv localization by immunofluorescence generating specific polyclonal antibodies against the protein from a synthetic peptide. Furthermore, using bioinformatic analyses, we predicted the possible role of this protein.

**Conclusions**

We showed that CyDiv is localized in the cell poles and in the middle of the cell depending on the division phase, co-localizing with the Z-ring. These results, together with previous phenotypical observations of the cyDiv mutant, suggest that CyDiv is essential for cell division in filamentous cyanobacteria. In silico analyses determined that this protein has a similar topology to the cellular division proteins FtsB and DivIC, from *E. coli* and *B. subtilis* respectively.

**BIOPHYSICAL CHARACTERIZATION OF A TRIMERIC AUTOTRANSPORTER  
ADHESIN, ATAA, FROM THE HIGHLY ADHESIVE BACTERIUM  
ACINETOBACTER SP. TOL 5**

S. Yoshimoto<sup>1</sup>, H. Nakatani<sup>1</sup>, K. Hori<sup>1</sup>

<sup>1</sup>*Department of Biotechnology, Nagoya University, Nagoya, Japan*

**Background**

The Gram-negative bacterium *Acinetobacter* sp. Tol 5 shows autoagglutinating nature and noteworthy adhesiveness independent of biofilm formation through a trimeric autotransporter adhesin (TAA), namely AtaA. TAA is one of the major outer membrane proteins widely distributing in Gram-negative bacterial species. Many studies have shown that TAAs from pathogens adhere to ECM proteins, such as collagen, fibronectin and laminin. In contrast, we previously reported that AtaA mediates bacterial cell adhesion to various abiotic surfaces nonspecifically. However, we have investigated the adhesive property mediated by AtaA only in a cellular level.

**Objectives**

Here, we report the characteristics of AtaA as a molecule. We attempted to purify the AtaA molecule and characterize its biophysical and adhesive properties.

**Methods**

The structural stabilities in thermal treatment and pH change were analyzed by transmission electron microscopy (TEM) and circular dichroism (CD). The adhesion property of the purified AtaA molecule was analyzed by quartz crystal microbalance (QCM).

**Conclusions**

The TEM images of the purified AtaA showed slightly curved fiber structure of 225 nm in length with two globular domains at the amino-terminal and near the carboxyl terminal. The adhesive function of the purified AtaA remained after pH treatment. In contrast, that of the purified AtaA decreased with disruption of its structure after thermal treatment more than 80°C. These results suggest that AtaA molecule has relatively high resistance against strict conditions and its fiber structure plays crucial role in its adhesiveness to abiotic surfaces.

<sup>4</sup>*Protección de Cultivos, IFAPA Centro Las Torres –Tomejil, Alcalá del Río, Spain*

<sup>5</sup>*Producción Ecológica y Recursos Naturales, IFAPA Centro Las Torres –Tomejil, Alcalá del Río, Spain*

**Background**

Halophytes are highly salt tolerant plants able to survive and flourish in coastal salt marshes and salt steppes. Lebrija marshes are situated at SW-Spain (36° 64' 29" N - 6° 12' 92" O), covering an area of 13000 has. Several halophytes are able to grow in this zone. Among them, we have selected *Arthrocnemum macrostachyum*, a plant with proven desalination capacity, as source for isolating halotolerant rhizosphere microorganisms.

**Objectives**

Isolate halotolerant rhizosphere microorganisms.

**Methods**

A total of two hundred bacteria have been isolated from plants grown in two different zones of the Lebrija-marshes at two different seasons (autumn and summer). These strains have been tested for their capacity to grow under high salinity conditions and six strains have been selected.

Rhizospheric soil samples were suspended and homogenised in sterile mineral buffer. Serial dilutions were plated on Nutrient Agar supplemented with 300 mM NaCl and cycloheximide (100 mg/l), adjusted at pH 7.4, at 28 °C for 5 days.

**Conclusions**

Three of the six strains, named Cs16b, Cs25 and Hvs 18 were unable to grow without salt in the culture media (halophyte strains) being the last one (Hvs18) able to support up to 20% NaCl. The other strains (Hv14b, Hv16 and C14) were halotolerant ones. All of them have been sequenced and characterized. Cs16b, Cs25 and Hv16 have been described as novel species within the genera *Microbulbifer*, *Labrenzia* and *Kokuria*, respectively.

## **EFFECT OF WOOD CREOSOTE ON INTESTINAL MICROBIOTA IN RATS**

K. Cho<sup>1</sup>, J. Kim<sup>2</sup>, J. Kim<sup>1</sup>, D. Yu<sup>1</sup>, Y. Hong<sup>1</sup>, I. Cho<sup>3</sup>

<sup>1</sup>*Animal Resources Technology,*

*Gyeongnam National University of Science & Technology, Jinju, Korea*

<sup>2</sup>*Swine Science & Technology Center,*

*Gyeongnam National University of Science & Technology, Jinju, Korea*

<sup>3</sup>*Biological Sciences, Shilla University, Busan, Korea*

### **Background**

Diarrhea is influenced on specific pathogenic microbes. Wood creosote is an anti-diarrhea medicine to have been used for about 100 years in the northeastern Asia.

### **Objectives**

We investigated the change of intestinal microbiota in rats to be fed with wood creosote.

### **Methods**

Sixty rats (7 weeks old) were divided to 5 groups; control, antibiotic group, 0.2%, 0.4% and 0.8% wood creosote groups. The wood creosote and the antibiotic were supplied with feed for 4 weeks. To analyze intestinal microorganisms, the pyrosequencing was performed with 16S rRNA genes of microorganisms from intestinal contents.

The control group distributed 6 phyla including 229 species of microorganisms, the antibiotic group 7 phyla including 245 species, 0.2% wood creosote group 7 phyla including 284 species, 0.4% wood creosote group 7 phyla including 276 species and 0.8% wood creosote group 7 phyla including 324 species, respectively. *Clostridium* to belong to *Clostridia* that include many species of pathogenic microorganisms was 33.4, 44.3, 37.0, 35.5 and 11.6 per cents in the control group, the antibiotic group, 0.2, 0.4 and 0.8% wood creosote groups, respectively. The wood creosote dose-dependently decreased *Clostridium* in the large intestine.

### **Conclusions**

We think that the supply of the wood creosote increases the diversity of the intestinal microorganisms and inhibits the propagation of specific pathogenic microorganisms.

## **DEEPWATER HORIZON SPILL'S IMPACT ON SHIPWRECK MICROBIOMES AND SURROUNDING ENVIRONMENT**

L. Fitzgerald<sup>1</sup>, A. Cockrell<sup>2</sup>, T. Boyd<sup>1</sup>, C. McGown<sup>3</sup>, P. Fulmer<sup>1</sup>, B. Ringeisen<sup>1</sup>,  
L. Hamdan<sup>3</sup>

<sup>1</sup>Chemistry, Naval Research Laboratory, Washington DC, USA

<sup>2</sup>Postdoc, National Research Council, Washington DC, USA

<sup>3</sup>Environmental Science and Policy, George Mason University, Manassas, USA

### **Background**

Shipwrecks serve as artificial reefs in the deep ocean. Due to their random distribution and inherent diversity compared to the surrounding environment, shipwrecks are ideal ecosystems to study pollution impacts, microbial distributions and marine corrosion.

### **Objectives**

To comparatively assess the *Deepwater Horizon* spill's impacts on shipwreck microbiomes and the synergistic effects on these communities and surrounding environment. Field activities will generate material and environmental samples required to address questions related to contaminant effects resulting from the spill and the interaction of spill related contaminants on the microbiota. Microbial action at each site will be interrogated to determine if exposure to hydrocarbons and dispersant-based chemicals have impacted the artificial reefs.

### **Methods**

Porewater from sediment samples were analyzed by ion chromatography and inductively coupled plasma optical emission spectrometry to quantify major elements. Concentration and stable isotope ratios for sediments were determined using an elemental analyzer interfaced to an Isotope-Ratio Mass Spectrometer (IRMS). The molecular analysis of sediment from wreck sites was performed on the Ion Torrent Personal Genome (PGM) machine to provide a comprehensive assessment of microbiome composition. An analytical pipeline to extract taxonomic information from PGM sequences was completed to provide metabolic functional information from DNA sequences.

### **Conclusions**

Six shipwrecks in the northern Gulf of Mexico were investigated. Various laboratory tasks have been completed since the second field research expedition funded by this project. Taxonomic classification of shipwreck microbiomes and metabolic information extracted from sequence data yielded new understanding of microbial processes associated with shipwrecks in the deep biosphere.

**PREDICTING THE DYNAMICS AND BIODEGRADATION POTENTIAL OF RIVER MICROBIAL COMMUNITIES IN ANTHROPIZED WATERSHEDS: A WET LAB APPROACH.**

L. Goetghebuer<sup>1</sup>, P. Servais<sup>1</sup>, I. George<sup>1</sup>

<sup>1</sup>*Ecology of Aquatic Systems, Université Libre de Bruxelles, Brussels, Belgium*

**Background**

River waters represent less than 0.0002 % of global water resources but they are essential for human life. Yet they are particularly exposed to anthropogenic stresses and risks of degradation. In a context of diminishing access to clean resources, lotic microbial communities play a key role in water self-purification. However they remain largely uncharacterized, and the link between lotic bacterial diversity and bacterial community stability and performance has not been studied.

**Objectives**

The goal of our project is to determine which factors drive the response of lotic microbial communities to organic pollution and how they tolerate, resist, exploit this pollution and/or go back to original status (resilience) downstream sewage outfalls. More specifically, the role of (i) native community structure (both phylogenetic and functional), (ii) wastewater bacteria released with organic matter and (iii) type of disturbance (regular/occasional, low/high loads) are studied using bacterial strains isolated from the Zenne river, Belgium.

**Methods**

Random artificial assemblages of these strains are used to test the effect of microbial community structure (richness, evenness, architecture, metabolic diversity...) on community performance and recovery from stress.

**Conclusions**

We hypothesize that such simplified, “wet lab” approaches can help to develop predictive tools of the dynamics and activity of bacterial communities in urban watersheds and *in fine* contribute to a better protection and restoration of river ecosystem services.

**METATAXONOMIC PROFILING AND METABOLIC POTENTIAL OF TWO SOIL-DERIVED MICROBIAL CONSORTIA SELECTED ON WHEAT STRAW**

D.J. Jimenez Avella<sup>1</sup>, J.D. van Elsas<sup>1</sup>

<sup>1</sup>*Microbial Ecology, University of Groningen, Groningen, Netherlands*

**Background**

Mixed microbial cultures have been proposed as an efficient way to deconstruct plant waste. The characterization of specific microbial consortia could be the starting point for novel biotechnological applications related to the efficient conversion of lignocellulose to cello-oligosaccharides, plastics and/or biofuels

**Objectives**

Here, the diversity, composition and functional profiles of two novel microbial consortia are reported, on the basis of replicated aerobic wheat straw enrichment cultures

**Methods**

Soil as microbial source and three sequential-batches were evaluated by amplicon-pyrosequencing (bacterial 16S rRNA and fungal ITS1) and whole metagenome sequencing

**Conclusions**

Both systems appeared to indeed incite a reshaping of the bacterial communities, with reductions in richness and increases in prevalence of particular members of the Enterobacteriales, Pseudomonadales, Flavobacteriales and Sphingobacteriales. Among the fungal players with high biotechnological relevance, co-existing with bacteria ones, we detected member of the genera *Coniochaeta*, *Acremonium* and *Trichosporon*. Metagenomic analyses revealed an overrepresentation of diverse carbohydrate transporters, plant polysaccharides sensing proteins and several genes encoding enzymes of the glycosyl hydrolase families GH2, GH43, GH92 and GH95 in the two consortia, as compared to the soil inoculum. These analyses are the starting point for synthetic expression systems and could enhance our understanding of microbial lignocellulose bioconversion in engineered or natural soil environments

<sup>3</sup>*Center for Ecological Research, Kyoto University, Kusatsu, Japan*

<sup>4</sup>*National Research Institute of Fisheries Science, Fisheries Research Agency, Yokohama, Japan*

<sup>5</sup>*Graduate School of Agriculture, Kyoto University, Yokohama, Japan*

### **Background**

Identifying the drivers of plant community succession is a central theme in ecology. Research has shown that plant-soil feedbacks drive community assembly and has inspired many theories of species diversity. An important unsettled issue is whether mycorrhizas mediate plant-soil feedbacks to determine tree community succession.

### **Objectives**

We show that ectomycorrhizas (but not arbuscular mycorrhizas) define interactions among trees and therefore have the ability to trigger and eventually to arrest tree community succession.

### **Methods**

Using reciprocal invasion design with ectomycorrhizal mycorrhizal (EcM) and arbuscular mycorrhizal (AM) tree species, we tested for the potential for shared compatible mycorrhizal fungi to modulate interactions between invading seedlings ('daughters') understorey and resident trees (mycorrhizal 'mothers') in replicate mesocosms.

### **Conclusions**

Characterizing mycorrhizal fungal communities using pyrosequencing, we find that EcM seedlings favored EcM fungi over AM fungi, but AM seedlings exhibited no mycorrhizal preference. The results from growth survey and physiochemical data confirm (i) invasibility of EcM fungi (and hence EcM seedlings) to AM-dominated communities, (ii) detrimental effects of EcM fungal diversity on AM daughters and mothers, and (iii) the ability of EcM fungal network in reducing the relative growth of EcM daughters to EcM mothers. The results demonstrate that invasion of EcM fungi facilitates establishment of EcM trees on the presence of AM trees, and eventually arrests the relative growth of EcM daughters to EcM mothers, a relationship potentially regulating tree community succession. The observed shifts from positive to negative plant-soil feedbacks involving EcM may explain why the climax temperate forests are predominantly ectomycorrhizal.

<sup>4</sup>Laboratory of Microbiology (LM-Ugent), Ghent University, Ghent, Belgium

### **Background**

Aerobic methanotrophic bacteria are capable of both energy conservation and growth with methane as carbon source. Next to this unique feature they can be primary producers, supporting microbial foodwebs, particularly in aquatic environments. Recently it has been suggested that disparate microbial populations, including the methanotrophs are responsible for methane cycling rather than individual methanotrophs. The interactions between methanotrophs and heterotrophic partners have also been shown to be highly specific and beneficial to the rate of methane oxidation. Methane is an important greenhouse gas and methanotrophic communities could be used for both mitigation and biotechnological applications, warranting investigations into their composition.

### **Objectives**

The aim of this work was to gain insight in the primary and secondary consumers from an active laboratory methanotrophic enrichment culture.

### **Methods**

A methanotrophic mixed culture from various sources was incubated with both <sup>13</sup>C labeled methane and <sup>12</sup>C methane. At several points in time the 16S rRNA genes of the community were amplicon sequenced from both the light and heavy fractions to identify the first partners to incorporate labeled methane (methanotrophs and primary consumers) and later partners (secondary consumers). Interesting timepoints were selected based upon denaturing gradient gel electrophoresis profiles at 24 and 60 hours of incubation.

### **Conclusions**

The main methanotrophic community driver was *Methylophilus* sp. Unique primary partners in the heavy fraction at 24h were members of the genera *Acidivorax*, *Curvibacter*, *Pseudoxanthomonas*, *Methylophilus* and *Rhodobacter*. At 60h the genera *Sphingobacter*, *Kaistia*, *Sphingomonas*, *Flavobacterium*, and *Methylobacillus* represented the heavy fraction. Isolation of these partners from the community could help elucidate their influence on methane cycling.

## **IMPROVEMENT OF SEQUENCE-BASED BACTERIA IDENTIFICATION IN POLYBACTERIAL SPECIMENS BY RIPSEQ MIXED SOFTWARE**

I. Kotásková<sup>1</sup>, H. Obručová<sup>1</sup>, V. Holá<sup>2</sup>, K. Adamcová<sup>1</sup>, B. Mališová<sup>1</sup>, T. Freiburger<sup>1</sup>

<sup>1</sup>Molecular and Genetics Laboratory,

Center for Cardiovascular Surgery and Transplantation, Brno, Czech Republic

<sup>2</sup>Department of Microbiology, St. Anne's Faculty Hospital, Brno, Czech Republic

### **Background**

Sequencing-based molecular methods have become a substantial tool in microbiology but analysis of polybacterial samples still remains a methodological challenge. RipSeq Mixed represents software-based technique, when up to 3 mixed chromatograms can be separated *in silico*, however this possibility can be inadequate for some types of microbiological material.

### **Objectives**

We present the use of Denaturing Gradient Gel Electrophoresis (DGGE) followed by sequencing in combination with analysis of polymicrobial sequences by RipSeq Mixed software. Combination of these methods was used for detection of bacteria in urine and ureteral stent sonicates. Bacteria were detected also by culture-dependent techniques.

### **Methods**

A total of 45 specimens of 15 patients were collected. The V3-V5 region of the 16S *rRNA* gene was amplified and multiple length homogeneous amplicons were separated by DGGE. Bands were excised and reamplified PCR products were sequenced. RipSeq Mixed software was used in case of mixed chromatograms.

### **Conclusions**

There were 40 PCR-positive specimens (80 % of all specimens), 32 specimens were able to analyze only with PCR-DGGE. Ten bands (20 % of all bands) exhibited mixed nature, so that 8 specimens were identified by the combination of PCR-DGGE and RipSeq Mixed. The combination of established PCR-DGGE method and RipSeq Mixed analysis can eliminate failures of both approaches. More than 3 bacteria in a specimen can be detected and mixed chromatograms can be separated.

## **SOIL METHANOTROPHIC COMMUNITIES IN AN ALPINE WETLAND OF THE TIBETAN PLATEAU**

A. Ma<sup>1</sup>, G. Zhuang<sup>1</sup>, M. Cui<sup>1</sup>, H. Qi<sup>1</sup>, X. Zhuang<sup>1</sup>

<sup>1</sup>Key Laboratory of Environmental Biotechnology, Research Center for Eco-Environmental Sciences Chinese Academy of Sciences, Beijing, China

### **Background**

Methane (CH<sub>4</sub>) plays an important role in global warming and has been responsible for approximately 20% of the Earth's warming since the pre-industrial period. However, most CH<sub>4</sub> is consumed by methanotrophs before its emission into the atmosphere.

### **Objectives**

To understand the methane oxidizers in wetlands, the largest source habitat of atmospheric CH<sub>4</sub>.

### **Methods**

We used quantitative qPCR and functional gene-targeted 454 pyrosequencing to elucidate the abundance and diversity of aerobic and anaerobic (N-DAMO) methane oxidizers in the Zoige Wetland, which is located on the Tibetan Plateau and is the largest alpine wetland in the world.

### **Conclusions**

Our results demonstrated that type I methanotrophs were the primary aerobic methanotrophs, and *Methylobacter* comprised approximately 50% of the community. Type II methanotrophs, represented by the genus *Methylocystis*, were also detected, and the presence of N-DAMO bacteria in the Zoige Wetland was confirmed by the quantification and pyrosequencing analyses of N-DAMO 16S rRNA and *pmoA* genes. Furthermore, aerobic *pmoA* gene ranged from 10<sup>7</sup> to 10<sup>8</sup> copies•g<sup>-1</sup> of fresh soil, and the 16S rRNA gene of the NC10 phylum ranged between 10<sup>4</sup> and 10<sup>5</sup> copies•g<sup>-1</sup> of fresh soil. The results suggest that the aerobic and anaerobic methane-oxidizing communities together affect CH<sub>4</sub> cycle at the Zoige Wetland.

## **TRACKING RELATIONS AMONG BACTERIAL AND PROTOZOAN COMMUNITIES IN WASTEWATER TREATMENT PLANTS**

M. Martins Neto<sup>1</sup>, S. Chaves<sup>2</sup>, A. Nicolau<sup>1</sup>

<sup>1</sup>*University of Minho, Centre of Biological Engineering (CEB), Braga, Portugal*

<sup>2</sup>*University of Lisbon Faculty of Sciences,  
Biosystems and Integrative Sciences Institute (BioISI), Lisboa, Portugal*

### **Background**

Understanding the interactions between prokaryotic and eukaryotic populations in complex environments can be challenging. Particularly, there is a recognized difficulty in establishing how the interactions between the bacterial and the protozoan populations can affect the performance of wastewater treatment plants (WWTP).

### **Objectives**

In order to determine the relationships between microbial communities (protozoa, metazoa and filamentous bacteria) and abiotic parameters (physical-chemical and operational), thirty seven WWTP with activated sludge process were studied in Portugal, during two years, in a trimestral sampling strategy.

### **Methods**

Samples were collected to enable a molecular characterization of the microbiota. In order to ensure the diversity of microorganisms, 100 samples were selected based on their geographic localization and time-spaced to track relationships within bacteria and protozoa. A 16S rRNA gene PCR-DGGE approach was carried out for bacterial community fingerprinting. The resulting profiles were analysed together with the results obtained from the survey of the protozoa populations. Finally, the study of the correlations between the physical-chemical and operational parameters and the microbial communities was also investigated.

### **Conclusions**

The study of these interactions constitutes a strategy for the understanding of how the different metabolic groups of prokaryotic and protozoa are affected by the relations between this populations, allowing a better prediction of the overall community dynamics. This will allow setting the conditions that better contribute to improve the wastewater treatment while increasing the knowledge of overall communities networking in complex environments.

#### **INTRA-AMNIOTIC AND VAGINAL MICROBIOMES AT THE END OF PREGNANCY**

G.L. Mendz<sup>1</sup>, J.A. Quinlivan<sup>2</sup>, N.O. Kaakoush<sup>3</sup>

<sup>1</sup>*School of Medicine Sydney, The University of Notre Dame Australia, Darlinghurst New South Wales, Australia*

<sup>2</sup>*Institute for Health Research, The University of Notre Dame Australia, Fremantle Western Australia, Australia*

<sup>3</sup>*School of Biotechnology and Biomolecular Sciences, The University of New South Wales, Randwick New South Wales, Australia*

#### **Background**

The microbiota of the genital tract of *pregnant women* remains to be elucidated. Recent studies of the bacterial populations in different groups of pregnant women have yielded considerable amount of information on their bacterial communities. However, few comparisons have been performed between the vaginal and intra-amniotic microbiomes of individual women, and of women of different racial backgrounds.

#### **Objectives**

To investigate the compositions of the vaginal and intra-amniotic bacterial populations in late pregnancy of women from different racial backgrounds, and to compare the compositions of their genital microbiomes.

#### **Methods**

Vaginal and intra-amniotic swabs were obtained from 90 women at delivery by Caesarean section. Participants were administered a questionnaire including demographic and pregnancy data. The identity of the taxa present was determined by ultrafast sequencing of the V3V5 regions of the 16S rDNA gene of samples. Species diversity and richness, and Shannon's diversity analyses were performed on the sequence data of each woman. SIMPER analysis showed the contribution of each species to the vaginal and intra-amniotic microbiomes. PERMANOVA and PERDISP analyses showed that both genital microbiomes depend on racial background.

#### **Conclusions**

At variance with commonly held assumptions, the analyses identified in the intra-amniotic cavity of the women in the study rich and diverse bacterial populations that were significantly different to the vaginal populations. The results suggested that the intra-amniotic microbial profile remains quite stable independently of the variability of the vaginal microbial profile. The outcomes of this study have potentially important implications for the management of urogenital infections during pregnancy.

**METABOLIC TRANSFORMATIONS ENHANCES PSEUDOMONAS AERUGINOSA GROWTH ACTIVITY DURING INTERACTION WITH STAPHYLOCOCCUS AUREUS**

C.F. Michelsen<sup>1</sup>, S. Dyhrberg<sup>1</sup>, M.S. Bojer<sup>2</sup>, H. Ingmer<sup>2</sup>, P.C. Dorrestein<sup>3</sup>, L. Jelsbak<sup>1</sup>

<sup>1</sup>Systems Biology, Technical University of Denmark, Kgs. Lyngby, Denmark

<sup>2</sup>Department of Veterinary Disease Biology Food Safety and Zoonoses, University of Copenhagen, Frederiksberg C, Denmark

<sup>3</sup>Departments of Pharmacology and Chemistry and Biochemistry. Skaggs School of Pharmacy and Pharmaceutical Sciences, University of California at San Diego, La Jolla, USA

**Background**

Interactions among members of polymicrobial infections can result in altered pathogen behaviours such as enhanced virulence, biofilm formation or antibiotic tolerance, which may influence the disease phenotype and clinical outcome of the infection. *Pseudomonas aeruginosa* and *Staphylococcus aureus* are important opportunistic human pathogens and are both part of the polymicrobial infection communities in human hosts. Cell-cell communication can play a major role in the interaction behaviors between these bacteria, which subsequently can affect the physiology of the individual strains. However, the extent to which evolutionary processes may remodel interspecies interactions and bacterial physiology during the course of infection and therapy is currently not understood.

**Objectives**

Therefore, the aim of this study was to analyze *in vitro* interactions between *S. aureus* and a human host adapted *P. aeruginosa* strain from a dominant lineage, DK2, that have evolved through decades of growth in chronically infected patients.

**Methods**

By using a combination of *in vitro* agar assays, molecular genetics and MALDI-TOF imaging mass spectrometry we demonstrate that DK2 – in contrast to other *P. aeruginosa* strains - show a commensal-like interaction with *S. aureus* during *in vitro* co-culturing, where the growth activity of *P. aeruginosa* was increased in the presence of *S. aureus*. The commensal interaction was observed both under aerobic and anaerobic conditions as well as during growth on artificial CF sputum medium, however was abolished with *S. aureus* strains mutated in the *agr* quorum sensing system.

**Conclusions**

Our results suggest that metabolic transformations during interaction with *S. aureus* enhance the growth activity of *P. aeruginosa*.

## **OCCURRENCE AND ACTIVITY OF METHANOGENIC ARCHAEA IN AGRICULTURAL BIOGAS PLANTS**

B. Munk<sup>1</sup>, M. Lebuhn<sup>1</sup>, G.M. Gubit<sup>2</sup>

<sup>1</sup>*Department for Quality Assurance and Analytics,  
Bavarian State Research Center for Agriculture, Freising, Germany*

<sup>2</sup>*Institute of Environmental Biotechnology,  
University of Natural Resources and Life Sciences, Tulln, Austria*

### **Background**

Anaerobic digestion of organic substrates is a complex process which is accomplished by the cooperation of different microorganisms. The last part of the biogas process, the methanogenesis, is mostly the bottle neck of the whole process and is still not completely understood. Recently, molecular analyses of the microbial populations shed light on the microbiological 'black box', but on DNA-level, the whole population consisting of dead and inactive cells is analyzed

### **Objectives**

In this study, biogas plants were analyzed to investigate which fractions of the methanogenic community are transcriptionally active under different process conditions.

### **Methods**

Different lab- and full-scale biogas reactors with different substrate mixes and process conditions were analyzed for the community composition of methanogens on DNA- and mRNA-level. After DNA- and RNA-extraction, (RT-)PCR-cloning targeting the *mcrA/mrtA* gene coding for methyl-coenzyme M-reductase was conducted. Sequences were checked for chimeras, aligned and a phylogenetic tree was constructed.

### **Conclusions**

Hydrogenotrophic methanogens dominated in the investigated agricultural biogas plants, and acetoclasts were only present at high retention times. In well running systems only small differences were seen between the whole (DNA) and active (cDNA) methanogenic communities, and certain *Methanosarcinaceae* and *Methanobacteriaceae* dominated. During process disturbances, the active community mostly differed considerably from the whole community, and certain

*Methanobacteriaceae* took over the main transcriptional activity, not necessarily with productivity loss. A small part of the present methanogens obviously can take over the main part of the activity. The community should thus be analyzed on cDNA level in order to analyze the active part of the community reliably.

<sup>2</sup>*Department of HIV Care Laboratories,  
Nnamdi Azikiwe University Teaching Hospital Nnewi, Nnewi, Nigeria*

<sup>3</sup>*Department of Pediatrics, Anambra State University Teaching Hospital Amaku,  
Awka, Nigeria*

<sup>4</sup>*Department of Community Medicine,  
College of Health Sciences Nnamdi Azikiwe University, Awka, Nigeria*

### **Background**

Hospital-acquired infections (HAIs) are constituting major threat to hospitalization world-over. They occur in several different patient groups, especially patients on ventilators in intensive care unit where the rate of the pneumonia may be as high as 3% per day

### **Objectives**

This study was undertaken to unveil the burden of HAI in South-East, Nigeria.

### **Methods**

Structured questionnaires totaling 660 were administered personally to healthcare workers consisting of 96

doctors, 170 nurses, 24 pharmacists and 40 medical laboratory scientists from randomly selected government

hospitals and 90 doctors, 180 nurses, 30 pharmacists and 30 medical laboratory scientists from randomly selected private hospitals. Study was carried out between April and July 2013

The study shows that the prevalence of nosocomial infection in the hospitals surveyed is in the following

descending order: urinary tract infection (34.9%), *Staphylococcus aureus* (31.0%), Gastroenteritis (27.1%), Hospital acquired pneumonia (20.3%), *Candida albicans/Aspergillus spp* (10.8%), *Pseudomonas aeruginosa* (10.5%), Tuberculosis (9.0%), *Clostridium difficile* (3.9%), ventilator associated pneumonia (3.6%), Methicillin and vancomycin resistant bacteria (1.5%). The study also showed that the frequency of occurrence of HAP is higher in government than private hospitals. This can be attributed to the higher population of patients leading to overcrowding. The modes of transmission of hospital acquired pneumonia was observed to follow this order airborne > contact with blood and body fluids > contaminated instruments > contaminated hands > needle sticks.

### **Conclusions**

The prevalence of HAI in South-east, Nigeria is high. Efforts are needed to reduce the incidence, improve the quality of life of patients and healthcare workers and

improve healthcare delivery.

## **TRACKING MICROBIAL COMMUNITY DYNAMICS IN ENGINEERED AQUATIC SYSTEMS THROUGH FLOW CYTOMETRIC FINGERPRINTING**

R. Props<sup>1</sup>, P. Monsieurs<sup>2</sup>, N. Leys<sup>2</sup>, N. Boon<sup>1</sup>

<sup>1</sup>*Laboratory of Microbial Ecology and Technology (LabMET), Ghent University, Ghent, Belgium*

<sup>2</sup>*Microbiology research unit, Belgian Nuclear Research Centre (SCK•CEN), Mol, Belgium*

### **Background**

Characterizing and monitoring **the dynamics of microbial communities** has become an important research field in microbial ecology. Yet conventional microbial (e.g. heterotrophic plate counts) and molecular (e.g. Denaturing Gradient Gel Electrophoresis) workflows are time consuming and laborious.

### **Objectives**

Here, we applied **a novel statistical pipeline** on **flow cytometry** data in order to perform **rapid high-resolution and objective monitoring** of the microbial community dynamics in an oligotrophic **engineered aquatic system**. The obtained results were then related to the imposed operational conditions (pH, temperature, conductivity).

### **Methods**

A full-scale engineered, oligotrophic **cooling water system** operating on a nuclear test reactor was used as model system. This system operated under 3 week cycles and was monitored throughout two full cycles by **flow cytometry** and **on-line physicochemical sensors**. Aside from generating phenotypic community fingerprints, flow cytometric analysis also allowed the assessment of **total cell counts, nucleic acid content and cell viability**. Additionally, the exact microbial community throughout the cycles was determined with 16S rRNA amplicon sequencing

### **Conclusions**

Community fingerprinting indicated **a highly dynamic community shift** during the operation of the cooling water system. Five distinct phenotypic communities related to start-up, operational periods and inactivity of the reactor were identified. Conductivity and temperature were the predominant physicochemical factors but only partially explained the observed community shifts. The cooling water microbial community further showed an **oscillating pattern in cell concentrations and nucleic acid content** on both weekly and daily scale. The output of this phenotypic “fingerprint” approach was validated using **high-throughput 16S rRNA amplicon sequencing**.

<sup>2</sup>General and Applied Microbiology, Sofia University "St. Kl. Ohridsky", Sofia, Bulgaria

<sup>3</sup>Biogeochemistry, Institute of Radiochemistry Helmholtz Zentrum Dresden-Rossendorf, Dresden, Germany

<sup>4</sup>Biochemical Pharmacology and Molecular Design, Institute of Molecular Biology - Bulgarian Academy of Sciences, Sofia, Bulgaria

### **Background**

Pb-Zn smelter - KCM is the largest enterprise in the Balkan Peninsula producing lead, zinc and precious metals.

### **Objectives**

To assess bacterial diversity in heavy metal polluted soils *via* molecular and cultivation-based techniques.

### **Methods**

16S rDNA approach, as well as cultivation-based techniques were applied.

### **Conclusions**

Molecular analysis showed that microbial community in the studied samples consisted in different extent of *Proteobacteria* (a, b, g and d), *Actinobacteria*, *Holophaga/Acidobacteria*, AD1, *Cytophaga/Flavobacterium/Bacteroides*, *Cytophaga*, BD and novel bacteria. In the highly polluted soil sample - KCM 3 g-proteobacteria were not detected. Cultivation-based analysis showed presence of heterotrophic aerobs, heterophic anaerobs, sporeforming bacteria, denitrifying bacteria, amonifying bacteria, nitrifying bacteria, Fe(II)- oxidizing bacteria, Mn(II) oxidizing bacteria, Fe(III) redicing bacteria, Mn(IV) reducing bacteria, colourless sulphur bacteria, cellulose degradating bacteria, oligocarbophiles, metal-leaching bacteria *Acidithiobacillus thiooxidans*, *Acidithiobacillus ferrooxidans*, *Acidithiobacillus denitrificans*,

*Acidithiobacillus thioautotrophicus* except fungi and actinomycetes. Both analyses revealed that the microbial communities in the polluted area were strongly affected.

**INFLUENCE OF VERY EARLY EXPOSURE TO CEFUROXIME VIA THE MOTHER ON GUT MICROBIOTA COMPOSITION IN TERM BABIES BORN BY CAESAREAN SECTION**

S. Shamzir Kamal<sup>1</sup>, N. Hyldig<sup>2</sup>, L. Krych<sup>1</sup>, G. Greisen<sup>3</sup>, G. Zachariassen<sup>4</sup>,  
D. S. Nielsen<sup>1</sup>

<sup>1</sup>Department of Food Science, University of Copenhagen, Frederiksberg C, Denmark

<sup>2</sup>Department of Gynaecology and Obstetrics, Odense University Hospital, Odense, Denmark

<sup>3</sup>Department of Neonatology, Rigshospitalet, Copenhagen, Denmark

<sup>4</sup>Institute of Clinical Research, Odense University Hospital, Odense, Denmark

**Background**

Cefuroxime is an antibiotic effective against a wide range of Gram negative and Gram positive bacteria. It is standard procedure to give the mother a single prophylactic dose (1500 mg) of cefuroxime in relation to caesarean section (CS). If the antibiotic is given before the umbilical cord is cut the antibiotic will pass from the mother to the infant. However, the effect of this very early exposure to cefuroxime on infant gut microbiota (GM) colonization is still not known.

**Objectives**

To investigate if very early exposure to cefuroxime in CS born infants influences GM colonization.

**Methods**

42 pregnant women (BMI<30) scheduled for elective CS were recruited at Odense University Hospital, Denmark. Two mothers were expecting twins meaning that 44 infants were included in the study. The mothers were randomly assigned to either receiving cefuroxime before skin incision or immediately after the umbilical cord were cut. Faecal samples were collected from all infants 10 days after birth and GM composition determined by MiSeq-based tag-encoded 16S rRNA gene targeted high throughput amplicon sequencing.

**Conclusions**

The GM of both groups were dominated by the genera *Bifidobacterium*, *Clostridium* (relative abundance of both genera ~5-10%), *Veillonella* (~25-30%) and family Enterobacteriaceae (~25-30%). Testing with analysis of similarity (ANOSIM) on both unweighted ( $p=0.872$ ,  $R=-0.0401$ ) and weighted ( $p=0.140$ ,  $R=0.0317$ ) uniFrac distance matrices analysis revealed no major differences between the 2 groups. In conclusion, early and short exposure to cefuroxime does not have major effects on infant GM colonization.

## FEMS-2092

#### QUANTITATIVE CHANGES OF CLOSTRIDIUM SP. IN HUMAN INTESTINAL TRACT OF DIFFERENT AGE GROUPS

J. Stsepetova<sup>1</sup>, N. Sebnova<sup>1</sup>, A. Larionova<sup>2</sup>, T. Voor<sup>2</sup>, T. Roop<sup>1</sup>, M. Mikelsaar<sup>1</sup>, R. Mandar<sup>1</sup>, E. Sepp<sup>1</sup>

<sup>1</sup>Department of Microbiology, University of Tartu, Tartu, Estonia

<sup>2</sup>Children's Clinic, Tartu University Hospital, Tartu, Estonia

#### Background

Characterization of changes in gut microbiota during life-time is the first step in elucidating its role in health and disease. Bacteria belonging to the *Clostridium* sp. both commensal and pathogenic are highly abundant in the human gastrointestinal tract. However, during life the abundance of different predominant *Clostridium* species of healthy persons is not well studied.

**The aim** of the study was to assess the bacterial counts in *Clostridium* groups of intestinal microbiota of healthy humans within different life cycles.

#### Objectives

The study group comprised healthy infants (17male/8female; 11.9±0.6 month), children (13m/12f; 5.3±0.2 year-old), adults (4m/21f; 48.2±6.6 year-old) and elderly (9m/14f; 72.9±5.0 year-old).

#### Methods

DNA from fecal samples was isolated by using QIAamp DNA stool mini kit (Qiagen). The counts (plasmid copy number/g feces) were detected by real-time PCR with specific primers.

#### Conclusions

Four dominant *Clostridium* groups (*C.leptum*, *C.perfringens*, *C.coccoides* and *C.difficile*) were detected. Infants were more colonized with *C.perfringens* group bacteria in comparison to children, adults and elderly ( $p<0.001$ , for all respectively). Children were more colonised with *C.coccoides* group bacteria in comparison to elderly ( $p=0.005$ ). The counts of *C. leptum* group bacteria were highest in adults than in elderly and infants ( $p<0.001$ , both respectively). *C.difficile* prevailed in elderly and infants than in adults (10/23 (43.4%), 7/25 (28%) vs. 0/25 (0%),  $p<0.001$ ,  $p=0.005$ ; respectively).

Our study confirms that the quantitative composition of human intestinal *Clostridium* groups changes during life differentially. This data may be used for comparable analysis of the gut microbial composition between healthy persons and persons with particular disorders in different age groups.

**MICROBIOLOGICAL COMMUNITIES OF THE WATER OF GELLÉRT BATH  
(BUDAPEST, HUNGARY) STUDIED BY CLASSICAL AND SPECIAL  
CULTIVATION TECHNIQUES**

E. Tóth<sup>1</sup>, S. Szuróczy<sup>1</sup>, Z.S. Kéki<sup>1</sup>, M. Vargha<sup>2</sup>, K. Márialigeti<sup>1</sup>

<sup>1</sup>Department of Microbiology, Eötvös Loránd University, Budapest, Hungary

<sup>2</sup>Department of Water Hygiene, National Institute for Environmental Health, Budapest, Hungary

**Background**

Thermal baths are unique water environments combining a wide variety of natural and anthropogenic ecological factors. There is limited information on the microbiology of thermal baths in their complexity, tracking community shifts from the thermal wells to the pools.

**Objectives**

In the present study the “normal” microbial community of the well and the pool water in Gellért bath was studied in detail.

**Methods**

To isolate bacteria 10% R2A and minimal synthetic media (with „bath water”) with agar-agar and Gelrite were used after prolonged incubation time, moreover polyethylene blocks covered with media were also applied. Strains were identified by sequencing their 16S rRNA gene after grouping them by ARDRA.

**Conclusions**

On each applied media and from each sample the dominance of  $\alpha$ -Proteobacteria was characteristic though their diversity differed among samples. The largest groups in the pool water belonged to the *Tistrella* and *Chelatococcus* genera. The most dominant member in the well water was a new taxon, its similarity to *Hartmannibacter diasotrophicus* as closest relative was 93.62%. From each sample novel species could be isolated belonging to genera *Nocardioides*, *Rhizobium* and *Brevundimonas*. *Deinococcus* and low G+C Gram positives appeared only in the pool water. In order to cultivate novel taxa the best method was the combined use of minimal synthetic media, special cultivating techniques and increased incubation time.

**Microbial communities**

**CO-OCCURRENCE OF ATOPOBIUM VAGINAE AND GARDNERELLA VAGINALIS IN MALE URETHRA INDEPENDENTLY OF SEXUAL EXPOSURE**

A.R. Ugur<sup>1</sup>, I. Tuncer<sup>1</sup>, D. Findik<sup>1</sup>

<sup>1</sup>Medical Microbiology, Selcuk University, Konya, Turkey

**Background**

Bacterial vaginosis (BV) is the most common genital infection among women of reproductive age. It is characterized by a transition in vaginal microflora from *Lactobacilli* to anaerobic bacteria.

**Objectives**

Though BV has been strongly linked to sexual behaviour, an endless controversy over the sexual transmission of BV remains elusive. Hence, we aimed to investigate prevalence and co-occurrence of BV-associated bacteria in urethras of healthy adult men in accordance with sexual exposure by using species-specific PCR.

**Methods**

First-catch urine specimens, representative of urethral swabs, from 114 healthy male volunteers were collected between January-June 2014, in Konya/Turkey. DNA was extracted using QIAamp mini kit (Qiagen, Germany) from pellets of 15 mL of urine. *Lactobacillus crispatus*, *Lactobacillus jensenii*, *Lactobacillus gasseri*, *Lactobacillus iners*, *Gardnerella vaginalis*, *Atopobium vaginae*, *Peptoniphilus* spp., BVAB1, BVAB2, BVAB3, *Megasphaera* type I, and *Prevotella* spp. were investigated by species-specific PCR assay.

**Conclusions**

Of 114 participants, 49 were sexually-unexperienced, and 65 were sexually-experienced, and all were circumcised. The most common species were *Peptoniphilus* spp. (53.5 %), *L. iners* (50.8 %), *G. vaginalis* (50.8 %), and *A. vaginae* (20.1 %). There was no significant relation between any BV-associated bacterium and sexual exposure. The only significant difference was in the co-occurrence of *A. vaginae* and *G. vaginalis* ( $p=0.025$ ) in the male urethra independently of sexual exposure. This result was compatible with similar reports studied on females. Since both *A. vaginae* and *G. vaginalis* are dedicated as key microorganisms in BV pathogenesis, more comprehensive studies on male counterparts are warranted.

#### **VALIDATION OF THE INTELLICAP® SYSTEM AS A TOOL TO STUDY CHANGES IN THE SMALL INTESTINAL MICROBIOTA IN A DIETARY INTERVENTION STUDY**

E. van Hoffen<sup>1</sup>, D. Esser<sup>2</sup>, M. Kleerebezem<sup>1</sup>, A. Kardinaal<sup>1</sup>, C. Wanke<sup>3</sup>, S. Tibosch<sup>3</sup>, G. Hooiveld<sup>2</sup>, H. Timmerman<sup>1</sup>

<sup>1</sup>Health, NIZO food research, Ede, Netherlands

<sup>2</sup>Nutrition Metabolism & Genomics Group Div. Human Nutrition, Wageningen University, Wageningen, Netherlands

<sup>3</sup>Personalized Drug Delivery Group, Medimetrics Personalized Drug Delivery BV, Eindhoven, Netherlands

#### **Background**

The gut microbiota is involved in regulation of host metabolic and immune pathways, and is an important target for dietary interventions. Human microbiota studies are mainly based on the analysis of fecal samples. The microbiota in the small intestine differs substantially from the fecal microbial community, but is at least as relevant for human health. Nevertheless, this ecosystem has barely been studied due to the invasive sampling procedures. The IntelliCap® system is an electronic medical device for the site-specific delivery of drugs in the gastrointestinal tract. The IntelliCap® system has been adapted to aspirate liquid from its environment, and may thereby offer a minimally-invasive tool for sampling from the human small intestinal tract.

#### **Objectives**

To explore whether the IntelliCap® system can be used as a tool to study the human small intestinal microbiota composition.

#### **Methods**

A randomized cross-over controlled dietary intervention trial in 10 healthy male volunteers will be performed in January 2015. The study is approved by the Ethics Committee and subjects signed informed consent. Two diets are used: a three-day high-protein versus high-carbohydrate diet, each preceded by a washout diet. These diets aim to target microbiota with different fermentation requirements. The IntelliCap® capsule is administered after both intervention periods to collect a distal small-bowel sample. Fecal samples are collected from the same individuals. Microbiota composition is analyzed by sequencing using Illumina technology and dedicated bioinformatics.

## **Conclusions**

The IntelliCap® system may be applied to generate important new insights into the role of the human small intestinal microbiota in health and disease.

## **SPECIES DISTRIBUTION OF NON TUBERCULOSIS MYCOBACTERIA ISOLATES FROM NORTH OF IRAN**

S. Zaker Bostanabad<sup>1</sup>, S. Falsafi<sup>2</sup>, A. Hashemi-Shahraki<sup>3</sup>

<sup>1</sup>Biology&Microbiology, Islamic Azad University Parand branch, Tehran, Iran

<sup>2</sup>Biology&Microbiology, Islamic Azad University Resrach and Science branch, Tehran, Iran

<sup>3</sup>Biology&Microbiology, Pasteur Institute of Iran Epidemiology Department, Tehran, Iran

### **Background**

Nontuberculous mycobacteria (NTM) differ from tuberculous mycobacteria as most of them are ubiquitous and saprophytic. A few are considered to have the potential to infect humans. The immunological status of a person determines the advance of disease. On the other hand among environmental factors, water plays the main roles as a resource of contamination in transferring this group of microorganisms to human.

### **Objectives**

The aim of this study is to identify and isolate NTM in the different region of Iran surface water.

### **Methods**

62 water samples were collected from different regions of Northern Iran. Cetyl pyridinium chloride (cpc) 0.01% was used to decontaminate the water samples. After enrichment using filtration, all samples were incubated on Lowenstein-Jensen (LJ) medium at temperatures of 30 and 37 °C. Classical culture, biochemical and enzymatic methods are described for the identification of mycobacteria. *hsp65* gene has more variability in its sequences, compared to the some more conserved genes in NTM, for identification of mycobacteria to species level.

### **Conclusions**

There were different *hsp65* gene PCR-RFLP profiles produced by digestion with *Bst*ElI and *Hae*III. Dominant isolates were *M. fortuitum*. Other isolates of *Mycobacteria* were differentiated using *hsp65* genes PCR-RFLP. This study indicates that notable percentage of water sources are contaminated with mycobacterium species. The exposure of immuno-compromised individuals to these sources can have crucial consequences. Interestingly the prevalence of mycobacterium species differs in diverse geographical areas.

## **ENHANCEMENTS IN DNA-BASED DETECTION OF RARE SPECIES OF BACTERIAL COMMUNITIES BY PRETREATMENT USING GERMICIDAL ALKALINE CHEMICALS**

Y. Zo<sup>1</sup>, J.N. Kim<sup>1</sup>, M.J. Kim<sup>1</sup>

<sup>1</sup>*Biology, Kyungsung University, Busan, Korea*

### **Background**

In natural bacterial communities, the number of species existing at a low density levels is large and harbors the most of uncharted genetic information in nature. However, simple metagenomic sequencing methods can reveal those information for actively growing species unless a special method such as deep-sequencing or copy-number normalization is employed.

### **Objectives**

In this study, we aimed to develop a method increasing relative abundance of rare-species genomes while reducing that of predominant species. We hypothesized that treating community samples by a germicidal agent normalize copy number of genomes in metagenome samples.

### **Methods**

We treated soil and insect samples by alkalinizing chemicals including quicklime (CaO), NaOH, and KOH, which kills microbial cells in general. For each sample treated with different concentrations of alkalinizing chemicals, bacterial community was analyzed by t-RFLP and pyrosequencing of 16S rRNA gene, and by enumeration and identification of culturable bacteria.

### **Conclusions**

There were slight decrease of species richness in t-RFLP profile with stronger treatment (0-13% w/w CaO). However, overall diversity estimation (Shannon-Weaver diversity index) showed a steep increase at 3-5% CaO treatment. Chao1 estimates of richness for pyro-reads increased from 639±121 to 2,933±103 by optimal CaO treatment for soil samples. Rarefaction analysis on pyro-reads implied that richness of the untreated sample reached saturation while other richness values did not reach saturation. Shannon-Weaver diversity for pyro-reads increased from 1.8 to 6.7 by the optimal treatment. It could be concluded that the suggested treatments can increase

sensitivity of detecting rare species so that richness estimates increase more than five folds.

**Microbial persistence and chronic infections**

## **LONG-TERM SURVIVAL OF ENTEROCOCCUS FAECIUM OUTSIDE THE HUMAN HOST**

V. de Maat<sup>1</sup>, W. van Schaik<sup>1</sup>

<sup>1</sup>*Medical Microbiology, University Medical Centre Utrecht, Utrecht, Netherlands*

### **Background**

*Enterococcus faecium* is a Gram-positive commensal of the gut of human and animals. However, in the last few decades it has acquired resistance to several antibiotics and has become an important cause of nosocomial infections. *E. faecium* can survive outside the human host for an extended period of time, which increases its ability to spread throughout the hospital and cause outbreaks.

### **Objectives**

Our goal is to uncover the mechanisms used by *E. faecium* to survive outside the human host.

### **Methods**

Using prolonged batch culture in brain heart infusion broth (BHI) or incubation in nutrient-free phosphate buffered saline (PBS) we determined the capacity of two clinical *E. faecium* strains (E745 and Aus0004) to survive at 20°C and 37°C.

### **Conclusions**

We show that temperature has a critical role in the long-term survival of *E. faecium*. At 37°C viable counts in PBS drop by 90% after 2 – 3 days while at 20°C the viable counts remain stable for 5 days. During prolonged culture in BHI, viable counts decrease by 90% after 7 days, but at 20°C viable counts remain stable for 10 days. Our finding suggest that *E. faecium* has specific mechanisms to survive outside the human host for a prolonged period of time. Currently, high-throughput functional genomic experiments are being performed to identify the mechanisms which contribute to survival of *E. faecium* in nutrient-poor conditions at ambient temperature.

## **DEVELOPMENT OF A SIMPLE ANIMAL MODEL TO STUDY CHRONIC PSEUDOMONAS AERUGINOSA INFECTIONS**

M. Fauvar<sup>1</sup>, M. Callens<sup>2</sup>, S. Beullens<sup>1</sup>, J. Michiels<sup>1</sup>, E. Decaestecker<sup>2</sup>

<sup>1</sup>Centre of Microbial and Plant Genetics, KU Leuven, Leuven, Belgium

<sup>2</sup>Laboratory of Aquatic Biology, KU Leuven Kulak, Kortrijk, Belgium

### **Background**

Chronic infectious disease is increasingly recognized as a major public health threat. The development of novel, more effective antimicrobial therapies is of utmost importance. Antimicrobial drug discovery suffers from high attrition rates in later stages of drug development due to a lack of *in vivo* effectiveness of candidate drugs. Validation in an *in vivo* infection model early in the process is likely to remedy this problem. However, animal models that enable the *in vivo* study of chronic bacterial infections are typically complex and generally involve higher animals such as mice.

### **Objectives**

We sought to develop a simple animal model that would allow the study of a prolonged bacterial infection by a clinically relevant pathogen.

### **Methods**

We selected the opportunistic pathogen *Pseudomonas aeruginosa* and the crustacean host *Daphnia magna*. *D. magna* juveniles were infected with varying doses of a virulent strain of *P. aeruginosa*. While the highest infectious doses resulted in acute toxicity and complete mortality within 2 days after exposure, lower doses did not cause increased mortality compared to uninfected control populations up to 2 weeks after exposure. Infection with a *P. aeruginosa* strain expressing green and red fluorescent proteins allowed visualization of infection sites using fluorescence microscopy. Labeled bacteria were still readily identified 2 weeks after exposure, revealing a stable chronic infection.

### **Conclusions**

Together, our results strongly suggest that the simple *P. aeruginosa*-*D. magna* model is a suitable tool for studying chronic bacterial infections *in vivo* and support its further development for use in validation of candidate antimicrobials.

## **NEW INSIGHTS INTO PERSISTERS METABOLISM**

F. Goormaghtigh<sup>1</sup>, L. Van Melderen<sup>1</sup>

<sup>1</sup>*Département de Biologie Moléculaire, Université Libre de Bruxelles (ULB),  
Gosselies, Belgium*

### **Background**

Persistence is defined by a phenotypic switch occurring at low frequency ( $\approx 10^{-6}$ ) and generating a subpopulation tolerant to antibiotics. After removal of the antibiotic, persistent bacteria are able to regrow. Persistence is therefore thought to be responsible for chronic infections and could play a key role in the survival of biofilms to antimicrobials. Despite these observations, molecular mechanisms underlying persistence remain unclear.

### **Objectives**

The aim of this study is to shed light on the molecular mechanisms by which phenotypic variability is generated in bacteria, allowing them notably to switch from an antibiotic susceptible state to a persistent state.

### **Methods**

In a first approach, the main experimental parameters affecting *E. coli* persistence in our experimental conditions (aeration rate, overnight culture duration, growth medium, carbon source, ...) were identified. A standard and reproducible method for measuring persistence was then set up and validated. Using this method, we are currently investigating persisters genetics and metabolism. Approaches combining the use of deletion mutants, fluorescent transcriptional reporters and biosensors are used to determine which metabolic pathways are activated/shut down in persisters.

### **Conclusions**

Our data confirmed that persisters consist of highly heterogeneous populations. In addition, different classes of antibiotics appear to generate different persistent populations, characterized by the activation of distinct metabolic pathways and stress responses. This indicates that molecular mechanisms underlying persistence are not unique and a variety of mechanisms are involved. Population (FACS analyses) and

single-cell (time-lapse microscopy) behaviours are currently analysed to get further insights into persisters mechanisms diversity.

**Microbial persistence and chronic infections**

**DURING CHRONIC INFECTIONS SALMONELLA ACQUIRES MUTATIONS IN REGULATORS OF METABOLISM AND VIRULENCE GENE EXPRESSION**

L. Jelsbak<sup>1</sup>

<sup>1</sup>*Science Systems and Models, Roskilde University, Roskilde, Denmark*

**Background**

*Salmonella enterica* is responsible for diverse infections in mammals, including chronic infections. For *Salmonella enterica* serovar Typhi, the causative agent of typhoid fever, up to 6% of patients, will become life-long carriers.

**Objectives**

Despite the importance of chronic infections, the molecular mechanisms of chronic host association are poorly understood. The objectives of this study are to elucidate the mechanisms employed by *Salmonella* for establishment of chronic infections.

**Methods**

Mice were infected with low doses of *Salmonella*, and the development of chronic infections was followed over the course of the infection. After six weeks of infections mice were sacrificed and the livers and spleens were analyzed for the presence of *Salmonella*. Dominant clones of livers, spleens and fecal samples were whole genome sequenced to identify adaptive mutations.

**Conclusions**

Most clones had acquired one or two non-synonymous point mutations (single nucleotide polymorphism, SNP). Most SNP's were associated with metabolism and virulence regulation. For example, a dominant clone from a fecal sample had a SNP in *kdgR*, a repressor of genes of the Entner-Doudoroff pathway, indicating metabolic adaptation in this clone. Re-infection experiments revealed that the *kdgR*-SNP mutant exhibited rapid and superior colonization of the mouse intestines resulting in a super-shedder phenotype within 1-2 weeks post-infection. Furthermore, the KdgR-SNP regulator protein could not be induced leading to constitutive repression of its target genes, supporting metabolic remodeling in the *kdgR*-SNP mutant. In conclusion, during a short chronic infection, *Salmonella* adapts to its host by modifying the activity of central regulators of metabolism.

**Microbial persistence and chronic infections**

## **FEEDBACK BETWEEN MICROBIAL INTERACTIONS AND EVOLUTION IN CHRONIC CF INFECTIONS**

L. Jelsbak<sup>1</sup>

<sup>1</sup>DTU Systems Biology, Technical University of Denmark, Kgs. Lyngby, Denmark

### **Background**

Although many infections are assumed to be monoclonal it is becoming clear that interactions between bacterial pathogens and other microbes at the infection site may alter pathogen behaviour. We have limited understanding of the evolution of microbial interactions and the extent to which interactions constrain or promote evolution of the interacting partners during the course of infection.

### **Objectives**

Chronic airway infections in cystic fibrosis (CF) patients provide opportunities to study microbial evolution and its relation to microbial interactions. The CF airways are nearly always infected with a number of microorganisms, including *Pseudomonas aeruginosa*. CF infections are associated with genetic adaptation of *P. aeruginosa*, and to understand the adaptive mechanisms, we have focused on two transmissible *P. aeruginosa* lineages – DK1 and DK2 - that share a similar natural history: They both entered the Copenhagen CF Clinic more than 40 years ago, adapted in one or a few patients and subsequently spread to a large number of patients. Our aim is to uncover the genetic changes that determine the apparent dominance of these clones, and to investigate in which way microbial interactions shape the evolutionary pathways.

### **Methods**

The systematic collection of bacterial isolates from lung expectorates of CF patients at the Copenhagen CF Clinic since 1973 has made it possible to investigate within-host evolution of both lineages in relation to both inter- and intraspecies interactions.

### **Conclusions**

We show that the microbial CF community context impact evolution of the individual lineages, and that evolved changes within individual species can modify the behavior of the infection community

*<sup>8</sup>Psychiatry Clinic, T.C. Health Ministry Erenkoy Mental Health and Neurology Training and Research Hospital, ISTANBUL, Turkey*

**Background**

It's known that, in the occurrence of schizophrenia, genetic predisposition, neurodevelopmental disorders and environmental factors play role. It was suggested that synthesis of brain-derived neurotrophic factor (BDNF) and neurotrophin3 (NT3) were upregulated from monocyte/macrophages infected with Chlamydomphila pneumoniae, considered among environmental factors.

**Objectives**

In this study we aimed to show at the worldwide level, for the first time, the relation of C.pneumoniae infection, BDNF and NT3 levels .

**Methods**

In this crosssectional retrospective study 50 patients with shizophrenia and 35 healthy controls(HC) were included. The C.pneumoniae DNA was investigated by RT-PCR from PBMC and IgA, IgG, IgM were investigated by immunofluoresans in both

group's serum. BDNF and NT3 levels were determined by ELISA. Chi square student's t and Mann Whitney U tests were used for statistical analyses .

### **Conclusions**

A significant difference was found between PG and HC cases for chronic C. pneumoniae infection seropositivity ( $p < 0.05$ ). The mean serum BDNF and NT-3 levels were found to be significantly lower for PG members than for HC members ( $p < 0.001$ ). We couldn't detect any C. pneumoniae DNA in PBMC of 85 participants. In conclusion, although in HG, compared to HC, the presence of chronic C. pneumoniae infection was found remarkable high, BDNF and NT3 levels, were found significantly low in PG compared to HC, which is the first international study in the basis of C. pneumoniae, schizophrenia relation, and the detection of BDNF and NT3 levels, a conviction wasn't reached and we suggest that new studies, especially based on cohort and performed with large series including these three parameters supported by molecular methods are needed.

**MOLECULAR MECHANISM ANALYSIS OF PERSISTERS FORMATION WITH A CELL DIVISION MARKER**

Y. Kawai<sup>1</sup>, S. Miyagawa<sup>1</sup>, S. Okuda<sup>2</sup>, S. Matsumoto<sup>3</sup>, S. Tsuneda<sup>1</sup>

<sup>1</sup>*Department of Life Science and Medical Bioscience, Waseda University, Tokyo, Japan*

<sup>2</sup>*Graduate School of Medical and Dental Science, Niigata University, Niigata, Japan*

<sup>3</sup>*Center for Biofilm Engineering, Montana State University, MT, USA*

**Background**

Persisters are multidrug tolerant cells due to their suppression of cell division. When bacterial population is exposed to antibiotics, persisters could survive and cause for the recurrence of infections. Although molecular mechanisms of bacterial persistence to antibiotics have been studied, a crucial gene had not been identified. Since the mechanisms of persisters formation are redundant, analysis targeting a specific single gene is not appropriate for persister researches.

**Objectives**

The objective of our research is to develop a marker for persisters that enable to isolate persisters and to analyze an exhaustive gene expression.

**Methods**

To distinguish non-dividing cells from dividing cells, fluorescent protein YFP and CFP were fused at the both N and C terminals of FtsZ as a cell division marker. The fusion proteins emit CFP fluorescence in non-dividing cells, moreover they emit fluorescence resonance energy transfer (FRET) signal at Z-rings in dividing cells. This mechanism enables to visualize non-dividing cell and dividing cell. Non-dividing persisters were isolated using a cell sorter and their transcriptome was explored using a microarray.

**Conclusions**

The fusion FtsZ emitted FRET fluorescence at the Z-ring. Sorted cells in low FRET signal fraction exhibited about 50 times higher survival rate after exposure to antibiotics (ofloxacin) than cells in high FRET signal fraction. Hence, our method attained an objective. Transcriptome analysis suggested following three hypotheses; i) persisters take up energy by anaerobic respiration, ii) membrane protein is sensing changes of the environment, iii) clinical thread is not caused only by persistence, but also by secretion system.

**Microbial persistence and chronic infections**

**IN VITRO EVOLUTION OF PERSISTENCE BY CYCLIC TREATMENT WITH AMINOGLYCOSIDES IN PATHOGENIC ESCHERICHIA COLI AND SALMONELLA**

J.E. Michiels<sup>1</sup>, B. Van den Bergh<sup>1</sup>, P. Vandenboer<sup>1</sup>, N. Verstraeten<sup>1</sup>, M. Fauvart<sup>1</sup>, J. Michiels<sup>1</sup>

<sup>1</sup>Centre of Microbial and Plant Genetics, KU Leuven, Leuven, Belgium

**Background**

Bacteria can evade antibiotic eradication by forming transiently antibiotic-tolerant phenotypic variants, called persisters. Persistence is linked to the recurrent and chronic nature of many bacterial infections, but mechanisms underlying this phenomenon have mainly been investigated in non-pathogenic *Escherichia coli* lab strains.

**Objectives**

Infections by many Gram-negative pathogens are becoming increasingly difficult to treat due to resistance towards multiple antibiotics. Since aminoglycosides often retain activity against these strains, there is revived interest in their clinical use. We investigated the evolution of persister levels in uropathogenic *E. coli* and *Salmonella* under periodic aminoglycoside treatment.

**Methods**

Previously, a method for the experimental evolution of persistence by cyclic antibiotic treatment was optimized in our lab. Here, we apply this method to investigate the evolution of persister levels in uropathogenic *E. coli* UT189 and *S. enterica* Typhimurium SL1344.

**Conclusions**

Once daily, high dose aminoglycoside application rapidly selects for mutants with extremely high persister levels, while resistance levels (minimum inhibitory concentrations) remain unchanged. Likewise, mutants show increased persister levels in biofilms. Moreover, evolved uropathogenic *E. coli* mutants display cross-tolerance to fluoroquinolones, although high persister levels of *S. enterica* Typhimurium mutants seem antibiotic-specific. The dosing scheme of our *in vitro* experiments is roughly comparable to current clinical practice, underscoring the relevance of our findings. Future clinical evaluations of antibiotic dosing regimens

should include an assessment of persistence, as this could be an overlooked factor in failure of antibiotic therapy.

**Microbial persistence and chronic infections**

## **A SURVEY OF NASAL CARRIAGE RATE OF STAPHYLOCOCCUS AUREUS IN DIALYSIS PATIENTS**

M. Momen-Heravi<sup>1</sup>, Z. Chitsazian<sup>1</sup>

<sup>1</sup>*infectious disease, Kashan University of Medical Sciences, Kashan, Iran*

### **Background**

Staphylococcus aureus is the most common cause of cutaneous pyogenic infection. Some groups of individuals seem to be particularly prone to colonization with S.aureus. For example, patients undergoing chronic hemodialysis and users of illicit intravenous drugs

### **Objectives**

The purpose of this study was determination of nasal carriage rate of S.aureus in dialysis patients

### **Methods**

This survey was carried out in a descriptive analytic cross-sectional research in 2012. 71 patients of chronic renal failure were selected who had undergoing dialysis in dialysis ward of kashan. After obtaining consent form ,Specimens with swabs were performed from anterior nares nose of the patients .the questioners having demographic and related risk factors were filled through interviewing.anitimicrobial resistance S aureus of positive cases were determined by disk diffusion

### **Conclusions**

The patients were 41 females (53.2%) and 36 males (46.8%). The mean of age in patients was 48.43 years and the mean of duration of dialysis was about 23.54 months. 12 cases were nasal carriers of S.aureus (16.9%). There was no significant statistical correlation between sex,age, job, under lying disease and duration of dialysis and nasal carriage. The most resistance of S.aureus was seen to meticillin and the most sensitivity was to rifampin. Resitance to cefazolin ,cotrimoxazole 33.3,vancomycin 50% and cloxacillin 75%.there was no S aureus was fully sensitive to vancomycin.

Considering to 16.9% frequency of S aureus carriage among dialysis patients and 50% resistance to vancomycin ,periodic examination and proper treatment due to antibiogram results is recommended.

**DOES TONSILS AND ADENOID TISSUE PLAY A RESERVOIR ROLE FOR COLONIZATION OR INFECTION WITH HAEMOPHILUS INFLUENZAE IN PATIENTS WITH CHRONIC ADENOIDITIS OR CHRONIC TONSILITIS?**

Y. Nakipoglu<sup>1</sup>, G. Gunel<sup>1</sup>, D. Kanliada<sup>2</sup>, L. Aydemir<sup>2</sup>, N. Gurler<sup>1</sup>, B. Gurler<sup>1</sup>

<sup>1</sup>Medical Microbiology, Istanbul Faculty of Medicine, Istanbul, Turkey

<sup>2</sup>Ear Nose Throat (ENT), Istanbul Faculty of Medicine, Istanbul, Turkey

**Background**

*Haemophilus influenzae* is a commensal bacteria but can cause severe infections including meningitis, sepsis, bacteraemic pneumoniae, otitis media, sinusitis, and chronic bronchitis

**Objectives**

The present study was conducted to investigate the reservoir role of tonsils and adenoid tissue for colonization with *H.influenzae* bacteria in patients with chronic tonsillitis and adenoiditis and genotyping analysis of the strains isolated from both sites of the same patient

**Methods**

A total of 200 specimens (100 tonsils and 100 adenoid tissue) were taken from 100 chronic tonsillitis and adenoiditis patients who undergoing adenotonsilectomy. All samples were bacteriologically cultured and Pulsed field Gel electrophoresis (PFGE) method was applied for all *H.influenzae* isolates which revealed a high growth in tonsil and adenoid tissue.

**Conclusions**

**Results.** It was found that 82 out of 100 (82%) tonsils and 79 out of 100 (79%) adenoid tissue cultures a total of 161 samples were exhibited 274 bacteria from different bacterial species. *H.influenzae* strains were formed % 32 (87/274) of the total bacterial growth. A twenty eight isolates from each of tonsils and adenoid tissue of 28 patients (56 isolates) were analyzed by PFGE method which revealed that 52 out of 56 (92.85%) *H.influenzae* strains of 26 patients were similar whereas four strains of two patients were different.

**Conclusion.** The tonsils and adenoid tissue are playing a reservoir role not only for colonization with *H.influenzae* and other different bacterial species but each site is also a reservoir for others and vice versa. For our opinion *H.influenzae* strain could be a key for prevention of chronic tonsillitis and adenoiditis.

**Microbial persistence and chronic infections**

**MYCOBACTERIAL PERSISTENCE: USING MICROFLUIDICS AND SINGLE-CELL MICROSCOPY TO INVESTIGATE HOW MYCOBACTERIA SURVIVE ANTIBIOTIC EXPOSURE**

M. Priestman<sup>1</sup>, B.D. Robertson<sup>1</sup>

<sup>1</sup>Centre for Molecular Bacteriology & Infection (CMBI), Imperial College, London, United Kingdom

**Background**

Up to a third of the world's population is estimated to be infected with *Mycobacterium tuberculosis*, the causative agent of tuberculosis (TB). A significant ability of this pathogen is its capacity to adapt to and survive stress. This may in part be the reason why TB treatment requires such a lengthy time – at least 6 months of antibiotics. Both of these observations may result from a propensity for mycobacteria to form antibiotic tolerant persisters.

**Objectives**

We investigate how growth rate affects mycobacterial survival when exposed to antibiotics, with an initial assumption that growth arrest is a major mechanism promoting bacterial survival under these conditions.

**Methods**

A microfluidic platform was used that allows observation of single-cells of *M. smegmatis* by widefield microscopy, with constant flow of defined medium, and rapid switching between different conditions. The drug rifampicin was used to dissect persister formation due to its bactericidal properties, as well as its clinical relevance in TB treatment. Nutrient limitation was used to determine how this affects persister formation.

**Conclusions**

Growth rate of individual cells prior to rifampicin exposure appears to have no impact on their ultimate survival, however growth arrest is clearly observed during antibiotic exposure in all cells. Nitrogen limitation and starvation appear to significantly decrease survival, whilst carbon limitation appears to have little effect. This work, though preliminary, may enhance our understanding of how persisters form in mycobacteria, and help in the design of novel intervention strategies to combat tuberculosis.

**FREQUENCY OF ANTIBIOTIC APPLICATION DICTATES RAPID EVOLUTIONARY ADAPTATION OF BACTERIAL PERSISTENCE**

B. Van den Bergh<sup>1</sup>, J.E. Michiels<sup>1</sup>, T. Wenseleers<sup>2</sup>, L. De Meester<sup>3</sup>, K. Verstrepen<sup>4</sup>, N. Verstraeten<sup>1</sup>, M. Fauvart<sup>1</sup>, J. Michiels<sup>1</sup>

<sup>1</sup>Centre of Microbial and Plant Genetics, KU Leuven, Leuven, Belgium

<sup>2</sup>Laboratory of Socioecology and Social Evolution, KU Leuven, Leuven, Belgium

<sup>3</sup>Laboratory of Aquatic Ecology Evolution and Conservation, KU Leuven, Leuven, Belgium

<sup>4</sup>Laboratory for Systems Biology, VIB, Leuven, Belgium

**Background**

Microorganisms employ different strategies to cope with changing environments. Typically, a dedicated sensor perceives a specific environmental trigger and signals an adaptive response. However, if changes are rare and/or abrupt, maintenance and time lag of sensory systems become too costly. Consequently, bacteria evolved the capacity of switching stochastically between phenotypes to hedge their bets. Such a bet-hedging strategy based on a non-genetic switch between a sensitive growth state and an antibiotic-tolerant, non-growing persister stage, protects bacteria against eradication by antibiotics. Persistence causes antibiotic therapy failure and is therefore responsible for the chronic and sometimes incurable nature of infections.

**Objectives**

Little is known about the evolutionary forces that determine persister levels. We therefore aim to delineate the evolutionary dynamics of persistence. Furthermore, we want to explore the theoretically suggested and intuitively appealing correlation between the level of persistence and the frequency of antibiotic application.

**Methods**

We used experimental evolution in *Escherichia coli* to demonstrate rapid, reproducible and reversible changes in tolerance levels that optimize the population's fitness in function of the treatment frequency. Daily antibiotic attacks select for single-nucleotide changes that confer high persister levels (up to 100 %) and shorten persister lag phase. Persister levels decrease again in the absence of selective pressure. When time between antibiotic strikes increases, intermediate persister levels evolve that correlate with treatment frequency.

**Conclusions**

We show that persistence is an evolvable phenotype that quickly adapts to environmental dynamics, which may have important implications for developing optimal treatment strategies of chronic bacterial infections.

<sup>2</sup>Queensland Children's Medical Research Institute, The University of Queensland, Herston, Australia

<sup>3</sup>Department of Thoracic Medicine, The Prince Charles Hospital, Chermside, Australia

**Background**

Cystic Fibrosis (CF) is a genetic disorder that results in impaired mucociliary clearance of inhaled microorganisms. Over time, the airways of CF patients become colonised with different microorganisms, resulting in infections that cannot be eradicated. An uncommon pathogen of CF patients, but of rising significance, is *Burkholderia pseudomallei* (Bp). Bp is an opportunistic environmental pathogen that causes melioidosis, a potentially fatal disease that is endemic in most tropical regions, particularly northern Australia and Southeast Asia. Melioidosis is being increasingly described in CF patients returning from or living in melioidosis-endemic regions. Presentations of melioidosis in CF patients range from acute infection with rapid deterioration, to a chronic infection with slowly progressive deterioration in lung function.

**Objectives**

Unfortunately, the molecular basis for this chronic presentation remains entirely unknown.

**Methods**

To address this knowledge gap, we performed whole-genome sequencing on paired longitudinal Bp isolates from five Australian CF patients. To complement the genetic analysis, we have also performed stranded, deep sequencing of the transcriptome using Illumina RNA-seq. To best mimic the bacterial expression profiles in the CF lung, isolates were grown in an artificial sputum medium and RNA was extracted at late-log phase.

**Conclusions**

We will be reporting on the genomic and transcriptomic changes detected in the CF isolates, which have been shaped by within-host evolution. Similarly to common CF pathogens such as *P. aeruginosa*, we have observed a rise in multi-antibiotic resistance and changes to virulence factor expressions and metabolism.

**ANTIBIOTICS STRONGLY AFFECT COST AND BENEFIT OF COMPETENCE IN BACILLUS SUBTILIS**

M. Yueksei<sup>1</sup>, J. Power<sup>1</sup>, T. Volkmann<sup>1</sup>, B. Maier<sup>1</sup>

<sup>1</sup>Theoretical Physics/Biophysics, University of Cologne, Cologne, Germany

**Background**

*Bacillus subtilis* differentiates stochastically into the state of competence for transformation. Transformation is thought to speed up adaptive evolution in the presence of antibiotic stress.

**Objectives**

Here we address the question if the state of competence confers a strong benefit during episodic antibiotic treatment and acts as a persister state.

**Methods**

Using head-to-head competition experiments between strains with different rates of differentiation into the state of competence, we found that the cost of competence increases with the probability of differentiation. Competence was highly beneficial when competitors were treated episodically with antibiotics that inhibit cell wall synthesis, translation, transcription, or proton motive force. This benefit was independent of transformation. Time-kill kinetics in conjunction with single cell time lapse microscopy showed that the state of competence is a persister state. Addition of antibiotics did not increase the fraction of competent cells, indicating that competent *B. subtilis* are type II persisters. Finally, we tested whether the generation of phenotypic heterogeneity in terms of competence served as a bet-hedging strategy when *B. subtilis* was treated episodically with antibiotics. In competition experiments between strains with different probability of differentiating into the state of competence we found that populations that generate phenotypic heterogeneity minimize the cost of competence under benign conditions while increasing the probability of survival when challenged with antibiotics.

**Conclusions**

We conclude that *B. subtilis* uses a bet-hedging strategy for increasing its chance of survival when challenged with antibiotics by stochastically differentiating into the state of competence which acts as a persister state.

**Microbial persistence and chronic infections**

**QUANTITATIVE ANALYSES OF PHENOTYPIC STABILITY OF STAPHYLOCOCCUS AUREUS SMALL COLONY VARIANTS ISOLATED (SCV) FROM CYSTIC FIBROSES (CF) PATIENTS**

*I. Hasenleithner<sup>1</sup>, B. Foll<sup>1</sup>, L. Masoud-Landgraf<sup>1</sup>, A.J. Grisold<sup>1</sup>, C. Kittinger<sup>1</sup>,  
G. Zarfel<sup>1</sup>*

*<sup>1</sup>Institute of Hygiene Microbiology and Environmental Medicine,  
Medical University of Graz, Graz, Austria*

**Background**

Formation of small colony variants (SCV) of *Staphylococcus aureus* is a strategy (not only for *Staphylococcus aureus*) to overcome antibiotic treatment and to escape the immune system. This phenotype can persist for long time periods in patients with low pathogenic activity. One problematic feature of SCV is the ability to switch easily back to a more virulent phenotype.

**Objectives**

The aim of the study was to establish a test to quantify the ability of SCV's to switch back to a non SCV phenotype and to test several clinic isolates.

**Methods**

Five *Staphylococcus aureus* SCVs, isolated from five different patients with cystic fibrosis were tested. All SCV's were not able to grow in Mueller Hinton (MH)-broth. From each isolate 500 single colonies grown on Lysogeny Broth (LB)-Agar for 24 h showing SCV colony type were inoculated in 200µL MH broth for 24h. Growth in MH was confirmed by plating on MH agar plates and identification of *S. aureus* via MALDI-TOF analysis.

**Conclusions**

Four of the five SCV isolates showed stable phenotype with only 0-0.8% phenotype changes. In contrast one SCV changed the phenotype in 25.2%, which means at least one bacterial cell restored the ability to grow on/in MH media.

This test method is based only on one SCV characteristic and does not document if there is a total reoccurrence of the original wild type phenotype. Nevertheless it is an easy assay, and it will be a possibility to investigate the influence of different conditions on the stability of SCV's.

## **SCIENTIFIC EXHIBITIONS: THE MICROBIOLOGY FROM THE LAB TO THE STREET**

M. Orruño<sup>1</sup>, M. Soto<sup>2</sup>, I. Arana<sup>3</sup>

<sup>1</sup>*Inmunología Microbiología y Parasitología, Universidad del País Vasco UPV/EHU, Vitoria/Gasteiz, Spain*

<sup>2</sup>*Zoología y Biología Celular Animal, Universidad del País Vasco UPV/EHU, Leioa, Spain*

<sup>3</sup>*Inmunología Microbiología y Parasitología, Universidad del País Vasco UPV/EHU, Leioa, Spain*

### **Background**

In November, the University of the Basque Country (UPV/EHU) organized the 14th edition of the Science Week (ZientziaAstea). This annual event, aimed at audiences of all ages, tries to bring scientific concepts, methodologies and innovations to a non-specialist public by means of children's workshops, scientific shows, conferences and other activities. The microbiology has been present in this event from the first edition.

### **Objectives**

In ZientziaAstea, we aim to bring the public diverse aspects of microbiology, to clarify certain misconceptions and to show its importance in our daily lives.

### **Methods**

Every year, our Department's staff prepares materials and activities and attends the questions of school children and general public in a stand. Initially, the proposals consisted mainly in microbial cultures, photographs, diagrams and microscopic preparations. Year-to-year, proposals have become more complex, including models, videos, and posters with a common thread (hydrothermal vents, food, interactions) or hot topics (ebola). In the latest edition, we have incorporated the workshop *Microorganisms working* to refute the bad image of microorganisms and to highlight their benefits and their ecological and industrial importance.

### **Conclusions**

We have observed a good response for assistance and acceptance by the public in these activities, but we have also detected the need to renew the issues and approach. As consequence, for the 15th edition we are preparing the workshop *Small microbiology for small scientists* that, through games and activities, will try to introduce children the microbial world (the microbial diversity in a big drop of water or in our body, the bacterial growth, etc...).

**WORKING ON ACCESSIBILITY OF MICROBIOLOGY EDUCATION FOR DEAF COMMUNITY: DEVELOPMENT AND USE OF A NEW SCIENTIFIC GLOSSARY IN SIGN LANGUAGE**

I. Belda<sup>1</sup>, A. Alonso<sup>1</sup>, A. Portillo<sup>1</sup>, A. Caballero<sup>1</sup>, C. Martín-Arregui<sup>1</sup>, A. Santos<sup>1</sup>, D. Marquina<sup>1</sup>

<sup>1</sup>Microbiology III, Complutense University of Madrid, Madrid, Spain

**Background**

University should be an open and accessible environment to all people, where knowledge and opinion can be exchanged. Deaf community often finds scientific language as a hard barrier blocking their education. Knowing that most of Sign Languages are usually extremely colloquial, the development of an international scientific Sign language seems to be as useful as necessary.

**Objectives**

This work aims to develop a handy and rigorous Sign Language that allows to all Deaf community establish an independent university education and research avoiding the problems associated with continued use of interpreters.

**Methods**

We have created a sum of 320 signs for terms commonly used in science and related with Microbiology. These terms have been attributed to a sign, maintaining a logic in the use of Sign Language and a scientific adequacy. All the signs have been validated and used both by qualified interpreters and by deaf students from Complutense University of Madrid. All the terms have been included in a glossary and diffused firstly by using the Complutense University "Virtual Campus" and then on the web page of Spanish Society for Microbiology.

**Conclusions**

The main objective of this project has allowed us to develop teaching resources adapted to deaf students. The glossary has been applied to design dynamic accessible slides including explanations in Sign Language and illustrative multimedia tools making easier the educational process to deaf students in both, theoretical and practical lessons on Microbiology.

**ANTIBIOTIC RESISTANCE: DEFINING THE SCIENTIST'S RESPONSIBILITY.**

L. Bowater<sup>1</sup>

<sup>1</sup>*The Norwich Medical School, The University of East Anglia, Norwich,  
United Kingdom*

**Background**

Antibiotics transformed global health and the fields of scientific discovery. The use of antibiotic tools is ubiquitous but the rise of antibiotic resistance is threatening modern medicine. Scientists are asking manufacturers to stop selling antibiotics as growth promoters; new initiatives to stimulate antibiotic research; and a better educated public and clinicians to champion responsible use of antibiotics.

**Objectives**

The next generation of biologists and microbiologists are taught the mechanisms of antibiotic resistance in formal academic settings. They learn about the 'urgent need' for new antibiotics, from a teaching and scientific research community urging responsible use of antibiotics. Yet students attend laboratory-based practical classes relying heavily on antibiotics. Should the scientific community examine how learning opportunities encompassing antibiotics and antibiotic resistance are incorporated across university curricula to ensure we provide young scientists with consistent and synoptic information? Should future scientists be encouraged to use antibiotics more responsibly and sparingly in both educational and research settings?

## **Methods**

The roundtable discussion will debate whether we give conflicting messages to young scientists and will examine how learning opportunities encompassing antibiotics and antibiotic resistance questions are provided. Should we begin to practice what we preach and develop alternative practical classes where antibiotics and antibiotic resistance are not treated as disposable teaching tools?

## **Conclusions**

Self scrutiny of our own educational practices will give us a stronger voice when we ask society to use antibiotics more responsibly and may encourage development of new technologies offering similar benefits and functionality as current tool set that is based on antibiotic resistance.

#### **ACTIVITIES OF THE EDUCATION & COMMUNICATION DIVISION OF THE SPANISH SOCIETY FOR MICROBIOLOGY (D+D SEM): FOCUS ON YOUTH**

V.J. Cid<sup>1</sup>, I. Belda<sup>2</sup>, A. Ventosa<sup>3</sup>, M. Llagostera<sup>4</sup>

<sup>1</sup>*Dpto. de Microbiología II, Universidad Complutense de Madrid, Madrid, Spain*

<sup>2</sup>*Dpto. de Microbiología III, Universidad Complutense de Madrid, Madrid, Spain*

<sup>3</sup>*Dpto. de Microbiología, Universidad de Sevilla, Sevilla, Spain*

<sup>4</sup>*Dpto. de Microbiología, Universitat Autònoma de Barcelona, Barcelona, Spain*

#### **Background**

The Spanish Society for Microbiology (*Sociedad Española de Microbiología*, SEM; [www.semicrobiologia.org](http://www.semicrobiologia.org)) has 11 specialised Divisions. Among them, the most recently created and transversal is the Education and Communication Division (*Docencia y Difusión*, D+D SEM; [www.semicrobiologia.org/ddm](http://www.semicrobiologia.org/ddm)). It hosts 180 members committed to Education in Microbiology at several educational levels within Spain and to promote our Science to Spanish-speaking people worldwide via the internet and social networks.

#### **Objectives**

D+D SEM aims to cover different degrees of formation:

#### **Methods**

First, a work team establishes links with professionals at primary and secondary schools, offering assessment and support to Science teachers about microbiological subjects, and aiming to the content of official teaching modules and text books. D+D SEM has recently published a book of educative short stories about Microbiology aimed to children.

Second, D+D SEM promotes the elaboration and open exchange of materials and resources for Microbiology Education for University degrees, including videos, podcasts, games, blogs, interactive on-line tools, webpages and innovative approaches for Microbiology teaching. Remarkably, our Division organizes yearly workshops on “Initiation to Research in Microbiology”, in which 20 brilliant and motivated University students selected nationwide share with senior Microbiologists their passion for research.

Third, at the postgraduate level, young researchers can find support and information on Master degrees, training courses or job opportunities at the Group of Young Researchers ([sites.google.com/site/jovenesinvestigadoressem](http://sites.google.com/site/jovenesinvestigadoressem)), hosted by D+D SEM.

#### **Conclusions**

We seek to share experience and coordinate our effort with similar initiatives in other countries.

**WORKSHOPS ORGANISED BY STUDENTS FOR STUDENTS: AN ORIGINAL  
MULTIDISCIPLINARY APPROACH FOR TEACHING MICROBIOLOGY AND  
INFECTIOUS DISEASES.**

M. Eveillard<sup>1</sup>, M.L. Joly-Guillou<sup>1</sup>, E. Rineau<sup>2</sup>, I. Richard<sup>3</sup>, L. Dubé<sup>2</sup>

<sup>1</sup>*Microbiology, University of Angers, Angers, France*

<sup>2</sup>*Anaesthesiology, Angers teaching hospital, Angers, France*

<sup>3</sup>*Dean, University of Angers, Angers, France*

**Background**

During the last decades, efforts have been made for the development of innovative teaching in medical studies.

**Objectives**

To describe an Innovative Teaching Unit (ITU) implemented for the students being in the 4<sup>th</sup> year of medical studies in Angers University, France.

**Methods**

This ITU includes 20 original topics. Each year, each topic is attributed to 4 groups containing 4 students. After choosing an issue in the field of their topic, they have to organise and conduct a 3-hour workshop, to present a poster or an oral communication in a local congress, and to produce a written report. Each topic is supervised by two teachers from different medical specialties to ensure a multidisciplinary approach. The topic called 'Major sanitary crises' (MSC) was included in the ITU 4 years ago.

**Conclusions**

Two or three meetings between 2 teachers and students are necessary to prepare the workshops. In 8 of the 12 sessions of MSC that have been already completed, the students chose a topic in the field of microbiology and infectious risk (bioterrorism, Ebola virus, risks of waterborne diseases after a hurricane, and the use of antibiotics in intensive livestock farming). Students used original supports to animate workshops (homemade videos, street interviews, live staging, interventions of professionals and quiz)

This ITU, combining problem-based learning and project-based learning, allows a total implication of students in the organization of workshop and obtaining original

teaching and supports on subjects that are not namely taught during their curriculum and prepare them early to scientific communications

**PLACE OF MICROBIOLOGY IN AN INTERDISCIPLINARY TRAINING  
PROGRAMME (MASTER LEVEL) ABOUT THE MANAGEMENT OF GLOBAL  
HEALTH AND NUTRITIONAL SAFETY**

M. Eveillard<sup>1</sup>, N. Ruvoen<sup>2</sup>, D. Lepelletier<sup>3</sup>, S. Couvreur<sup>4</sup>, M. Krempf<sup>3</sup>, C. Magras<sup>5</sup>

<sup>1</sup>*UFR Sciences Pharmaceutiques, University of Angers, Angers, France*

<sup>2</sup>*Microbiology,*

*National College of Veterinary Medicine Food Science and Engineering, Nantes,  
France*

<sup>3</sup>*UFR Médecine, University of Nantes, Nantes, France*

<sup>4</sup>*Filières de production, Ecole Supérieure d'Agriculture, Angers, France*

<sup>5</sup>*Microbiology, National College of Veterinary Medicine Food Safety and Engineering,  
Nantes, France*

**Background**

"Manimal" is a pioneering interdisciplinary training programme (ITP) (Master level) based on the "One World, One Health" concept promoted by international organizations (WHO, OIE, FAO), with an interdisciplinary approach for the management of global health and nutritional safety.

**Objectives**

Microbiology is a topic of great importance for global health and food safety and quality. Our objective was to determine the place of microbiology in this ITP.

**Methods**

This international ITP is organised in 5 thematic teaching units (TU): epidemiology, health: organisation, management and communication, biological and chemical risks, production chains, nutritional contamination and transfers. We particularly identified the interactions developed between microbiology teaching and other TUs in an interdisciplinary perspective.

**Conclusions**

Traditional lectures (face teaching or e-learning sessions) about microbiology are included in the "biological and chemical risks" TU. However, microbiology is also involved in interdisciplinary trainings via student groups around case scenarios (problem-based learning) and visits of production sites to understand the control measures implemented against the development of *Listeria monocytogenes*

(interactions with the production chains TU). Two case scenarios are proposed: "Listeriosis and dairy industry" (interactions with the nutritional contamination TU) and "Antimicrobial resistance" (interactions with all other TUs). Groups containing 4 or 5 students with various initial educations (doctors, pharmacists, veterinarians, biologists, and agricultural engineers) and from different geographic origins (Asia, Africa, Europe) are constituted with the aim to make them solve the problems together. We envisage now to introduce microbiology in tutored projects (project-based learning) and to diversify the microbiological topics in the case scenarios.

**THE SMALL WORLD INITIATIVE AT MCGILL: ENGAGING UNDERGRADUATES IN SCIENTIFIC DISCOVERY AND CROWDSOURCING THE SEARCH FOR NEW ANTIBIOTICS**

S. Gruenheid<sup>1</sup>, C. Trottier<sup>1</sup>, T. Tsang<sup>2</sup>, J. Handelsman<sup>2</sup>

<sup>1</sup>*Microbiology and Immunology, McGill University, Montreal, Canada*

<sup>2</sup>*Microbiology and Immunology, Yale Center for Scientific Education, New Haven, USA*

**Background**

The Small World Initiative (SWI), spearheaded by the Yale Center for Scientific Teaching, is an international, multi-institutional initiative which brings authentic scientific research addressing the real-world problem of antibiotic resistance to undergraduate life science students. SWI students culture soil microbes, screen for antibiotic activity against safe relatives of ESKAPE pathogens, and characterize their positive isolates by classical methods and 16s rRNA gene sequencing.

**Objectives**

McGill launched the SWI program in a sophomore Microbiology laboratory course of 105 students in fall 2014.

**Methods**

During the fall 2014 semester, the students collected soil samples from urban and suburban Montreal and cultured 2,500 bacterial isolates. Following activity screening, 104 isolates were prioritized for further characterization using classical biochemical and microscopy methods and molecular characterization.

**Conclusions**

Of the 104 isolates selected for further characterization, 94 gave positive results in 16S PCR, and of these, 71 yielded high quality 16S sequences. The isolates were equally divided between Gram-positive and Gram-negative, with a wide variety of genera represented. The students were highly engaged throughout the process and reported a high level of enthusiasm in course evaluations.

**FEMS-0642**

**Microbiology education**

**THE DEVELOPMENT OF 'VIRUSES: A PRACTICAL RESOURCE FOR POST-16 BIOLOGY TEACHERS'**

J. Redfern<sup>1</sup>, J. Verran<sup>1</sup>, D. Burdass<sup>2</sup>

<sup>1</sup>*School of Research Enterprise and Innovation, Manchester Metropolitan University, Manchester, United Kingdom*

<sup>2</sup>*Communications, Society for General Microbiology, Manchester, United Kingdom*

**Background**

Practical science activity in the classroom is an essential part of science education in secondary schools. Microbiology, the study of microorganisms (including bacteria, fungi, algae and viruses) relies heavily on practical activity in its teaching. Viruses have significant impact on human activity, encompassing human disease and epidemiology, molecular biology research, treatment of disease and phage-related damage to bacterial starter cultures in food production. These phenomena relate to many aspects of the school teaching specification.

**Objectives**

To develop a new resource containing background information on viruses including real world case studies, three practical activities about viral infection and molecular techniques for diagnosis of viral infection, and guides for teachers, technicians and students.

**Methods**

The booklet underwent extensive formative evaluation in preparation for launch, including trials with students and teachers as well as considerable development in a laboratory setting, in and out of the classroom environment.

**Conclusions**

Subsequently, 'Viruses: a practical resource for post-16 biology teachers' was launched (2013) as an 80-page colour educational resource aimed at post-16 biology education. The resource is freely available to Society for General Microbiology members and is about to undertake extensive summative evaluation.
